14 years. It had been expelled from the left nostril of a girl aged 19 2. A Foreign Body, a pearl collar-stud, impacted in the Glottis of a Child, aged 3. The larynx and trachea, with the stud resting *in situ*, its lower disc caught in the chinks of the ventricles, were exhibited. 3. Injury to the Larynx by Cut-throat in a man aged 41. The vocal cords had been destroyed, but a growth of granulation and cicatricial tissue had taken their place, and the patient was able to speak with a fair amount of phonation. 4. An unusual case of Functional Aphonia in a child aged 6. The loss of voice had followed tracheotomy at the age of two years. Faradisation and tonics had brought about a cure. 5 A Double Acute Frontal Sinusitis following influenza in a boy aged 15. Dr. Davis had operated twice, laying open and draining a large abscess in the forehead, which led into the right frontal sinus by a fistula in the anterior wall; subsequently both sinuses were freely opened and drained into the nose. Discussing the case several members drew attention to the fact that in acute frontal sinusitis with fistula formation it is usually the anterior and not the inferior wall that gives way. 6. A Temperature Chart of a Case of Acute Sphenoidal and Maxillary Sinusitis before and after operation. Attention was drawn to the necessity for routine examination of the nasal accessory sinuses in cases of unexplained pyrexia. (The PRESIDENT also related a case similar to this in which a persistent pyrexia was cured by draining the sinuses) 7. A girl, aged 16 with Lupus of Hard and Soft Palate, Epiglottis, Larynx and both Nasal Cavities, and Lupus Erythematosus on both Cheeks.

Mr. HERBERT TILLEY showed a male, aged 59, who had been tracheotomised 16 years ago for Fixation of Cords in the middle line caused by (?) perichondritis of each cricoarytenoid joint.

Dr. W. JOBSON HORNE exhibited a case of Extensive and Rapid Destruction of the Soft Palate by Specific Disease.

Dr. W. H. KELSON showed a woman from whose trachea a Neoplasm, probably a Papilloma, had been removed.

Dr ANDREW WYLIE showed a boy, aged 7, with a Cystic Condition of the Left Arytenoid, possibly tuberculosis.

Mr. G. WILKINSON reported a case of Severe Epistaxis Associated with Multiple Hereditary Telangiectases in a man, aged 62, in which the hæmorrhage proceeding from the septum had been controlled by cauterisation.

Mr. WILKINSON also showed: 1. (?) Papilloma Removed from the Posterior End of the Right Inferior Turbinal. (The pathological nature of the growth aroused some discussion) 2 A Molar Tooth which he had removed by upper bronchoscophy from the right bronchus; the foreign body had found its way into the trachea during extraction by a dentist.

Dr. W. IRONSIDE BRUCE gave a lantern demonstration of X Ray Photographs illustrating diseases of the accessory sinuses.

Mr. W. G. HOWARTH showed: 1. A case in which an Intrinsic Carcinoma of the Larynx had been removed under infusion anæsthesia with hedonal, to bring to notice the great advantages that this method of anæsthesia affords in laryngeal operations 2. A case of Tuberculous Ulceration of the Pharynx and Larynx. 3. A man with a peculiar Bulbous Swelling on the end of the nose, ascribed by some members to a cyst, by others to a lipoma.

Mr. ARTHUR EVANS showed a patient with Paralysis of the Right Vocal Cord following an operation on the isthmus of the thyroid gland. Mr. Evans suggested the possibility of treating the case by suture of the ends of the recurrent laryngeal nerve, or, failing that, by nerve anastomosis with the hypoglossal branches.

Dr. J. DUNDAS GRANT showed microscopical sections from a case of Tuberculous Ulcer of the Larynx the first section suggestive of epithelioma, the second of non-bacillary tuberculosis, ? lupus.

Dr. WYLIE exhibited a case of Ulceration at the Base of the Tongue in a syphilitic subject.

Mr. F. F. MUECKE showed (1) a large Gumma of the Thyroid Cartilage causing considerable swelling in the neck; (2) a case of Laryngeal Swelling and Ulceration of Specific or Tuberculous Nature; and (3) a patient with Cystic Swellings Projecting from the Sides of both Anterior Nares, probably dental cysts.

Mr. G. W. BADGEROW presented an instance of what looked like Vincent's Angina of the Tonsil in a boy aged 5 years.

Mr. C W. M. HOPE showed a case of Herpetic Vesicles affecting the mucous membrane of the soft palate.

LIVERPOOL MEDICAL INSTITUTION.

Treatment of Wry-neck.—Stones in the Bladder.—Experiences with Salvarsan.

A MEETING of this society was held on Feb. 22nd, Mr. ROBERT JONES the President, being in the chair.

The PRESIDENT referred to the loss that had been sustained by the death of Lord Lister. A vote of condolence with the relatives of the deceased peer was passed by the members standing.

Mr. W. THELWALL THOMAS read a note, illustrated by a case and by lantern slides, on the Treatment of Wry-neck, based on six cases recently treated. Mr. Thomas claimed for his method that, while he got good results, it did away with the long and tiresome after-treatment, as he did not use any retentive apparatus. The operation was on the same principle as that for lengthening tendons. An incision was made transversely over the lower third of the sterno-mastoid muscle, the skin and platysma were retracted, the anterior margin of the sterno-mastoid was freed and cut half through, then the muscle was divided vertically enough to give the length equal to the difference between the two sides, the posterior part of the muscle was then undermined by a director to guard the deep structures and cut. It was often found necessary to divide also bands of deep fascia and in one case other muscle fibres. The ends of the muscle were sutured with 30-day chromic gut without strain and then the superficial wound was closed. The line of the incision did not correspond with the deep wound.—In the discussion that followed Mr. R. W. MURRAY said that he thought the condition was not due to traumatism, but to some defect in ante-natal position, and on this point there was considerable difference of opinion expressed by those who spoke.—The PRESIDENT said that the swellings had been incised soon after birth and found to be œdematous; also the rule was that in rupture of muscle elongation followed. Lorenz was still using the subcutaneous incision with over-correction of the deformity, which could not be done with the sutured wound. He thought the success of these cases depended on careful after-treatment.—Mr. R. C. DUN, Dr. G. C. E. SIMPSON, Mr. D. DOUGLAS CRAWFORD, Mr. F. T. PAUL, and Dr. A. STOOKES took part in the discussion.

Dr C. THURSTAN HOLLAND read a note on Stones in the Bladder, which he illustrated by many lantern slides of radiographs of cases, in several of which an examination by the sound had given negative results, although a stone or stones were found by the X rays. In a large number of cases examined he had never found a stone of pure uric acid in the kidney or ureters, but in the bladder these had been invisible to the X rays. With these rare exceptions he had found the radiographic method much the most trustworthy diagnostic means they possessed. Dr. Holland considered the sound ineffective and dangerous; he thought the cystoscope, also, had much the same objections, but might be useful as confirming the X ray findings. There were a few cases of uric acid stone that did not give enough shadow to be made evident by a radiograph.

Dr. G. S. STOPFORD-TAYLOR and Dr. R. W. MACKENNA read a paper on their Experiences with Salvarsan. They had treated 92 cases. At first they had used the intramuscular injection, but in the later 74 cases had found the intravenous method preferable. No bad results had been seen, but it was important that the patient should be properly prepared. A purgative was given the night before the injection, and next morning a light breakfast, the salvarsan being injected five hours after. It was important to make the solution fresh for each injection, to use saline solution freshly made of water distilled in glass vessels. With these precautions there had been no reaction in most cases, in a few slight sickness or loose motions from the bowels. Elimination took place by the urine in four or five days after a dose of 0·3 grm. and in seven to nine days after a dose of 0·6 grm. The effect on the lesions was immediate. Photographs and lantern slides were shown illustrating the effect on a case of skin eruption. No lesions yielded more rapidly than mucous patches and condylomata; headache at once disappeared; adenitis was the most persistent lesion. In tertiary cases where KI and mercury had failed salvarsan was most valuable. Lesions of the mouth and throat healed rapidly. Iritis was much improved. There was improvement in cases

of general paralysis and in the subjective symptoms of locomotor ataxia, but this improvement had not been maintained. Destroyed neurons could not be restored. One dose could convert a positive Wassermann reaction to a negative in one month, and this might continue for nine months without further treatment. In some cases a single dose will not change the reaction until combined with mercury. The general effect was always an improvement in general health and well-being. As to dangers, death might be caused by this as by any other potent drug. French reports of bad results were biased. No deleterious effect had been seen on the optic nerve. Three cases had relapsed, so that it was always well to reinforce the treatment by mercury, and in all cases a combination of drugs was best. The general conclusions were that salvarsan was effective at every stage of the disease, after mercury and iodide of potassium had failed; that one injection may not cure, the dose should always be repeated and combined; that intravenous injection was better than intramuscular; and lastly, the treatment should be controlled by the Wassermann reaction.—In the discussion that followed Dr. A. J. EVANS agreed with the authors of the paper; he emphasised the need for care in the preparation of the solution. He used a special needle without exposure of the vein for the injection. In cases of congenital diseases there had been no effect on the child from injections given to the mother.—Dr. F. P. WILSON said he had used an emulsion in iodipin for injection intramuscularly. He had found some tertiary cases do better with mercury and potassium iodide than on salvarsan.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 20th, Dr. S. Lodge being in the chair.—Mr. Basil Hughes read a paper on Recent Advances in the Diagnosis and Treatment of Syphilis. He said that the first essential was an early diagnosis. The Hunterian chancre might be difficult to find, atypical, or modified by the presence of soft sore or other mixed infection. Microscopical examination by means of the Indian-ink method for the demonstration of the spirochæta was of great assistance. The presence of indurated glands in the groins was also of great value. Wassermann's reaction he regarded as all-important in the diagnosis of syphilis. He made use of Dr. W. d'Este Emery's method, which had been found to give an accurate result in 98 per cent. of cases. He then described the method of performing the reaction and its explanation by Ehrlich's side-chain theory. Many observers had found a negative reaction in very early cases of syphilis; if that were true it had an important bearing on treatment. The chancre could be excised before the infection became general. The value of Wassermann's reaction was emphasised in cases where the diagnosis would otherwise be doubtful, such as certain ulcers of the tongue, gummata of certain muscles, gummatous adenitis in the groins or axillæ, tertiary laryngitis, gumma of the tonsil, chronic superficial glossitis, and leukoplakia of the tongue, conditions which should always be regarded as syphilitic unless the reaction was negative. Tabetics invariably gave a positive Wassermann reaction; in general paralysis of the insane the cerebro-spinal fluid was also positive, a condition which did not obtain either in tabes or gummatous disease of the central nervous system. Prophylaxis did not receive the attention it deserved. The State should undertake more responsibility in the matter. A strong plea was entered for the more complete treatment of venereal disease in charity-supported institutions, Government subsidies being urged should the funds for that purpose fail. Speaking of mercurial treatment, Mr. Hughes advocated getting the patients under its influence as rapidly as possible. He favoured inunction or intramuscular injections. When physiological limits were reached in the former case gray powder by the mouth might be substituted. Intramuscular injections were more rapid, and for this purpose he advocated Lambkin's cream in weekly doses, numbering about 25, with certain intervals. As with gray powder and inunctions, decoct. sarsæ co. helped the tolerance for the drug. Throughout any course of treatment control by the Wassermann reaction was necessary. It became negative under mercury, but so long as syphilis was still present the positive reaction returned about six weeks after its administration had been stopped. Treatment should be continued until the reaction remained negative for 12 months after treatment had been abandoned. Mr. Hughes believed that this policy would avert many of the late parasyphilitic manifestations, and that cessation of symptoms was no guide as to the cure of the disease. After mentioning the various arsenical preparations which had been tried and abandoned owing to the serious dangers in their employment, he discussed his results by treatment with salvarsan in 100 cases during the last two years. It might be given subcutaneously, intramuscularly, or intravenously. The second method was valuable in certain cases, because its action was spread over a period of some three weeks. But the occasional formation of necrosis and of intractable though aseptic "abscesses" limited its use. He relied mainly on the intravenous method. He described the method of preparation and administration of the drug. He believed firmly that its dangers were entirely due to neglect in the avoidance of cases in whom gross lesions of the fundus oculi, of the heart, of the chest, or of a septic character were present, or to neglect in the careful administration of the drug, which should be injected in a state of perfect solution and of proper alkalinity. The solution must not be spilt in the wound, and a second dose should not be given soon after the first. With these precautions most of the after-results could be avoided. The most important of these were a metallic taste in the mouth, headache, vomiting, diarrhœa, rise of temperature, albuminuria, skin rashes, and rigors. Thrombosis and other embolic dangers could be avoided by care in the preparation and administration of the drug, and anaphylactic phenomena (many of the deaths recorded had been due to a second dose given too soon after the first) by allowing sufficient time to elapse between the doses. In cases showing no active lesion there seemed to be some relation between backache as an after-effect of injection and lesions of the central nervous system. Mr. Hughes gave it as his opinion that a single dose was rarely sufficient, and advised three, the indications for their use, as in treatment by all other forms of methods, being repeated Wassermann reactions. He discussed the simultaneous use of mercury, emphasised the dangers of treatment by "606" in inexperienced hands, and finally insisted on the importance of providing, either by the State or the municipalities, facilities for the performance of the Wassermann reaction in the same manner as it had been made possible nowadays to obtain bacteriological information in cases of diphtheria, typhoid fever, and phthisis.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 21st, Dr. F. H. Jacob, the President, being in the chair.—In opening the discussion as to whether the "Removal of Glands in Malignant Disease was Worth While," Dr. A. Stanley Green said that extensive operations, involving the removal of large tracts of glands and fascia sheaths together with the original growth, were now the order of the day. Surgeons lost sight of their cases, but as a practitioner he was forced to the conclusion that a case was hopeless as regards permanent cure when glands were present. The presence of a microscope in the operating theatre was not an infallible test as to whether the growth was malignant or not, as instanced in a case where, although the testis was reported to be non-malignant, the patient died within three months. Dr. Green then considered operations for malignant disease under four heads: (1) where the glands were not palpably affected—these, of course, gave the best results; (2) where, as in the breast, the growth and glands were removed in one mass; here the results were encouraging; (3) where the glands were removed at a second operation; this was generally a futile procedure, because some of the lymphatic tracts were almost certain to be left between the two operations; and (4) where a further operation was performed for the removal of recurrent glands. Cases were quoted where this was absolutely disastrous. Still, unfortunately at present operation was their only known chance of a cure, for X ray treatment and radio-therapy were at the best only palliative.—The President agreed that X ray and radium only retarded the growth, but warned that they must not be allowed to cause dermatitis.—Mr. W. M. Willis thought that the whole operation for cancer of the breast should be reviewed, and that more consideration should be given to the duration of the disease and the size of the glands. Operation sometimes seemed to light up the cancer. In the oral region the enlargement of glands was often due to sepsis. Each region must be considered separately, and even where the glands were not felt to be enlarged, yet it was advisable

to remove them.—Dr. Sarah Gray said that removal of glands was less favourable in rapidly growing cancer than in more slowly growing cases.—Mr. C. H. Allen remarked that formally mere excision of the growth in epithelioma of the lip was considered sufficient; he, however, thought that better results were obtained by thoroughly removing the glands at the same time.—Dr. W. T. Rowe thought that better results were obtained in tongue cases when the glands were removed as well as the growth; moreover, if recurrence did take place in these cases, it generally occurred in the internal organs and not in the glands.—Mr. A. M. Webber agreed with the last speaker, and said that it was an important thing if the patient could be spared a hideous death from sloughing glands.—Dr. C. H. Cattle said that epitheliomata were of a less malignant type of cancer than carcinomata, also that the glands were less affected in slow growing cancers such as scirrhus of the breast.—In his reply Dr. Green said that in his experience patients suffered more when dying from internal secondary deposits than did those whose glands were not removed.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on March 1st, Dr. Leslie Durno, the President, being in the chair.—Dr. J. Hugh Thursfield gave a lantern demonstration to illustrate some points in the Diagnosis of Children's Diseases. In cases of meningococcic meningitis the extreme head retraction and wasting were well shown, also the wide-open staring eyes. If treated with serum from 40 to 50 per cent. of the cases recover. Flexner's serum is injected into the spinal theca; Göppert's serum is injected under the skin. A peculiar form of rheumatoid arthritis (called Still's disease) is probably an infective disorder. There are spindle-shaped swellings of the small joints of the hands, wrists, knees, and ankles, enlarged glands in the axilla and neck, hectic fever, and enlarged spleen. Cases may last four, five, or six years, and die from an intercurrent disease. Post-mortem examination shows that the actual joints are not diseased, but there is thickening of the soft parts and periarticular structures. The condition is probably due to a bacterial poison formed in the intestine. Cretins are seldom diagnosed before one year old, and it is not true that good results are obtained if treatment is begun very early. A case of tetany in an infant shows œdema of the backs of the hands, with the fingers clenched and wrists flexed. It is seen in rickety and ill-fed children. Localised œdema below the eye, not due to nephritis, is due to whooping-cough, and often precedes it. Birth or Erb's palsy is due to paralysis of the fifth and sixth cervical nerves, and the muscles affected are the external rotators of the shoulder, biceps, coraco-brachialis, and supinator longus. Operative treatment by nerve anastomosis has not been successful, better results being obtained by massage and passive movement. Babinski's sign or the external plantar reflex, where the great toe turns up and the small toes turn in, is, at any age, good evidence of degeneration of the lateral and pyramidal tracts of the cord. In pseudo-leukæmia infantum the spleen and liver are enlarged, and there is chronic anæmia, causing great pallor, and hæmorrhages occur into the spleen, kidneys, skin, &c. It is probably due to an intestinal auto-intoxication. Hirschsprung's disease is a congenital dilatation of the colon, which goes on to perforation and fatal peritonitis. Treatment with enemata and eserine increases the motor power of the colon. Other curiosities shown were: Complete Congenital Absence of the Pectoral Muscles of the Left Side; Heart on the Right Side of the Chest; Extreme Chronic Arsenical Pigmentation; Auto-inoculation of Vaccinia in the Eye; and Congenital Ichthyosis.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 16th in the Glasgow Eye Infirmary, Dr. A. Freeland Fergus, the President, being in the chair, when a clinical and pathological demonstration was given by members of the infirmary staff.—Dr. Andrew Wilson read a short note on three cases of Scotoma Scintillans occurring as a symptom of migraine, and showed diagrams illustrating the fields of vision, and coloured drawings representing the appearances seen by a patient during the attack. Dr. Wilson also showed a specimen of an unusually large Lacrymal Sac excised on account of Dacryocystitis.—Dr. A. J. Ballantyne showed two cases operated on for Ptosis, with satisfactory results, and a case of Concomitant Strabismus, which had followed a fracture of the vault of the skull in the frontal region. In the latter case the strabismus was not due to injury to any ocular nerve or muscle, but had been latent at the time of the accident, and had developed in consequence of the occlusion of the eye by dressing during the healing of the fracture.—Dr. A. Lewis McMillan read notes of a case, the patient being a boy aged 8 years, in which Orbital Cellulitis, occurring as a sequela to scarlet fever, had necessitated enucleation of the affected eye.—Dr. Brownlow Riddell showed a patient with a rare condition of the fundi—Choroideremia, or Gyrate Atrophy of the Choroid and Retina; and three patients illustrating the Pupillary Phenomena in Glaucoma, Iritis, and Tabes Dorsalis.—Dr. M. Logan Taylor made a communication on Malignant Intra-ocular Tumours, based on cases treated in the Glasgow Eye Infirmary during the past three years, and dealing specially with the so-called glioma or neuro-epithelioma. After discussing the lymphatic connexions of the eye and the paths along which the spread of tumour might occur, he particularly emphasised the fact that, in view of our increased knowledge of the pathology of these growths, a more extensive operation for their removal should be carried out as early as possible in all cases. The procedure he recommended was complete exenteration of the orbit with division of the optic nerve at the optic foramen. Dr. Taylor also showed a number of gelatine-mounted preparations of eyes illustrative of a variety of diseases and injuries.—Dr. H. L. G. Leask showed two cases of Penetrating Injury, in which the foreign body was still in the eyeball, or orbit, after many years, as illustrated by radiograms; and a case of Disease of the Ethmoid Cells after successful operation. He also read notes of a case of Intra-ocular Tumour secondary to a scirrhus of the breast.—Dr. W. B. I. Pollock gave a demonstration of specimens of Glioma Retinæ.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A pathological meeting of this society was held on Feb. 16th, Mr. H. Littlewood, the President, being in the chair.—Dr. R. Cattley and Professor A. S. Grünbaum made some remarks on the Genesis of Chronic Arteritis. They said that in syphilitic arteritis the earliest manifestation was an irregular hypertrophy of the internal elastic lamina which was quickly followed by a hypertrophy of the muscular coat. A proliferative thickening of the endothelial and sub-endothelial tissues occurred antecedent to marked degeneration of the muscular and elastic elements.—Dr. Helen G. Grünbaum and Professor Grünbaum communicated notes on Further Experiments on the Treatment of Inoculated Rat Sarcoma and Observations on Certain Accompanying Blood Changes. This paper is published at p. 644.—The President showed Gall-stones removed from a case of suppurative cholecystitis in the third week of typhoid fever. The typhoid bacillus was germinated in the pus.—Dr. C. Oldfield exhibited a specimen showing Hæmorrhage into the Ovary which produced signs and symptoms like ectopic gestation.—Dr. A. L. Whitehead and Dr. M. J. Stewart exhibited a Malignant Tumour of the Lacrymal Gland showing the presence of both squamous and columnar-cell carcinoma.—Mr. H. Collinson and Dr. Stewart exhibited a Scirrhus of the Breast showing fibrosis of the perivascular lymphatics in the surrounding fat. The patient had lymphatic œdema of the arm.—Dr. Stewart showed the organs from a case of Partial Transposition of Viscera. The stomach and spleen only were transposed, while the left lobe of the liver showed marked hypertrophy.—Dr. W. H. Maxwell Telling, Mr. J. F. Dobson, and Dr. Stewart showed preparations from a case of Epithelioma of the Cheek in which the epithelioma was regarded as the result of X ray treatment.—Specimens were also shown by Dr. T. Wardrop Griffith, Mr. B. G. A. Moynihan, Dr. Leonard A. Rowden, Dr. J. B. Hellier, Dr. Clara Eglington, and Mr. W. Thompson.

HARVEIAN SOCIETY.—A meeting of this society was held on Feb. 29th, Dr. H. J. Macevoy, the President, being in the chair.—After the formal business of the meeting had been disposed of, Dr. Farquhar Buzzard opened the discussion on Acute Poliomyelitis and Allied Conditions.—Dr. F. E. Batten dealt with: (1) the experimental production of acute poliomyelitis; and (2) the epidemiology of the disease. The experimental production of acute poliomyelitis in monkeys had been carried out by numerous observers in Austria, Germany, France, and America.[1]

[1] THE LANCET, Feb. 17th, 1912, p. 413.

The virus was filtrable, would withstand the action of glycerine, and if an organism was ultra-microscopic the virus, therefore, had a great similarity to that of rabies. So far only monkeys developed typical poliomyelitis, but the work of Marks had shown that the disease could be transmitted through rabbits without causing clinical manifestations of poliomyelitis in them. The epidemiology was next dealt with, and it was shown that although epidemics had been known in Europe since 1881, yet during the last decade it had been widely spread over the whole civilised world. During 1910 and 1911 numerous epidemics had occurred in England, but how widely the disease was spread would only be known when there was a more general recognition of the symptoms to which the disease give rise and notification was compulsory throughout the country.—Dr. L. G Guthrie, in his remarks, dealt more particularly with the prophylaxis and prognosis in the febrile and afebrile cases. He deprecated the practice of testing the electrical reactions during the acute stage, more especially in young children. He pointed out the importance of massage and passive movement by the mother in those cases where the services of a skilled masseuse could not be obtained. He objected to the use of orthopædic instruments on the ground that usually they were much too heavy for the children to carry.—Dr. Buzzard briefly replied.

Reviews and Notices of Books.

A Text-book of Pathology, with a Final Section on Post-mortem Examinations and the Methods of Preserving and Examining Diseased Tissues. By FRANCIS DELAFIELD, M.D., LL.D, and T. MITCHELL PRUDDEN, M.D, LL.D., Columbia University, New York. Ninth edition. With 13 full page plates and 687 Illustrations in the Text, in black and colours. London: Baillière, Tindall, and Cox. 1912. Pp. 1114. Price 25*s.* net.

ALTHOUGH the name of Dr. Delafield—the senior author—appears on the title page, he no longer shares in the preparation of the work, so that Dr. Prudden is alone responsible for such alterations and additions as have been made in this, as in the last three revisions.

The book covers a wide field, though certain phases of clinical diagnosis and practical bacteriology have been excluded. Some old illustrations have been discarded and 40 new ones added. The author mentions a capital fact when he states that "the successful pursuit of pathology depends largely upon the clearness and accuracy of the student's knowledge of normal anatomy and normal physiology." So far as we can judge from the "introduction," the responsible author seems less at home on the chemical side of his subject than on the purely morphological side. "Proteins and their performances" introduce the reader to "the storm centre of research," concerning which it is stated that we must be patient, and not too eager to carry the formulæ and the working hypotheses of the chemists, without due reserve, over into the domain of living things, whose story and performances, and limitations, we are only just beginning to spell out. To the author "the structure and performances of cells," as the field richest in the promise of significant revelations, is obviously a congenial theme.

Part I. deals with general pathology, Part II. with special pathology, while Part III. is devoted to the methods of making post-mortem examinations and of preserving and examining animal tissues. The illustrations throughout, both coloured and uncoloured, are an outstanding feature of the book. The author's style of expression here and there is sometimes not what we are accustomed to in English text-books. We miss what seems to us rather important, the magnifying power under which the preparations have been observed and figured. The subjects of "regressive" and "progressive" tissue changes are concisely and sufficiently described. Under the technique for neutral fats we failed to find any reference to the newer results obtained with Nile blue. The description of bone grafts is somewhat cryptic. A whole page is given to illustrations of Thoma's frog plates for the study of inflammation. Animal and vegetable parasites occupy about 80 pages. The account of immunity is good, but under anaphylaxis even in the bibliography we find no direct reference to the work of C. Richet, who coined this word. Over 120 pages are given to infectious diseases. The technique for studying such appearances as Negri bodies and the Wassermann and other well-known tests is fully given. The chapter on Malformations, though short, is particularly well illustrated, as is also that on Tumours. Poisons, general diseases, and certain forms of death bring Part I. to a close. One page, however, seems rather too little for pyrexia.

The study of special pathology begins with the blood and blood-forming glands, and the subject is treated much as in other text-books. Considering the recent work on the pituitary body, the space given to it seems rather short. Although it is stated that an extract influences blood pressure and urinary secretion, it is not stated whether it increases or decreases these functions. We miss a reference to the work of Schäfer. The illustrations of diseases of the heart are excellent, and the same may be said of those of the lungs. The names of Mackenzie and Wenckebach are conspicuous by their absence.

This is a text-book much to be commended for the comprehensive survey it gives of pathology, and for the excellent way in which the material changes, as exemplified in morbid anatomy, are depicted in the illustrations and set forth in the text.

The Parasitic Amœbæ of Man. By CHARLES F. CRAIG, M.D., Captain, Medical Corps, United States Army. With 30 illustrations. London and Philadelphia: J. B. Lippincott Company. 1911. Pp. 253. Price 10*s.* 6*d.* net.

THIS monograph, which is published with the authority of the Surgeon-General of the United States Army, gives a detailed description of the various species of amœbæ which have been regarded as parasitic in man, attention being especially directed to their morphology, life-cycle, methods of differentiation, and relation to disease.

The book contains the results of the author's personal observation, extending over a period of more than 12 years, of hundreds of cases of amœbic dysentery, clinically and in the post-mortem room. Much of his material was gathered during his service in the military hospitals and while he acted as a member of the Army Board for the Study of Tropical Diseases in the Philippine Islands. He was moved to prepare the present volume by finding that most of the works dealing with the subject were written in German, French, and Italian, and that there was no publication in the English language treating fully upon the parasitic amœbæ of man. A further incentive to prepare the work was the fact that amœbic dysentery is now recognised to be of much more frequent occurrence, even in the temperate regions of the United States, than was formerly believed.

The book is divided into nine chapters, and about half of the space is devoted to the consideration of the amœbæ of the intestinal tract, and especially of Entamœba coli, Entamœba histolytica, and Entamœba tetragena. A short description is given of the amœbæ of the mouth, of the genito-urinary tract, and of those found in exudations or abscesses and in the lungs. The author admits that the position of some of the species described cannot be regarded as permanent, it being probable that further research may result in their elimination from the list. Details are given of a number of experiments on animals carried out by himself, presumably in the Bacteriological

Laboratory of the Army Medical School, Washington, and in the Rockefeller Institute for Medical Research in New York.

This useful monograph is likely to fulfil the expectations of the author, who intended it originally for the use of medical officers of the United States Army, Navy, and Marine Hospital Service, and of public health officials and practitioners in districts affected by amœbic dysentery. It gives a very clear and concise account of the state of our present knowledge of these parasitic amœbæ of man, and their distribution, morphology, mode of reproduction and life-cycle, cultivation, and relation to disease. A valuable bibliography, consisting of a list of more than 120 references, is appended, and a useful index is also supplied.

Diseases of the Ear, Nose, and Throat. By WENDELL CHRISTOPHER PHILLIPS, M.D., Professor of Otology, New York Post-Graduate Medical School. With 545 illustrations, some in colours. Philadelphia: F. A. Davis Company; London: Stanley Philips. 1911. Pp. 847. Price 25*s.* net.

Dr. Phillips has set himself an ambitious task in writing a book which is to meet the needs of the general practitioner and the surgeon as well as the otologist and the laryngologist. He says that he has purposely refrained from perpetuating distorted theories or descriptions of operations which are obsolete or have been succeeded by more modern methods, and that his aim has been to write a practical, accurate, and concise treatise supported throughout by personal experience. The number of pages is not excessive for the threefold subject, and unnecessary space has been taken up in describing "the office equipment," as it is called, and in showing a nice little photograph of his own "treatment room." We should have preferred a rather larger amount of space to be devoted to the examination of patients, especially to the physical part of the examination.

The first part of the book, occupying nearly 400 pages, deals with diseases of the ear, and in considering the tests for hearing we find that the author thinks that if only two tuning forks are employed they should be the C2 and C4. The usual tests are briefly considered, but, as in a good many modern text-books, a very full description is given of the various tests employed in attempting to clear up difficulties in labyrinthine diagnosis.

The second part of the book is on the influence of general diseases upon the ear, nose, and throat, to which, practically speaking, another 100 pages are devoted, such diseases as tuberculosis and lupus receiving, of course, a very full description. Dr. Phillips does not describe in this place the direct method of operating on the larynx, and certainly some subjects coming under the section now under consideration are treated very cursorily. For instance, asthma receives only 26 lines, whereas the next two pages are devoted to the testing of blood pressure, with diagrams of instruments for ascertaining the pressure.

The next portion of the book, describing diseases of the nose, occupies approximately 150 pages. The operation of sub-mucous resection is very fully and carefully set out, with full sheet illustrations of all the various instruments required, though many others are given besides in the text. Ash's operation is also included. Diseases of the pharynx, naso-pharynx, and oro-pharynx between them occupy about 80 pages, while the larynx has to be content with 60, part of which is taken up by several large anatomical drawings. In fact, it is in this part of the book that condensation has been most rigorously carried out. The last part of the book is devoted to laryngoscopy, tracheoscopy, and bronchoscopy.

We have no doubt that in future editions Dr. Phillips will revise the methods of treatment, and see that the direct method is introduced to his readers at the commencement and not at the end of their studies. The present arrangement is scarcely in keeping with his stated intention of eliminating the obsolete and introducing the most modern methods, for most certainly the indirect method of laryngeal surgery is to no inconsiderable extent a thing of the past. It is much less nervous work operating by direct than by the indirect method. The results are more certain, and the technique when once mastered is relatively quite simple.

Dr. Phillips has produced a book which will no doubt fulfil the requirements of a large number of medical men and students, though we hardly think it thorough enough for specialists.

Die Experimentelle Pharmakologie als Grundlage der Arzneibehandlung. By Dr. HANS H. MEYER and Dr. R. GOTTLIEB. Second edition. Berlin and Vienna: Urban und Schwarzenberg. 1911. Pp. 554. Price, paper, 12 marks; cloth, 14 marks.

THE fact that this is the second edition of a book which made its first appearance in 1910 is evidence that the work is of sterling value, and that it has found the ready welcome which was to be expected from the reputation of its authors as pharmacologists. The application of pharmacology to the problems of medicine is prominent throughout, and with this idea in view the subject matter has been arranged, not, as is usually the case in such text-books, in chapters, each dealing with a group of similar drugs, but in sections corresponding to organs and systems of organs. Thus we have chapters on the pharmacology of the motor nerve-endings, the central nervous system, the eye, digestion, and so on. In addition to a very full description of the actions of drugs on the various organs, a useful account of the chemistry of the more important substances is given, and a most helpful discussion on the relation between constitution and physiological action is included.

Among the more prominent new features of this edition are the copious additions which have been made to the chapter dealing with the pharmacology of the generative organs. The treatment of this subject is lucid and complete. The chemical influence which an organ (e.g., an ovary) exerts, through the agency of the substances that it secretes, upon the general development and functions, upon another organ of the same system, and upon more or less distant organs, is fully discussed. We are reminded, however, that but little is known of these internal secretions, which evidently afford a wide field for bio-chemical research. The pharmacological relations of the lacteal glands and the uterus and its movements receive ample attention, as do the physiological actions of a large variety of agents. Especially noteworthy is the description of ergot, its action, constituents, and mode of employment, an account of the important recent work of Barger and Dale and their co-workers being included. These investigators appear, to a large extent at any rate, to have solved a problem which has been for many years the object of attack from all sides; they have isolated the complex active alkaloid ergotoxine and the very active bases *p*-hydroxyphenylethylamine and 4-β-aminoethylglyoxaline, the two latter having been previously separated from the decomposition products of flesh. A third active substance of the putrefaction-base class, agmatine, which, however, is not mentioned in the book under review, has been obtained from the drug by Engeland and Kutscher.

One of the most useful chapters in the last edition was that dealing with the relations of pharmacology to the causes of disease, and much new material has now been added to this section, which treats the subject in an exhaustive manner. An interesting feature of the matter found under the heading "General Antiseptics" is a discussion of the differing

germicidal powers of various disinfectants, depending upon their ability to penetrate the protoplasmic lining of the bacterial cell. This penetrating power is due in some cases (e.g., phenol) to the solubility of the antiseptic in this protoplasm, and in others to the destruction of the lining layer by the poison. The effects of a third group of agents are the result of both actions. The acids, salts, and bases having disinfectant action fall chiefly into the second group, and it is shown that their activity depends on their degree of ionisation in solution; thus mercuric chloride is more ionised than the corresponding bromide, and this than the cyanide, the germicidal powers of these salts falling into the same order. The general antiseptics and anthelmintics and the specifics and their action are very thoroughly reviewed, special attention being given to the organic derivatives of arsenic and their poisonous influence on the protozoa. Antitoxins, serum-therapy, and immunity are also fully treated.

At the end a new chapter has been added in which are collected several problems of general pharmacology that were previously to be found in various parts of the work. These are chiefly connected with the conditions necessary for and affecting the therapeutic action of potent drugs. Defects in the book are really scarce; a constitution is ascribed to antipyrin, however, which cannot be reconciled with the synthesis of the substance from methylphenyl-hydrazine and ethyl acetoacetate. The addition of an index of authors' names, or at least the inclusion of these in the general index, would be an improvement. The references given are copious, including much recent work, and the diagrams are remarkably clear, coloured ink being used in many cases. The authors are to be congratulated upon a masterly treatment of their subject.

A Text-book of Experimental Psychology, with Laboratory Exercises. By CHARLES S. MYERS, M.A., M.D. Cantab., Sc.D., of Gonville and Caius College, University Lecturer in Experimental Psychology, Cambridge. Two Vols. Second edition. With 1 plate and 66 figures and diagrams. Cambridge University Press. 1911. Pp. 344 and 107. Price 10*s.* 6*d.* net.

WE extend a cordial welcome to the second edition of Dr. Myers's well-known text-book. By the separation of the systematic from the exercise part of the work reference from one to the other is rendered more easy. A considerable amount of new material has been incorporated. Much of the matter of psychological interest dealt with by Dr. Henry Head in his recent Croonian lectures on the Sensory Functions of the Thalamus and Cortex[1] is included in this edition, and the original text has been subjected to a thorough revision. Chapters on cutaneous, visceral, auditory, labyrinthine, motor, visual, gustatory, and olfactory sensations are followed by others on memory, muscular and mental work, psycho-physical methods, muscular effort, binocular and binaural experience, the visual perception of size and direction, time and rhythm, feeling, and attention. There are not a few questions of psychological importance on which Dr. Myers adopts a "not proven" position, quoting rival theories and placing them with conspicuous fairness before the student, at the same time criticising their defects and encouraging the latter to form his own conclusion. In paragraphs on psychological topics of secondary importance—as, for instance, those on the so-called "central" sense of muscular effort—the reader will find the same admirable scientific spirit exemplified. The qualities of lucidity and conciseness enhance the value of the book. The bibliographies at the end of the chapters are very serviceable. The series of exercises fulfil their purpose satisfactorily.

No worker in psychology can afford to dispense with this excellent text-book, while the physician opening it at random will find material to engross him on almost every page.

[1] THE LANCET, Jan. 6th, 13th, and 20th, 1912.

LIBRARY TABLE.

Materia Medica, Pharmacy, Pharmacology, and Therapeutics. By W. HALE WHITE, M.D. Lond., M.D. Durh. (Hon.), Senior Physician to, and Lecturer on Medicine at, Guy's Hospital. Twelfth edition. London: J. and A. Churchill. 1911. Pp. 695. Price 6*s.* 6*d.*—The fact that a work has reached a twelfth edition is sufficient proof of its value and popularity, and no words are needed from us as to its nature and scope. Dr. Hale White's book has been found to be one of the very best treatises on the subject, and the present edition maintains that position. Every care has been taken to bring it thoroughly up to date. The letterpress is not confined to a description of official preparations, but many that are not official are also considered, so that a vast amount of useful information has been collected together. The form in which the subject matter has been arranged and the essentially practical character of the remarks alike command attention and reward perusal. We cordially recommend this manual as valuable both to students and practitioners.

New Tracts for the Times: 1. *Problems of Sex.* By J. ARTHUR THOMSON and PATRICK GEDDES. 2. *Womanhood and Race Degeneration.* By MARY SCHARLIEB, M.D., M.S. Lond. 3. *National Ideals and Race Regeneration.* By the Rev. R F. HORTON. London, New York, Toronto, and Melbourne: Cassell and Co., Limited. 1912. Pp., in one vol., 63. Price 6*d.* a volume.—These "New Tracts for the Times" are published under the auspices of the National Council of Public Morals, a body whose end is race regeneration. And although the movement for race regeneration is apparently a novelty, it must be remembered that thinkers in all ages have written and spoken on the subject, for the wish and the desire to make men better has been the ideal of many leaders of thought from Plato through St. Augustine down the ages to the Dominicans and Franciscans, More and the Quakers, Wesley and Whitfield, the writers of the old Tracts for the Times, and impersonal societies such as University and other "Settlements," which are at work in our large towns. The three tracts before us do not suggest remedies or methods of operation, but state in simple language the ideals which should be aimed at. Professor Thomson and Professor Geddes, professors respectively of zoology in the University of Aberdeen and of botany in the University of St. Andrews, are well known for their researches into, and writings upon, sex problems, and they have written an excellent little book treating the subject from the evolutionary and biological points of view without in any way glossing over or minimising the dangers and difficulties which attend the sex impulse which is at once "the glory and the shame of mankind." We have rarely seen a work in which the canon is so forcibly and plainly laid down that "uncontrolled sexuality cannot remain a purely personal vice." It may seem strange in connexion with the problems of race degeneration to refer to a French romance, but many persons will read novels who will not read "tracts" or scientific treatises, and there is a book by Claude Farrère, called "Les Civilisés," which preaches a sermon on self-control, pointing out the terrible wreckage of human lives which follows its absence, and insisting incidentally on the duty which parents owe their children to bring them up in the way in which they should go. The sermon if read aright makes it plain to all who read that the wages of sin is death.

Mrs. Scharlieb's paper deals with the training of women, woman's influence on the race, and on women as citizens. All three chapters are sound and sensible. Mrs. Scharlieb

does not spare her own sex in one matter at any rate—namely, their tendency to be hard and exacting as employers. She lays especial stress upon the need to a community of a religion. We agree with her. It is not our province to insist upon one religion more than on another, but we are certain that no race or country can flourish in which men do not remember the dictum laid down by an easy-going Epicurean heathen—namely, Horace—who told his countrymen to remember

Dis te minorem quod geris, imperas.

The Rev. R. F. Horton discusses National Ideals, and, in his first chapter, the question What is a Nation? Incidentally, too, he discusses the relation of the British nation to the Empire. The problems of national ideals naturally connote political questions, and here again it is no business of ours to take sides, but there is one remark of Dr. Horton's which, judging by articles and correspondence in the daily press, may be cordially recommended to politicians of all complexions. It appears on p. 51, and runs as follows: "Suffer anything rather than lie; recognise that no good cause, least of all the best, can ever be served by lying."

Selbstbefreiung aus Nervösen Leiden. Von Dr. Med. WILHELM BERGMANN, Lietendem Arzt an der Kaltwasserheilanstalt in Cleve am Niederrhein. Freiburg: Herdersche Verlagshandlung. 1911. Pp. 295. Cloth, 4*s*.—This little volume is intended as a sort of "manual of self-help" for all whose "nerves" are the weakest and least healthy part of their organism. The author feels that mere consultations with a physician can do relatively little towards putting such patients on their feet again, in a metaphorical sense, inasmuch as his time is of necessity limited, and he can as a rule only point out the way; it is in the carrying out of his instructions that the patients fail. What is wanted is some dynamic to inspire and stimulate them to renewed effort on their own behalf in the absence of the physician. Mental re-education will accomplish much if the patient knows how to set about it. The author takes the nervous patient into his confidence and indicates how by daily exercise of his own faculties the latter can escape from the pessimism and depression under which he labours. The language of this "manual" is simple and untechnical, and the book may with advantage be put into the hands of those who can be brought to believe that they can work out their own salvation. There is nothing that is novel and much that is hackneyed in its pages, and it may be questioned whether the author's methods are applicable to all the cases of functional nervous disease, a description of which he supplies in the first part of the book. There can be no doubt of his sincerity and enthusiasm; at the same time, the frequent use of the familiar "du" and a superabundance of poetical and other quotations give the impression of a certain tendency to "preach" which may be calculated, we think, to defeat its own ends. We can admire, however, the spirit in which the book has been written; its general tone and the hopefulness of its outlook deserve hearty commendation.

Contributions à l'Étude du Traitement des Tuberculoses Externes par des Injections Modificatrices. Les Injections d'Huile Gomenolée. Par Dr. JACQUES TRIBES, Ancien Externe des Hôpitaux de Paris, Interne de l'Asile National des Convalescents des Hôpitaux de Paris à St. Maurice. Paris: A. Maloine. 1912. Pp. 82. Price 2 francs.—The author here presents the results of his investigations carried on for two and a half years at the Hôpital Bretonneau and the Hôpital Trousseau. He gives a historical *résumé* of the treatment of external tuberculous conditions by various injections, going back as far as Fabricius ab Aquapendente, who injected oxymel to disperse tuberculous fungosities. He describes the various agents that have been employed—iodoform, camphorated naphthol, and camphorated thymol—and finally gomenol, which his pamphlet is written to advocate. Gomenol is a distilled extract of the young leaves of a variety of *Melaleuca viridiflora*. Its characteristics have been determined by Professor Bertrand, of the Institut Pasteur at Paris. The preparation used by Dr. Tribes is a 20 per cent. oil of gomenol, about 1 to 2 c.c. being injected. He claims that considerable quantities can be deposited within the affected tissues without inducing intense inflammatory symptoms or intoxication. He describes the technique, and gives a series of cases. The thesis obtained the bronze medal of the Assistance Publique.

MISCELLANEOUS VOLUMES.

DURING the last few days we have received for review a good many novels. We can only spare space to say a few words about some of them, but this is not because we consider that novels make little appeal to the medical man. On the contrary, the number of our readers who also read novels appears to be quite large. *The Chink in the Armour*, by Mrs. BELLOC LOWNDES (London: Methuen and Co., Limited. 1912. Pp. 316. Price 6*s*.), is a thoroughly good sensational story. Mrs. Belloc Lowndes knows her types to their finger nails, can invent a *millieu* for them that exactly suits the parts which they have to play, and writes with ease and distinction. She also has the rare gift of being able to produce thrills; we cannot particularise the parts in her story where this admirable quality were particularly in evidence without disclosing the details of the plot, and that in the case of this story would be unpardonable.—*In a Cottage Hospital*, by GEORGE TRELAWNY (London: T. Werner Laurie. 1911. Pp. 241. Price 2*s*. net). What are the conditions that according to Mr. George Trelawny obtain in the smaller hospitals of the country? In "Rebley Hospital," as depicted by him, the nurses and ward sisters are nearly all women of loose character; the matron habitually neglects her duties to run after a hypocritical and dipsomaniac preacher, and doubles her income by means of secret commissions from the tradesmen, in which last offence most of the hospital committee are also implicated; pages are devoted to descriptions of most brutal ill-treatment of the patients, who, moreover, are subsisted habitually on putrid food, for the profit of the matron and the secretary; the "hospital comforts" are stolen by the nursing staff from the patients' bedsides, wherewith to treat their male guests at their orgies in the nurses' parlour, where they pass their time in drunken lewdness with members of the visiting staff and the committee; nearly all the honorary medical staff are incompetent, and the one more or less competent surgeon attempts brain operations in a state of drunkenness with callous indifference to their fatal results; another member of the visiting staff stays away from the hospital for weeks, and even months, ostensibly to play golf, but really, it is suggested, to spend the time with one of the nurses, for four out of five of the staff have their paramours among the nurses. Nurses, matron, and medical staff drive without any regard for decorum to a public *fête*, where they become the worse for drink in public. The senior surgeon (a professional abortionist, by the way, who keeps a record book of his malpractices), while drunk, induces abortion in the hospital with fatal results on a nurse of whose condition he is himself the author, and to whom the unsophisticated house surgeon, in ignorance of her obviously wanton character, has become engaged. Failing to fasten the guilt on the innocent house surgeon—who, by the way, had also misconducted himself with the victim—he poisons himself. And lest there should be any doubt of the author's meaning,

the closing words of the book (in italics) are: "Reader, there is many a Rebley Hospital in England to-day!" while the preface says that the details "are true in substance and in fact." It is a matter for wonder that any publisher should be found willing to put his name to such a childish and malignant work.——If humour really possesses restorative power as is asserted, *Letters from China and Some Eastern Sketches*, by JAY DENBY (London: Murray and Evenden, Limited. 1911. Pp. 438. Price 6*s*.), deserves to be read by every medical man, not only for his own entertainment, but to recommend as a possible auxiliary to treatment in certain cases. Its humour is really humorous without being coarse, while those who are acquainted with Shanghai will appreciate the fidelity of its limning. The book is perhaps distinctly reminiscent of various writers, but they are all at least praiseworthy models. For instance, the "Letters from China" remind one at not infrequent intervals of Mark Twain and again of Jerome. Of the shorter sketches, some —e.g., "The Griffin"—recall Kipling's "Plain Tales from the Hills"; others—e.g., "A Question of Method"—Anthony Hope's "Dolly Dialogues." But they have also a spirit of their own; they are no mere copies. It is a fresh and exhilarating book.——The preface to a twelfth edition of *Round the Red Lamp*, by Sir CONAN DOYLE (London: Methuen and Co., Limited. Pp. 224. Price 1*s*.), consists of an extract from a letter by him to an American correspondent, in which he says: "The province of fiction is to treat painful things as well as cheerful ones. The story which whiles away a weary hour fulfils an obviously good purpose, but not more so, I hold, than that which helps to emphasise the graver side of life. A tale which may startle the reader out of his usual grooves of thought and shock him into seriousness, plays the part of an alterative and tonic in medicine, bitter to the taste, but bracing in its results." An excellent statement of the case, so long as judgment is exercised in the selection of the patient for the remedy. But as a book about medical men by a medical man the "facts and fancies of medical life" detailed in "The Red Lamp" have proved, and will doubtless continue to prove, interesting reading for medical men. ——A decidedly interesting story to while away a leisure hour is *A Giver in Secret*, by THOMAS COBB (London: T. Werner Laurie. Pp. 253. Price 2*s*. net). The secret gift on which the title is founded is an unknown benefaction of £500 to a charming young orphan daughter of an adventurer, at the very time when certain facts point to her as the possible thief of jewels from the cousin of the man to whom she is engaged. The sudden change in her circumstances, which she can explain only by what appears to be a cock and bull story, naturally leads to complications, the serious effects of which, however, disappear on the arrest and confession of the actual thief. But there is no anti-climax even then, for interest is still retained while seeking the anonymous giver. The story is well told, except for a certain trying tendency to run on without break or stoppage in the same chapter to events that are subsequently discovered to involve a change of time and place from that under consideration in the preceding sentence.

Of books of personal reference one would think there was an ample supply, what with "Who's Who," and various professional, philanthropic, artistic, literary, and other Guides and Directories. Yet the *Personal Calendar, a Monthly Index of Political, Official, and Social Changes* (London: E. Mansfield and Co. No. 1, January, 1912. Price 6*d* monthly, by post 7*d*), fills an undeniable lacuna. Year books of personal reference clearly become more and more out of date with each passing month. Fresh births, deaths, marriages, appointments, retirements, promotions, and honours occur from day to day, and the task undertaken by this unpretentious little pamphlet is to keep the year books fully up to date. The cumulative index of names, which occupies nine columns of small print, shows how much has been condensed into 34 pages. In addition to the January happenings there is also a December supplement, suggested by the fact that annual books of reference go to press some weeks before their nominal date of publication, Jan. 1st. It is possible that this little work will soon become as indispensable as our annuals now are.—— Another reference work is *The Matriculation Directory* for January, 1912, published by the University Correspondence College, Burlington House, Cambridge, and Red Lion-square, London (price 1*s*.). It supplies the intending graduate of the University of London with a summary of the regulations governing the various examinations for degrees and with the questions set at the last matriculation examination. Answers to these questions are fully worked out and, where necessary, illustrated. Information is also given as to the scope and relative difficulty of the obligatory and optional subjects.—— Most medical men at some time or another require information as to the different Insurance Offices. The *Insurance Register* (*Life*) for 1912 (London: C. and E. Layton. First edition. Pp. 152. Price 1*s*), now in the forty-third year of publication, will give them information as to the various English and American Companies, a Directory of Companies, general statistical information, the comparative rates of the various offices, and such like. It is proposed in future to issue three editions in each year—in January, May, and September respectively.——*Layton's Handy Newspaper List* for 1912 (London: C. and E. Layton. Pp. 167 Price 6*d*) is now in its twenty-second year of publication. It gives the titles, price, date of establishment, politics or class, and address of all the principal daily, weekly, monthly, and quarterly papers and periodicals in the United Kingdom. The towns in which the various journals are published are aranged alphabetically, with the exception of London, which comes first.

JOURNALS AND MAGAZINES.

Quarterly Journal of Experimental Physiology. Edited by E. A. SCHÄFER, F. GOTCH, W. D. HALLIBURTON, C. S. SHERRINGTON, E. H. STARLING, and A. D. WALLER. Vol. IV., No. 4. London: Charles Griffin and Co., Limited. 1911. Pp. 305–397 + vii. Price 6*s*.—1. Kenneth Mackenzie (Freeland Barbour Research Fellow, Physiological Laboratory, University of Edinburgh): An Experimental Investigation of the Mechanism of Milk Secretion, with Special Reference to the Action of Animal Extracts. After a short introduction on what was previously known regarding the origin and mode of conveyance of stimuli influencing the growth and secretory activity of the mammary gland, the author describes his own experiments. The first person to show conclusively that animal extracts containing hormones may directly stimulate the mammary secretion was Ott, of Philadelphia, who found that "infundibulin is a galactogogue" (October, 1910) The author made extracts of the following five organs and injected them into a vein in cats in varying stages of lactation: pituitary body, corpus luteum, pineal body, lactating mammary gland, and involuting uterus. The mammary gland is, as regards its secretory activity, not under the direct influence of the nervous system, so that the agents which excite or inhibit its activity reach it by means of the blood-stream. The five organs above enumerated produce hormones which stimulate the activity of the gland, and in this respect the galactogogue substance of the posterior lobe of the pituitary body is most powerful. This substance is not specific to mammals, it is also present in the pituitary gland of the

bird. Hormones which inhibit the milk secretion are produced by the fœtus and placenta. Drugs, such as pilocarpine, which cause marked activity of most other glands, and others, such as atropine, which inhibit most glands, have no effect on the secretion of the mamma. The author comes to the conclusion that there are no secretory nerves in the mammary gland, a conclusion supported by the fact that neither section of the nerve trunks supplied to this gland nor their faradic stimulation appears to have any influence on the secretion of milk. 2. T. Graham Brown (Carnegie Fellow), Physiological Laboratory, University of Liverpool: Studies in the Physiology of the Nervous System (No. IX.); Reflex Terminal Phenomena; Rebound; Rhythmic Rebound and Movements of Progression. This is a most elaborate research into the phenomena which occur in that phase of a reflex action which immediately succeeds the cessation of the stimulus, and persists until the primary state of balance is again attained. It is a continuation, extension, amplification, and verification of much work already done and foreshadowed by Sherrington, with the addition of much new matter on a very important, but highly technical, aspect of reflex action. It is an extremely thorough piece of work, which cannot be summarised, indeed the author's own "summary" extends to three pages. It will be specially interesting to physiologists and neurologists, who, however, must be conversant with the nomenclature of the subject in order to follow with profit the intricacies of the problems so fully illustrated and discussed. This part also contains the index for Vol. IV.

Reports and Analytical Records.

FROM

THE LANCET LABORATORY.

EUCERIN.

(P. BEIERSDORF AND CO., 7 AND 8, IDOL-LANE, LONDON, E.C.)

EUCERIN is a very interesting fatty substance which is described as the "hydrophile" of wool fat—that is to say, it is the constituent chiefly responsible for the water-absorbing properties of lanoline preparations. It has been shown that the water-absorbing capacity of wool fat is not due to the cholesterin bodies, but to other wool-fat alcohols. Recently these alcohols have been isolated in a more or less pure state, and the result is a product which forms the active water-absorbing basis of a cool and soothing ointment. It suffices, for example, to mix but 2 per cent. of it with vaseline to form a fatty mixture which will absorb as much as 500 per cent. of water. It is obvious that there is a wide field for eucerin, because it presents clear advantages over fatty bases hitherto in use. Being a powerful absorbent of water, it follows that it will have cooling soothing properties, while it is practically odourless and free from liability to become rancid. Anhydrous eucerin is a jelly-like looking mass which readily takes up water, forming a pure white creamy-looking paste. It is perfectly compatible with a good many medicaments of acknowledged value in the treatment of skin diseases.

(1) PATENT BARLEY; AND (2) PATENT GROATS.

(KEEN, ROBINSON, AND CO., LIMITED, DENMARK-STREET, ST. GEORGE'S-IN-THE-EAST, LONDON, E.)

1. This method of preparing "patent barley" is neat. The facility, for example, with which barley water may be prepared from it renders it very economical in use; it yields its important constituents to boiling water more readily than ordinary pearl barley. Barley water possesses properties the reason for which do not clearly appear. It is well known, for example, that it assists in the assimilation of milk in infant-feeding by preventing apparently the casein from separating into large clots when it comes into contact with the acid juices of the stomach. It also acts as an agreeable demulcent, a property which is probably due to substances other than starch, while being a wholesome and refreshing beverage. 2. "Patent groats" offer advantages similar in character to patent barley. They are free from cuticle and irritating particles and yield a maximum amount of their food constituents when prepared in the ordinary way. The sample examined was free from a certain oily smell which ordinary oatmeal sometimes possesses, and the result, after cooking, is a gruel, bland and smooth in character.

(1) SPECIAL OIL SILK; AND (2) WATERPROOF SHEETING.

(NEW PEGAMOID, LIMITED, 134, QUEEN VICTORIA-STREET, LONDON, E.C.)

The fabrics submitted to us proved to be excellent examples of oil silk. They are impervious to water and resist perfectly the action of the antiseptics commonly used in medical practice. We made a number of experiments, endeavouring to act upon the material with solutions containing respectively carbolic acid, corrosive sublimate, formaldehyde, boric acid, iodine, and so forth. There was no destructive action in any case, but iodine led to a slight discolouration. Even hot alcohol did not appear to take out any serious amount of the wax veneer. Boiling water, although in the presence of antiseptics, does not harm the material. The specimens submitted to us comprised a series of oil silks of different colours and a waterproof sheeting which seems to us to be very well adapted for hospital work. When heated with caustic alkali the waterproof coating was removed and left behind a pure cotton fabric. The alkali contained a fatty acid.

JUNORA.

(MESSRS. HUMPHREY TAYLOR AND CO., 45, NEW OXFORD-STREET, LONDON, W.C.)

This is described as a wine containing products derived from lecithin-ovo, and the description was confirmed by our analysis, since it disclosed the presence of choline and of organic phosphates. By suitable treatment the crystalline platinum salt of choline was obtained. Further, when analysis was directed to the separation of ordinary phosphates from organic phosphates, the total phosphoric acid found (P_2O_5) on complete oxidation was 0·0461 gramme per 100 c.c., while the phosphoric acid due to inorganic phosphates was found to be 0·0220 gramme per 100 c.c. The difference therefore, 0·0241 gramme, represents the phosphoric acid present in organic combination (glycerophosphate). The presence of organic phosphates explains the claim made for this wine in regard to its value in nutrition. The amount of organic phosphoric acid found represents a little over 1 grain of lecithin per fluid ounce, since lecithin contains 8·8 per cent. of phosphoric acid. The lecithin employed is prepared from egg yelk by a process which we have seen in operation. Further examination gave the following results. Alcohol by volume, 16·24 per cent.; extractives, 9·48 per cent.; sugar, 7·35 per cent.; glycerine, 0·574 per cent.; volatile acidity reckoned as acetic acid, 0 12 per cent.; fixed acidity reckoned as tartaric acid, 0·27 per cent. The basis is a sound wine of a delicate character.

DECODOL.

(AGENTS: THOS. CHRISTY AND CO., 4, 10, AND 12, OLD SWAN-LANE, UPPER THAMES-STREET, LONDON, E.C.)

Decodol is described as a dry emulsion of cod-liver oil, protein, and carbohydrates, a description which was borne out by analysis. We found it to contain moisture, 6·72 per cent.; mineral matter, 4·68 per cent.; cod-liver oil, 28 00 per cent.; carbohydrates, 26·56 per cent.; protein, 34·04 per cent. Decodol is a light brown powder with oily

touch and smell. It is a highly nutritive compound which should have many special purposes.

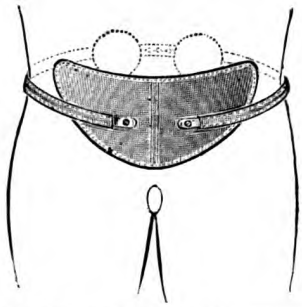
PROTEIN FOOD WITH ORGANIC PHOSPHATES.
(R. HOGG AND SON, 1, SOUTHWICK-STREET, LONDON, W.)

Our examination of this food confirmed the description of it to the effect that it is prepared with casein and glycerophosphates. We found it to contain 76·55 per cent. of protein, 7·90 per cent. mineral matter, and 14·30 per cent. moisture. The mineral matter contained a little more than half its weight of phosphoric acid. The preparation is well made and an important feature about it is that it softens very readily with water, forming a uniform pulpy mixture to which milk or water can be added. The powder is thus uniformly distributed, and the fluid so prepared is free from coarse lumps or unsoftened particles.

New Inventions.

A NEW ABDOMINAL SUPPORT.

THE abdominal support here illustrated has been designed in accordance with the suggestion of Mr. Arbuthnot Lane, with the object of providing a constant support in enteroptosis, visceroptosis, post-operative cases, floating kidney, anteversion of the uterus, varying forms of hernia, and so forth. It consists of two triangular aluminium plates with the vertical edges running parallel to each other and hinged together by a covering of soft leather. The pressure pad thus formed for covering the whole of the lower abdomen is kept in place by two half circular springs which are pivoted to the plates in front and terminate at the back in two soft elliptical pads.

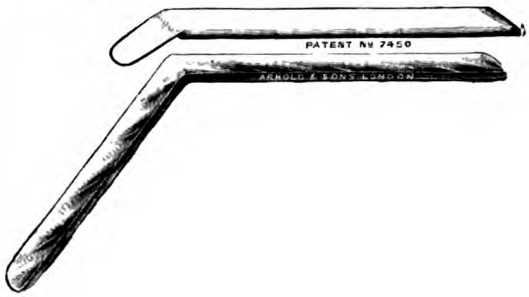


These back pads help to distribute the pressure, which can be varied by the use of light or heavy springs. The direction of the pressure can be varied by altering the position of the springs. The support fits comfortably to the body, and the advantages which are claimed for it are: direct antero-posterior pressure of any desired degree; the springs being shaped to fit the pelvis, there is no binding or cramping the hips; it will keep its position on almost any shaped abdomen, without the use of perineal straps; it is applied or removed by means of one strap and stud, and is easily done in half a minute; being made of metal it has a longer life than any ordinary belt, without being any heavier.

Messrs. Walton and Curtis, 190, Broadhurst-gardens, West Hampstead, London, N.W., are the manufacturers.

ENVELOPE FOR TONGUE DEPRESSORS.

MEDICAL inspection of school children has its own problems, and one of these is the efficient examination of the throat without the risk of carrying infection from one to the other by the tongue depressor. Boiling or steaming the instrument is in nearly all cases impracticable. Disinfection by chemicals has many disadvantages. To obviate these a great number of medical officers use wooden depressors which are burned immediately after use. This is a safer and cleaner method than by the use of one common depressor for all, whatever the disinfectant employed. Wood, however, has also its disadvantages: it is too bulky for carrying about; it is not pure white and so does not reflect the light; and where there are no open fires, and in summer time when there are no fires at all, there is a practical difficulty in getting them burned. A very simple expedient, and one which has several good points in its favour, has been patented and placed on the market by Messrs. Arnold and Sons, Giltspur-street, London, E.C. It consists of an envelope made of specially prepared paper which fits on to an angular depressor. The portion applied to the tongue is of double thickness, so that there can be no risk of organisms passing



through. At the proximate (open) end there is a "tab" on which the finger rests to steady the envelope. This also serves as a catch by which to pull off the envelope after use, thus preventing any portion which has been in the mouth coming in contact with the medical officer's fingers. The small amount of room they occupy in the wallet, the enhanced "illumination" of the throat by the white paper, the facility with which the envelopes can be burned and disposed of, together with the efficiency in preventing throat-to-throat infection, should make this little contrivance a most useful item in the school medical officer's outfit. The same advantages will also commend it to the general practitioner.

DONALD MURRAY, M.B., C.M. Glasg., D.P.H. Aberd.
Stornoway.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* The chair of Mental Diseases, until recently held by Dr. Ziehen, has been offered to Dr. Karl Bonhoeffer, Professor of Psychiatry in the University of Breslau, who was formerly Professor in Königsberg and afterwards in Heidelberg. As he is only 43 years of age his promotion has been remarkably rapid. If he accepts the present invitation he will have occupied the chair of his specialty in four German universities in nine years.—*Breslau:* Dr. Erich Feiler has been recognised as *privat-docent* of Odontology.—*Prague:* Dr. Alexander Skutetzky, a military surgeon in charge of the medical wing of a garrison hospital, has been recognised as *privat-docent* of Medicine.—*Rennes:* The chair of Chemistry has been divided into two, one of Analytical and Toxicological Chemistry, and one of General Chemistry, Dr. Lenormand, the present professor, taking the first, and Dr. Laurent, Professor of Pharmacy, the second. To the chair of Pharmacy Dr. Perrier has been appointed.—*Vienna:* It is now stated that Dr. v. Noorden, one of the professors of medicine, will not leave Vienna for Frankfort, as he was expected to do.

STATE AID FOR RESEARCH IN MENTAL DISORDERS.—At a meeting last week the visiting committee of the Cardiff Mental Hospital passed a resolution expressing its opinion that it was desirable that State aid, in the shape of grants, should be sought in the domain of research in mental disorders, such grants to be distributed through the Commissioners in Lunacy, as is done in the case of research in public health through the Local Government Board. It was pointed out that such research is liable to be expensive, and, since it is of national and not merely of local importance, it does not seem reasonable that local authorities should have to find all the funds. The results of researches made with the aid of such grants would be published in the Lunacy Blue-book. A further resolution was recorded to the effect that the town clerk circularise the public asylums and registered hospitals of England and Wales with a view to ascertaining whether they were prepared to join, in the first place, in approaching the Commissioners in Lunacy in the matter in order that the latter might make a representation to the proper quarter.

THE LANCET.

LONDON: SATURDAY, MARCH 9, 1912.

The National Insurance Act and the Modern Interpretation of the Hippocratic Oath.

THE famous "Oath" of HIPPOCRATES is probably the earliest extant recognition, on the part of a distinguished practitioner of medicine, of the nature and extent of the obligations of the members of his calling towards their predecessors, their patients, and the public; and it is interesting just now to inquire in what degree the principles underlying it may be considered to have stood the test afforded by the experience of some 2300 years, and to retain their applicability to the conditions of our present environment. At a period when instruction in the healing art is not only readily available, but is offered in return for payment by many competing schools and institutions, it is perhaps unreasonable to regret the weakening of the bond between teacher and pupil which has manifestly occurred since the "Oath" was framed; and there is still much reason to hope that, although the pupils at a modern hospital and school no longer regard the physicians and surgeons of the staff as being "equally dear to them as their parents," they nevertheless retain towards many of them very strong feelings of affection and respect, founded upon a correct appreciation of their several characters and endowments, and upon a grateful recollection of the benefits conferred by their teaching. The expressions of personal regard which have been evoked during the last few weeks by the deaths of Lord LISTER, Sir HENRY BUTLIN, and Sir WILLIAM ALLCHIN prove that the sentiment enjoined by HIPPOCRATES is strongly developed with us. The undertaking to impart a knowledge of the healing art, with certain filial exceptions, only to "disciples bound by a stipulated oath," manifestly contains the germ of the obligation now entered into by the newly affiliated in many of the modern licensing bodies, in the shape of a promise to maintain the honour of the fraternity into which they have been granted admission, and to bear themselves in a manner worthy of the members of a benevolent and honourable calling. And, if we may assume that the "stipulated" oath was identical in its terms with that in which it is referred to, we find that it simply amounts to an undertaking to practise uprightly and honourably, to live cleanly, to refuse assistance to would-be poisoners, abortionists, or suicides, and to preserve secrecy with regard to the private affairs of patients and of their households. We must perforce admit that the increased complexities of modern life have added to the responsibilities of practitioners, and have created new standards of duty in relation to contingencies of various kinds; but the fact remains that the foundations of these standards are as old as the practice of medicine, and that they were plainly set forth by the father of our art before the visible dawn of the Christian ethics which they nevertheless embody. The most upright of modern practitioners might add to the "Oath" of HIPPPOCRATES in matters of detail, but could take nothing away from it, and would be compelled to admit that his additions were of detail only, and were, in all essentials, practically comprised within the simple and stately language of the original.

A remarkable omission from the "Oath," however, regarded by the light of more modern experience, is that it contains no explicit reference to the duties of practitioners towards each other, an omission probably due to the comparative scarcity of physicians at that period of the world's history, and to the consequent rarity of the occasions on which they could be brought into collision. But circumstances having changed, and human nature being what it is and always has been, we now have the difficulties among us engendered by professional competition. The claims of rival medical practitioners are necessarily of a kind only too likely to lead to the mortification of him who fails to make good his ascendancy, and mortification too often means loss of self-control, with loss of dignity to follow it. But we conceive that the very requirement of the stipulated oath from pupils, between whom it must have formed a bond of considerable tenacity, was in itself a definite, even if only an implicit, recognition of admission into a brotherhood; and it is probable that the matrons of Cos, however critical of the way in which a practitioner should behave, were afforded but slender opportunities of instituting damaging comparisons between candidates for their fees, who would almost certainly have been taught that the only way to secure the respect of the public was to show respect to one another. We greatly doubt whether the physicians of the Hippocratic era would have suffered loss of self-command to lead them into the spitefulness of opponency which unfortunately became characteristic of a period of brilliant literary and scientific awakening in Europe and in England, a period which furnished MOLIÈRE with his medical types, and which survived in this country at least until after the exchange of bitter epigrams between Dr. GEORGE CHEYNE and Dr. WINTER, or the publication of the successive editions of Dr. GARTH'S "Dispensary." May we not now recognise a return to the self-control and forbearance of an earlier age, and an increasing recognition of the duty of respecting the position assumed by brethren in the art, even on occasions when we cannot recognise its complete advisability or accuracy. The gifted President of the Royal College of Surgeons of England, whose loss we have lately had to deplore, is quoted as having declared that the medical man has three duties, "his duty to his patient, his duty to his profession, and his duty to himself." The Hippocratic Oath seems to us, in its essential characters, to leave none of these duties unregarded or unprovided for, and those who abide by its prescription will find themselves in possession of a code as practical as it is inspiring.

And if ever there was a time in which it was necessary to strengthen the tie of professional brotherhood by every

argument which can be founded either upon the precepts of antiquity or upon the experience which has been garnered since those precepts were originally framed, surely that time is the present. We are face to face with the fact that an Act of Parliament has been passed which, though professedly framed for the encouragement of national thrift, in its present shape threatens the very existence of the profession of medicine. Important sections of this Act might entail, if they were carried out in the manner intended by those who framed them, and if no safeguarding regulations are forthcoming, the committal of many thousands of the labouring population of this country to the professional care in sickness of medical men who would be so badly remunerated as to render it impossible for that care to be in any way representative of present day standards either of diagnosis or of treatment. Even in the existing state of public business such an Act could hardly have been passed had it not been for the appalling ignorance of the average politician on all matters connected with or arising out of science; an ignorance which, in relation to health questions, was lately declared by a medical writer to be dependent on the fact that the average member of the House of Commons had usually obtained his notions of medicine in the nursery, and from a nurse to whom they had been handed down by her grandmother. Throughout the debates on the Act there was displayed by speakers on either side of the House little clear comprehension of the essentially scientific character of good medical work, of its difference in point of principle either from a handicraft, in which any common man can acquire proficiency, or from a profession like the law, in which every point hitherto decided is set down in books, and is so available for reference as often to place the novice on the same plane as the more experienced. But it was allowed in the House of Commons, in words, that no man of ordinary capacity can do his duty to the sick under the continued pressure of sordid cares, and hence that a proper remuneration of the medical profession, as a body, is essential to a complete utilisation of their powers as guardians either of private or of public health. A serious diminution in the aggregate of medical incomes, especially occurring at a time when many of the necessities and comforts of life are steadily rising in price, would immediately check the flow of students from the classes which now chiefly furnish them; would compel a lowering of the cost, and a consequent impairment of the quality, of medical education; would recruit the profession from the comparatively untaught; and would not only lower the moral and the intellectual tone of its followers, but would place grave impediments in the way of research and of discovery. From such evils as these it is the duty of all practitioners to protect at once their own body and the public, and they can only do so effectually by presenting a united opposition alike to menaces and to blandishments, and by absolutely refusing to take any contracts under the Act except upon terms which will yield a proper and reasonable return. Our duties lie in the future, and in such a display of unity in our ranks as may convince the most sceptical of our determination, and may show that the brotherhood, which is at least indicated in the spirit of the Hippocratic Oath, has survived the lapse of centuries without diminution or decay.

The Discovery of Anæsthesia.

IN an interesting paper, the first part of which appears in another column, Dr. DUDLEY W. BUXTON urges the right of Dr. CRAWFORD W. LONG to be regarded as the pioneer of anæsthesia. The other protagonists are relegated to a position less prominent, as whatever their claims CRAWFORD LONG had anticipated them in the discovery. The dramatic events following CRAWFORD LONG'S pioneer work are grouped about HORACE WELLS, C. T. JACKSON the chemist, and W. T. G. MORTON. None of these men, it appears, knew of CRAWFORD LONG'S work, and only one of them, JACKSON, possessed any scientific knowledge concerning ether. WELLS in 1844 had noticed that during nitrous oxide inhalation those who inhaled became unconscious of pain. He determined to administer the gas, doing so from a bladder, to assuage the pain of tooth extraction. The trials proved successful, and he with MORTON, who had been his pupil and partner, gave a public demonstration. This was, however, a fiasco, and apparently WELLS forsook his "discovery."

MORTON still sought for practical anæsthesia. Having terminated his partnership with WELLS he built up a lucrative practice as a dentist and aspired to a medical qualification. This ambition brought him into touch with JACKSON, whose pupil he became. Chloric ether was commonly used by dentists, and MORTON noticed that after applying it to the tooth the gum tissues were obtunded. This suggested the use of chloric ether as an anæsthetic, and so JACKSON experimented with it, but when employed for human beings it was a failure. It will be recalled that this same drug was tried in some London hospitals soon after SIMPSON'S announcement of his success with chloroform, but again its use was accompanied by failure. Nothing daunted, MORTON requested JACKSON to supply nitrous oxide for his patients. The latter suggested sulphuric ether as being easier to obtain and kindred in action. JACKSON knew these facts as common knowledge among chemists. MORTON was unaware of the action of ether and, possessed by the courage of ignorance, he obtained sulphuric ether and experimented with animals. Success attended his efforts. The next step was to test his discovery upon himself. Inhaling from a long-necked bottle—"Morton's sucking-bottles," as Dr. WESTCOTT so contemptuously termed them, when "Morton-baiting" had become a fashionable pastime among dentists in Boston—he became nearly asphyxiated. Then a handkerchief soaked in ether was substituted and alone in his room MORTON felt himself passing into unconsciousness, as he describes it, with a sickening horror lest there should be no awakening. He had noted the moment of commencing to inhale, and when he awoke he found that he had been unconscious for seven minutes. Such experiments done on oneself evince courage and grit, even if the supreme dangers courted are but vaguely appreciated. That same night to MORTON came EBEN FROST to have a tooth extracted, and, being a fearful soul, he begged to be mesmerised. The chance had come; MORTON'S assurance of "something better than mesmerism" appealed to the man with the aching premolar whose state brooked of no delays. The ether was given, the tooth taken out, and FROST

remained stark in the chair. Again the haunting horror assailed MORTON—was the man dead? MORTON applied the water test by emptying a bowl in FROST'S face. This happily caused a rude awakening, and MORTON hoped that for him had come fame and fortune.

It is interesting to note that, as BIGELOW relates, MORTON'S first essay to etherise a private patient in a surgical operation nearly ended in disaster. Luckily MORTON knew his medical shortcomings and had asked BIGELOW to be present, who happened to observe that over-stimulation had resulted in circulatory exhaustion, and observed it in time. In 1846 MORTON obtained permission to demonstrate "Letheon" in the Massachusetts General Hospital, and WARREN removed a venous tumour. Other equally successful demonstrations took place, and the world acclaimed "Letheon," alias sulphuric ether, to be a success. No one would willingly depreciate the credit due to MORTON for his perseverance and courage. His position as a person knowing practically nothing of the scientific side of anæsthesia was none the less an easier one than was that of CRAWFORD LONG, for the former had brilliant surgeons to support him, while the latter, in a remote country township, was divorced from sympathetic professional brethren. The facts as we know them seem to support the thesis that CRAWFORD LONG, without external suggestion or support, elaborated the idea of ether anæsthesia and successfully practised it before anyone else; that HORACE WELLS initiated nitrous oxide anæsthesia two years later, but did not recognise that though his theory was correct his technique was so faulty as to be foredoomed to failure; that JACKSON passed on second-hand knowledge to MORTON, but had no part or lot in the practical application of that knowledge to produce anæsthesia; and lastly, that MORTON, although actually years behind the true discovery of anæsthesia, yet gave up his lucrative profession and applied the energies of his life to the promotion of what he regarded as his own discovery—ether anæsthesia. He possessed courage, resource; he experimented and he succeeded, having the backing of powerful friends.

Annotations.

"Ne quid nimis."

THE MENACE OF THE COAL STRIKE.

THE complete stoppage of the national coal-supply at its source has already become a terrible menace to the health as well as to the prosperity of the country. Business has been dislocated in a thousand quarters, and in many has definitely come to a standstill. Vast numbers of workers whose industry is bound up with the coal-supply, sometimes only in an indirect manner, are being thrown out of employ, or are labouring from day to day on short notice. Concurrently with this cessation of wages the price of food and fuel and of other necessaries is rising, and must continue to rise while the terrible position lasts. Not that the position can last much longer as it is; inevitably, unless relief comes, the approaching condition will be much worse than the present. Difficulties and delays in transport and production must soon lead not only to a general advance in prices, but to an actual shortage of supplies, and what this will mean to the sick and the young requires no exposition in a medical journal. The interference with the sanitary services and water-supplies of the community, to which we alluded a fortnight ago as forming the gravest threat to the health of the country, has already commenced, and those who know the possible gravity of the situation require all their calmness to wait silent day by day for the signs of a more reasonable and humane spirit among those responsible for our perilous plight. But that calmness must be maintained. Upon the sick, upon those who have the care of the sick, upon the over-worked, and upon the poorly paid, the mere tension engendered by the necessary self-control will have its evil effect, an effect that the statistics of mortality will assuredly reveal to us; but it is absolutely necessary that all who are rendered by more favourable circumstances strong enough to bear the strain should bear it calmly. Scurrilities against coal-miners and coal-owners, Premiers and Chancellors, Tories and Socialists, may temporarily relieve the ass who utters them, but they add to the anxieties of the ass who believes them. This is not the time for wild and whirling words: it is the time when those who feel that they can help their weaker brethren should take thought as to the most practical way in which their services can be rendered.

AN "APOCRYPHAL" MIRACLE EXPLAINED.

A CASE has recently been described in the Danish medical press[1] which, according to a correspondent, throws light on a miracle related in the Apocrypha. The patient was a man of 77, whose right lens was completely cataractous, but whose eye was otherwise normal. The cataract, which had existed for about eight years, had not been operated upon, as it did not interfere with the patient's work as a road-mender and as the sight of the other eye was excellent. While at work in his garden one day the patient had occasion to rub his right eye several times on account of sweat which had trickled into it. He awoke next morning to find that the sight of his right eye was restored; his wife and neighbours also remarked that his eye no longer looked grey. On examination by a doctor five days later nothing was to be seen of the lens till the patient looked down, when it was seen as a grey, shining body floating in the vitreous humour at the bottom of the eye, where it moved with the movements of the eye. On certain movements of the eyeball the lens appeared covering half the pupil, but it quickly slipped back into its former position at the bottom of the eye. The capsule of the lens was nowhere to be seen, nor was the eye painful or tender on pressure. The vision of the patient's right eye gradually improved, and during an observation period of over a year no inflammatory reaction or increase of the intraocular pressure occurred. The miracle related in the Apocrypha happened, of course, to Tobit, who slept with his eyes open in the courtyard of his house. A passing swallow discharged its fæces into his eyes, both of which became covered by a white membrane. His physician could do nothing for him, but his son, called Tobias, meeting the angel Raphael, was conducted by him to the river Tigris, where he caught a large fish the gall-bladder of which he was told to open. The bile was dripped into the father's eyes, when the covering membranes fell off, after the patient had rubbed his eyes violently. Professor Greef in his account of this miracle as portrayed by Rembrandt, suggests that Tobit must have suffered from a pterygium, as this is a common condition in the East, and as the disappearance of a white membrane is mentioned. He negatives the possibility of the condition being due to cataract, which cannot, he states, be cured

[1] Jespersen, Hospitalstidende, Dec. 3rd, 1911. Lundsgaard, ibid., Dec. 20th, 1911.

by external manipulation. The painting by Rembrandt in Brussels depicts the young Tobias performing an operation for cataract on his father. In the Lutheran translation of this miracle the word leucoma is freely translated as cataract, which is retained in the Dutch Bible of to-day. Greef's hypothesis is the less credible, as it is highly improbable that bile rubbed into the eye could remove a pterygium, whereas it is conceivable that old Tobit rubbed his eye vigorously after the instillation of bile, and that he thereby dislocated his lens. If this be the correct interpretation, Rembrandt's painting is at fault only with regard to the cataract needle held by Tobias. The painting is the best portrayal of an operation for cataract which has hitherto been made, and Rembrandt was presumably assisted by v. Meekren, an old pupil of Tulp, whose views as to the impossibility of curing cataract by external manipulations probably coincided with those of Greef. According to yet another theory Tobit suffered from a serpiginous ulcer of the cornea which is treated to this day with the instillation of bile. But such a cure cannot have been so spontaneous and rapid as the restoration of sight by the dislocation of the lens which, as the above case shows, may occur with that suddenness which is one of the essential features of a miracle.

THE PROBLEM OF THE DIPHTHERIA CARRIER.

THE importance of the apparently healthy carrier of infective organisms in regard to the spread of many specific infectious diseases has become increasingly apparent since attention was first drawn to the question in the case of enteric fever. The recognition of this factor in their spread has opened out a new field of work in the prophylaxis of some of these diseases. In none is the problem of greater importance than in the case of diphtheria, and the difficulties in the way of dealing with the carrier of the bacillus of this disease render any careful study of this question noteworthy. We have received a monograph entitled "A Study in Epidemiology illustrated by a Diphtheria Epidemic," privately published by Dr. Angus Graham Macdonald, in which, among other matters, this question of carrier cases is considered in some detail, and in which a scheme is suggested for endeavouring to deal with it. The basis of his observations is afforded by a careful study of an epidemic of this disease occurring in Crewe during the months from March to August, 1910.[1] Ninety carrier cases were isolated in association with 157 cases notified. The contacts were divided into home and school contacts, and there were 534 of the former yielding 62 positive cases or carriers, and 644 of the latter with 28 carriers. In addition 774 bacteriological examinations for release from quarantine were carried out, yielding a total of 2326 examinations. All school-carriers were found to be intimately associated at play with other cases and with carriers, but mere class-room proximity was found to be of little importance as a factor in spreading the disease. The evidence also goes to show that very intimate means are necessary for the transmission of diphtheria from one individual to another—a point which Dr. Macdonald regards as of great importance in indicating how readily the dissemination of the disease may be prevented by prompt bacteriological examination and detection of positive contacts or carriers. These carriers are divided by the writer into four definite groups—first, those who show no clinical evidence of diphtheria in whom the bacillus is found for a short time; second, cases in which there is a history of "cold" or "sore-throat" some time previously, these being probably neglected cases of diphtheria. The third group comprises patients without clinical history of diphtheria, but presenting some local lesion in the throat, nose, skin, or ear, in which the diphtheria bacillus finds lodgment, the commonest example being membranous rhinitis. The fourth group is made up by patients who have passed through a definite attack of diphtheria, and in whom the bacillus remains for lengthy periods after convalescence. The fate of the bacillus when it disappears is not obvious. There is no evidence of phagocytosis, and the suggestion offered as the most probable explanation is that it disappears as a result of the growth of some other organism. The administration of antitoxin appears not to influence the existence of the organism either in case or carrier. Dr. Macdonald sums up his observations upon carriers in a series of statements, among which we may mention that the length of carrier-life of the bacillus appears to have no effect upon its virulence, since the organism has been proved to be virulent after four and eight months in the ear and nose. He maintains that the control of diphtheria depends on the control of the carrier as well as of the case, and he urges that the carrier should be notified, no matter of what age or sex, and that due quarantine and observation should be maintained until satisfactory disappearance of the bacillus. He believes that a determined attack on the disease on the lines of thorough bacteriological investigation should have no difficulty in stamping out diphtheria altogether. He claims that the distribution of the disease which persists endemically is due to undiscovered carriers, and that epidemicity depends entirely on the number and nature of the carriers. After a critical examination of all the facts collected in relation to the particular epidemic investigated, Dr. Macdonald outlines his scheme for dealing with the disease. It affirms that a bacteriologist should be an essential member of the public health staff. He recommends isolation in a case as early as possible after notification and adequate disinfection. In the investigation of each case he advises a thorough inquiry into the history of the patient and into his environment, and urges that swabs should be taken from the patient, from all home contacts, and from as many outside contacts as possible. Until bacteriological reports are obtained all contacts are to be isolated. All contacts found to be positive are to be treated as cases of diphtheria. Dr. Macdonald's monograph is a thoughtful and suggestive study of a complex problem, and deserves to be carefully considered as a practical contribution to the study of preventive medicine.

[1] THE LANCET, March 25th, 1911, p. 795.

THE STUDY OF TROPICAL DISEASES.

A MEETING was held on Wednesday, Feb. 28th, at the Mansion House, by permission of Sir Thomas Crosby, M.D., the Lord Mayor of London, in support of the London School of Tropical Medicine, when Mr. Lewis Harcourt, the Secretary of State for the Colonies, delivered an impressive appeal for the public support of the school. He detailed the vast and valuable work which had been done in our far-off dependencies to mitigate the ravages of tropical diseases, or to discover and eliminate their causes, and claimed on good grounds that the keepers of the national purse had not been niggardly in their contributions to the work. A few days later H.S.H. Prince Louis of Battenberg, taking the chair at the annual dinner of the London School of Clinical Medicine, supplied additional arguments for public digestion why the people of this country should endeavour to support, and support profusely, the grand medical work now being done throughout the borders of our vast Empire. The medical services, Naval, Military, and Colonial, are now collaborating with

private workers and scientific missionaries from our universities and schools of tropical medicine in a manner that bears new fruit every day. The movement is the direct adjuvant to our rule as an Empire; for only by subjection of the inimical forces of disease can we as a nation come into full enjoyment of much territory that bears our name on the atlas, or discharge our duty as a superior race to those whom we have invited to depend upon us. Medical men have sacrificed their lives for this cause; the way for the public to make such sacrifices unnecessary is to facilitate the great object which medical men and sanitarians have in view, and support the multifarious movements now taking place to wipe out disease in our tropical possessions.

THE PAY OF THE PUBLIC ANALYST.

THE remuneration of the public analyst has seldom been upon a scale consistent with the training, skill, and experience which are required of him, but now that the practice of adulteration is becoming such a refinement, requiring a very elaborate series of operations for its detection, the scale of fees in many instances is wholly inadequate. There can be little doubt that modern methods of adulteration are often the product of a subtle scientific mind which discreditably turns its attention to the possibilities of eluding the control over the purity and quality of food, drugs, and drink provided by the Sale of Food and Drugs Acts. No analyst nowadays, if he is an honest man, dare certify that a sample, say, of butter is genuine without determining not only the amount of butter fat present, but the nature of the fat also, a process which involves considerable skill and attention. Then he will estimate the amount of water, curd, salt, and will search for preservatives, of which there are so many, and when found he will be bound to estimate the quantity in order to be able to say whether that is permissible. He is expected to do all this for, say, 10*s*. 6*d*. It may be urged that some compensation is arrived at because other samples which come before him may include substances which give very little trouble so far as their analysis is concerned. Accepting that for a moment, we doubt then whether the average fee for analysis is a fair remuneration for the high qualifications now required for the post. The days when 10*s*. 6*d*. was an ample reward for casting a specimen of suspect coffee upon the surface of water and noting whether some of the particles rapidly sank, colouring the water on their downward way, which meant the presence of chicory, are gone. The public analyst's work now is work of the highest scientific order; it must be done by a competent and conscientious man, otherwise the administration of the food laws must soon fall into disrepute. Slovenly practice must be impossible if discredit of the public analytical service is to be prevented. And there should be no temptation in the shape of totally inadequate pay to shirk the carrying out of a duty in a thorough and effective manner. The machinery which guards the purity and quality of our food-supply must be efficient, and it is impossible to purchase efficiency at rates which are so low as to give no recompense for training, skill, and responsibility. Only recently advertisements have come to our notice which invite qualified analysts to apply for a post which involves the analysis of 800 samples of foods and drugs per annum, and the remuneration offered is an annual sum of £150. In another instance the analyst is required to provide and maintain a laboratory himself, together with apparatus, chemicals, and assistance "as are necessary to enable him *adequately* and *completely* to execute the duties of the office." (The italics are ours.) The work means examining and reporting upon 2000 samples, formal and informal, per year and the remuneration offered is £500. The "informal" samples might mean the performance of some very elaborate analyses indeed, which at 10*s*. per analysis could not possibly meet the expenses of the "apparatus, chemicals, and assistance" laid down in the advertisement. The living wage is left entirely out of the proposition, and such a policy must sooner or later bring discredit upon a very important department of public service.

SUCCESSFUL ARTERIOTOMY FOR EMBOLISM OF THE FEMORAL ARTERY IN A CASE OF MITRAL STENOSIS.

THE recent operation of arteriotomy for embolism has not given the results which the remarkable experimental researches of Carrel led us to anticipate. Probably this is due to the fact that most of the operations have been done on aged subjects with diseased arteries containing long adherent clots. At a recent meeting of the Société de Chirurgie M. F. Lejars, commenting on the failure of the operation in one case, suggested that better results might be obtained in young subjects whose arteries were sound. At a meeting of the Académie de Médecine on Dec. 19th last M. Mosny and M. Dumont reported the following case in which this proved true, and fatal gangrene of the lower limb was prevented. A man, aged 38 years, was admitted into the Saint-Antoine Hospital suffering from cardiac dyspnœa. The heart was dilated and extended two fingers' breadth to the right of the sternum, the apex beat was in the anterior axillary line, the left auricle was manifestly dilated, and there was a presystolic thrill, but auscultation did not reveal any particular valvular lesion. The heart's action was very rapid and irregular. The liver was only slightly enlarged, and there was no dropsy or albuminuria. The patient gave a history of dyspnœa on exertion since childhood. Under rest and digitalis he improved, and a typical double mitral murmur could then be heard. The heart diminished in size and the arterial tension rose, but the pulse was still irregular. One morning, at 6 o'clock, when he was getting up for the tenth time since his admission, he felt a severe pain in the left calf, which he compared to an intense cramp. This rendered the whole limb powerless. When seen three hours later there were manifest signs of femoral embolism. The foot and leg, but not the thigh, were cyanosed, livid, and "marbled" in places, particularly on the great toe, by whitish completely ischæmic patches. The limb was cold as high as a well-marked limit four fingers' breadth above the patella. Sensibility was abolished up to the knee and movements of the foot and leg were impossible. No arterial pulsation could be felt in the limb except in the femoral artery in the upper part of Scarpa's triangle, Examination of the artery did not reveal any pain. Embolism in the upper third of the femoral artery, probably at its bifurcation, was diagnosed, and immediate operation was decided upon. Six hours after the onset of symptoms. under local novocaine anæsthesia, M. Georges Labey laid bare the artery in its upper third and incised it where it did not pulsate, and sensation of resistance showed the presence of a foreign body. The vessel was opened for a distance of one centimetre, and by compression a bifurcated clot extending from the common femoral into the superficial and deep femoral arteries was removed. The artery was sutured and the blood current was re-established. The operation, which took only a few minutes, was well borne. The limb was warmed by hot-air douches. Two hours after the operation the limb was warm and the cyanosis was diminishing. On the following morning the limb had regained its normal appearance, sensibility and motility had returned, and the popliteal artery pulsated. Thirty-six hours after the operation pulsation was distinct in the posterior tibial. At the time of the report (a month after the operation) the good result was maintained and the limb was quite sound, but the

patient was confined to bed by the condition of his heart which was dilated and irregular in action. M. Labey is to be congratulated on this remarkable success, but M. Mosny has gone too far in claiming this as the first successful case. In 1909 Dr. J. B. Murphy, of Chicago, in another case of mitral stenosis successfully removed an embolus from the common iliac artery, restoring the circulation.[1] This was a very daring operation in which it was necessary to catheterise the abdominal aorta and remove clot from it. The patient did not come under treatment until four days after an embolus was arrested at the bifurcation of the aorta; the limb was undergoing dry gangrene, and a line of demarcation had formed four inches below Poupart's ligament. Such complete success as in the preceding case was therefore impossible. Pulsation returned throughout the femoral artery, and amputation was performed at a lower level than would otherwise have been possible. Another and simpler method of treating arterial embolism has been used with success by French practitioners. It consists in breaking up the clot by massage *(pétrissage)* into small particles which are carried by the circulation to smaller arteries where a collateral circulation can be established, and they are no longer a source of danger. We reported a case of femoral embolism from mitral disease in which this was successfully done by M. Paul Claisse.[2] It is curious that this eminently rational and simple procedure has been overlooked, and the same treatment for arterial as for venous obstruction—rest—is recommended in the text-books. But this treatment could not have been adopted in the case now reported, because for success it must be adopted immediately after the embolism occurs.

FEBRUARY AT HOME AND ABROAD.

THE intense cold early in the month occurred when the barometer was low, a circumstance not usual in this country. Very severe frost sometimes happens with a low barometer, but it is generally quite transient, rarely continuing for more than 24 hours. But in the present case, although the glass was low, the pressure distribution was favourable for winds from some point between north and east, and the cold was, to a large extent, brought to these islands by the flow of air from those quarters. No sooner did the relative positions of the highest and lowest barometric pressure areas allow the air to flow from the south-east and south than the temperature rose rapidly to above freezing point, and as throughout the remainder of the month there was a continuous flow of air from between south and south-west the thermometer remained very high for the time of year, with the result that, in spite of the almost Arctic cold of the early days, the mean temperature was far in excess of the average for February. Very soon after the month began the frost became so severe that there are few occasions during the past 20 years which can furnish a parallel. The lowest thermometrical reading of the sheltered instrument in these islands appears to have been 4° above zero at Balmoral, but on the grass or snow the exposed thermometer sank to a few degrees below zero in several parts of the kingdom. At Norwich there was a reading of 3° below. Later in the month the thermometer rose to 50° and above with uncommon frequency for February, and on several occasions ascended to above 55° in the south and south-west of England, while the high figure of 60° was recorded at Great Yarmouth and at Birr in central Ireland. In the metropolis the mean temperature of the month was about 4° above the average. At Westminster and Greenwich the mean of the maximum readings was 49°, and at Kew and Hampstead 47°, while the mean of the minima was 38° at Kew, Greenwich, and Hampstead, and 40° at Westminster. These figures prove that as usual the central parts of London were appreciably milder than the outlying suburbs. Both at Greenwich and Westminster the thermometer rose to 50° or above on 19 afternoons, at Kew on 15, and at Hampstead on only 12. Comparatively few days were quite rainless, but the aggregate amount of the fall was not very much in excess of the average. The largest total was 1·76 inches at Hampstead and the smallest 1·39 inches at Kew. Over the country as a whole the rainfall exceeded the average and the sunshine was in default. In the southern and south-western counties of England this year has, so far, been very dull. In the metropolis last month there were 14 hours of bright sunshine in the City, 26 hours at Westminster, 27 at Hampstead, 35 at Kew, and 38 at Greenwich. Along the south and south-west coasts the figure, although much higher, was still below the normal, and on several days the sun was not seen at all. In the southern regions of Europe the earlier days of the month were more or less rainy, especially on the Riviera and in Spain. At Nice rain fell very frequently during the first nine days and yielded a total of 5 inches. Subsequently, however, the Riviera enjoyed the bright and warm sunshine generally associated with that favoured region. At Nice the mean afternoon warmth was 55° and that of the night 41°. This is rather warmer than the warmest part of this country, but at Biarritz the weather was more spring-like still, the mean maximum temperature being 61° and the mean minimum 46°. On no less than 17 days the thermometer in the shade rose to 60° or above, and occasionally touched 70°, while on the 28th it recorded the summer figure of 77°. Biarritz and its vicinity was, in fact, much warmer than and generally as bright as the Riviera and experienced less rain. At Paris the sunshine amounted to as many as 71 hours, nearly three times that at Westminster, and the mean maximum temperature equalled 51½°. The nights were, however, colder than in London, the mean minimum temperature being 37°. In Central Europe the frost of the early part of the month was more intense and continued longer than in these islands. Readings below zero Fahrenheit were common, while the maximum warmth of the days was below 20°. In Germany the lowest minimum appears to have been 9° below zero Fahrenheit at Munich.

HYPERTRICHOSIS AND SPINA BIFIDA OCCULTA.

IN the last number of the *Deutsche Zeitschrift für Nervenheilkunde* is an article by Dr. Erich Ebstein, of the Medical Clinic in Leipzig, on the occurrence of hypertrichosis in association with spina bifida occulta. The first of the two cases he describes was that of a young woman, aged 16, suffering from chlorosis. On examination it was found that over an area of the back corresponding to the third, fourth, and fifth lumbar vertebræ there was a lozenge- or diamond-shaped patch of long fair hair, which had been present since birth, and had often been cut. There was no abnormal pigmentation of the skin. No central nervous system symptoms were to be found. An X ray photograph, however, showed that the spinous processes of the first and second lumbar vertebræ were definitely bifid, while that of the third was displaced a little to one side. The second case concerned another young woman, aged 22, suffering from acute rheumatism. On examination there was found in the middle-line of the back, over the second dorsal vertebra, a patch of rather long dark hair. There was no reason to suppose that the condition had not existed from birth, though the patient was unable to give any account of it. No symptoms referable to the central nervous system were present. In this instance the radiographic picture was of considerable interest. The cervical spinal column, the ninth and remaining dorsal

[1] See THE LANCET, July 17th, 1909, p. 165.
[2] THE LANCET, Sept. 24th, 1910, p. 962.

vertebræ below, and the lumbar were all normal. The sacral canal, however, was patent in the lower three sacral vertebræ—an anomaly that has occasionally been noted in association with spina bifida occulta. In the dorsal vertebræ above the ninth there were noteworthy alterations. The intervertebral discs could not be clearly made out; the bodies of the vertebræ appeared to have ossified together, so that one could with difficulty be distinguished from another. The third to the eighth ribs, inclusive, on both sides, were unusually small and unusually close together. The spinous processes of these vertebræ could not be distinguished, while the transverse processes, specially on the right side, were remarkably thick. The first dorsal vertebra was considerably deformed. A number of cases of hypertrichosis and spina bifida occulta have been described. The anomaly must date back to an early period in intra-uterine life. In such cases radiographic examination furnishes indispensable aid. Not a few of the "freaks" who have at one time or another been exhibited in public have been cases belonging to this category. Dr. Ebstein refers to "the lady with the horse's mane," a Miss Bell Carter, of Kentucky, in whom an overgrowth of hair between the shoulders was associated with bifidity or rather incomplete union of the spinous processes of the second and third dorsal vertebræ. The reader who may be interested will find other instances in Gould and Pyle's "Curiosities of Medicine." One of the most curious cases of this kind, of which Dr. Ebstein appears to be unaware, was recorded by Sir William Gowers in the *Medico-Chirurgical Transactions*, Vol. XC., 1908. In his case the patient was a man, aged 41, with a unilateral growth of long hair over the cervical region, just to the right of the middle line. The area was triangular, its base corresponding to the middle line of the back. With this was associated motor paralysis of the right arm, and some analgesia corresponding in part to roots from the fourth cervical to the second dorsal. The diagnosis which Sir William Gowers made of congenital syringomyelia seems amply justified. There is no record, however, of an X ray examination in this instance. No imperfection of the cervical arches and spines could be felt.

THE OPTICAL CONVENTION.

THE scheme for holding an Optical Convention, which was launched a few months ago under the auspices of a privately formed committee, has now assumed something of a public character by the issue of a definite programme of work for the convention and a scheme for the bringing together of an exhibition of optical and allied instruments in June next. The promoters of this undertaking have received very strong support from the scientific world, and we observe with interest that an application which they made to the Board of Education for housing space for their exhibition received the support, among other distinguished men, of the President of the Royal Society, the President of the Royal Institution, the Astronomer Royal, and Lord Justice Fletcher Moulton. The Board of Education has acceded to this request, and the exhibition will be held in space to be provided in the buildings of the Science Museum at South Kensington. The committee, taking advantage of the powerful support which it has thus secured, is proposing to make an interesting new departure in connexion with the exhibition. It proposes to circularise the users of optical instruments throughout the United Kingdom, through the medium of the various scientific societies, with a view of promoting improvements in the design and manufacture of the optical instruments in present use. The scheme, as set out in a report now being circulated by the committee, is to obtain comments in the form of criticisms and suggestions from all and sundry whose practical working with such instruments enables them to contribute to the discussion on these points. The material so collected is to be submitted to a small and very highly qualified committee, who will consider, elaborate, and make public in the form of a report the substantial results of this inquiry. The scheme is an ambitious one and, so far as we are aware, represents an attempt at systematic coöperation between the men of science and the manufacturers in a mode and on a scale quite without precedent. It is difficult to say what may not be accomplished by this committee with the effective countenance of the Government on the one hand and of the leaders of scientific thought on the other hand. In the case of a body with less resources we should have thought the plan somewhat over bold, but the circumstances of the case make it reasonable to expect for the present committee success in its undertaking.

RUPTURE OF THE COMMON BILE-DUCT.

IN the *Australasian Medical Gazette* of Jan. 20th Dr. Owen F. Paget has reported a very rare result of being run over—rupture of the common bile-duct. A boy, aged 7 years, was run over by a "sulky" on March 14th, the wheel passing from the right anterior iliac spine towards the liver. When seen on April 4th he was jaundiced and emaciated. The abdomen was full of fluid, the respiration was embarrassed, and the temperature was normal. There was no bile in the stools. Aspiration was performed and three quarts of aseptic bile were removed from the abdomen. The temperature shot up to 103° F., but returned to normal in 24 hours. On April 8th the abdomen was opened by the usual vertical incision for bile-duct operations. The liver appeared to have been torn from its suspensory ligament and rotated forwards, its superior surface becoming anterior. Its anterior edge was flattened out like ribbon and was adherent to the transverse colon. The gall-bladder was adrift from the liver and hung by its duct. Bile was found to leak from a point in the common bile duct at the hepato-duodenal ligament. During attempts to dissect out the duct the patient's condition became so serious that the operation had to be finished. A large rubber tube containing gauze was therefore passed down to the region of the tear, and the abdomen was closed. The gall-bladder was attached by a suture to the liver so that it could easily be found at a second operation. From 10 to 12 ounces of bile were passed through the drainage tube in 24 hours, while none appeared in the stools. Thus a difficult problem had to be faced. A very emaciated child, with a pulse of 130, required a delicate operation—suture of the common bile duct or anastomosis of its proximal end into the duodenum. The severed ends had probably widely retracted. It was decided, if possible, to suture or anastomose the duct, and if not, to short-circuit the gall-bladder into the colon, by which it was thought that half the bile would enter the colon and that thus the alarming emaciation might be combated and the strength increased so that the tear could be sutured by a later operation. On April 26th a second operation was performed. The liver was found to have regained its normal position and was adherent to the diaphragm. The gall-bladder had again gone adrift and could not be found and there were many adhesions from drainage tracts. The gall-bladder was ultimately found adherent to the posterior surface of the liver. It was sutured to the colon and the abdomen was closed, a drainage-tube being inserted. The patient was removed from the table barely alive. No bile discharged into the intestine and that discharging through the wound became fœtid. The child appeared to be dying. The drainage-tube was removed and the sinus allowed to close with the idea that by increasing

the resistance to the escape of bile it might be made to flow into the intestine through the gall-bladder. On May 7th there were severe pains in the upper abdomen apparently due to peritonitis, and on the 8th the motions were coloured brown. Three days later the presence of bile was proved chemically. A week later no bile appeared in the wound and the colour of the motions was normal. The temperature varied from 101° F. to normal. Recovery ensued.

THE SURGERY OF THORACIC WOUNDS IMPLICATING THE DIAPHRAGM.

AT a meeting of the Société de Chirurgiens de Paris on Feb. 2nd, reported in the *Presse Médicale* of Feb. 14th, an account was given of a surgical feat which reflected great credit on the surgeon responsible for it, M. Lepoutre, of Lille. The case was one of thoracic injury; projecting from an open wound in the wall of the chest there was a loop of intestine which was perforated. M. Lepoutre repaired the intestinal lesion, cleaned the external parts, and attempted to return the loop of bowel to the abdominal cavity, but was prevented by the fact that it was firmly gripped by the edges of the diaphragmatic wound through which it had escaped. He opened the abdomen instead of enlarging the thoracic wound so as to assure himself of the condition of the organs beneath the diaphragm. He found these intact and sewed up the wound in the diaphragm, which was 4 cm. in length. The abdomen was drained, but the pleural wound was closed. The patient recovered. M. Rigollot-Simonnot, who reported the case on behalf of M. Lepoutre, gave an interesting review of the different operations which might be used in such cases, with the indications for each. In his opinion immediate laparotomy is indicated only in cases of gunshot wound of the thorax implicating the upper abdomen, in abdominal injuries involving the thorax from below upwards, and in cases displaying unmistakable evidence of abdominal complications. In other cases he favours the thoracic route of approach to the diaphragmatic wound. Drainage should be avoided as far as possible, and should never be applied to the pleural sac; if the thoracic route has been adopted the drainage should be carried out through the diaphragm but external to the pleural sac. He considers that in the immense majority of cases in which immediate thoracotomy has been performed a secondary laparotomy will be necessary, especially when the injury has been on the left side of the chest.

(1) THE EFFECTS OF CAFFEINE UPON THE GERMINATION AND GROWTH OF SEEDS; (2) THE PROTEINS OF RICE.

THE February number of the *Bio-Chemical Journal* contains two papers under the above headings in which the respective writers make some interesting observations. (1) Dr. Fred. Ransom finds that caffeine delays the germination of seeds to a marked extent. Although the list of seeds tested was comparatively short, the results he regards are so uniform that they can hardly be attributed to chance. In every case except one (nasturtium) the seeds which had been treated with caffeine were later in germinating than the tap-water controls, and in a great majority of cases fewer seeds germinated in the caffeine groups. In the course of growth the caffeine-treated seeds were at first relatively less vigorous than those from tap-water, and in many cases they remained so till the end of the experiment. In three caffeine groups no seeds germinated. In no instance except the nasturtium had the caffeine groups any advantage over the controls. Having regard to the fact that caffeine in dilute solution applied to muscle increases the response to stimulation it might be expected to stimulate germination and growth. On the contrary, Dr. Ransom's experiments show that caffeine in a 1 per cent. solution retards or even prevents the germination and growth of seeds, and so far there is no evidence to show therefore that caffeine, either alone or in combination with other substances, can act as a stimulant to plant life. The investigation is an interesting one in view of the occurrence of the alkaloid in certain plants, and we are glad to note that it is being continued. 2. In the second paper the notes of Mr. S. Kajiura's investigation on the proteins of rice are given. A knowledge of the composition of the proteins of rice is obviously important from an economic and hygienic point of view, especially in relation to beri-beri. It was found that the proteins of "white rice," as used for dietary purposes in Japan, consist only to the smallest extent of albumins and globulins. The amount of alcohol-soluble protein is practically negligible, an observation which distinguishes rice sharply from all other cereals hitherto investigated. The main protein of rice (oryzenin) belongs to the glutelin class—that is, proteins soluble in weak alkali. In its nitrogen cleavage it differs from wheat glutenin (the only other glutelin so far studied) very considerably. The results are suggestive, and will no doubt stimulate further work on this important subject.

Sir Anthony A. Bowlby, Surgeon-General Sir Arthur M. Branfoot, Sir James Kingston Fowler, Mr. George H. Makins, C.B., Dr. H. D. Rolleston, Mr. Charters J. Symonds, and Dr. James Taylor have been appointed to the consulting staff of the Convalescent Home for Officers at Osborne, Isle of Wight.

THE Council of the Royal Society has recommended for the Fellowship, among others, Professor Benjamin Moore, Mr. Edward Nettleship, Professor Robert Newstead, and Dr. William McDougall, all of whom have assisted by their scientific work in the direct progress of medicine.

THE King has conferred the honour of Knighthood upon Mr. W. M. A. Anderson, M.V.O., M.B. Durh., who as honorary surgeon to the Princess Royal was summoned to Egypt to attend to the late Duke of Fife.

WE regret to be compelled to delay publication this week of our report of the adjourned joint debate of the Medical, Surgical, and Anæsthetics Sections of the Royal Society of Medicine on Thyroidectomy.

THE King has appointed Mr. William Joseph Essery, M.B. Durh., M.R.C.S. Eng., to be a Commander of the Royal Victorian Order.

IT is in contemplation that a life of Lord Lister should be prepared. Any letters of scientific interest forwarded to Mr. R. J. Godlee, 19, Wimpole-street, London, W., will be gratefully received, and returned after copying if desired.

Dr. StClair Thomson has been unanimously elected a Corresponding Member of the Wiener Laryngologische Gesellschaft.

MANCHESTER UNIVERSITY SETTLEMENT.—A conference will be held at the Settlement, Ancoats Hall, Every-street, on Thursday, March 21st, at 7.30 P.M., on School Clinics, when papers will be read by Dr. Lewis A. Williams, medical superintendent of the Bradford education committee, and Mr. William H. Jones, the borough dentist at Cambridge. The papers will be followed by discussion.

THE PROBLEM OF AFTER-CARE OF SANATORIUM PATIENTS.[1]

BY T. D. LISTER, M.D. LOND., M.R.C.P. LOND., F.R.C.S. ENG.,

PHYSICIAN TO THE MOUNT VERNON HOSPITAL FOR DISEASES OF THE CHEST, AND ADVISORY PHYSICIAN TO THE NATIONAL SANATORIUM ASSOCIATION.

THE treatment of consumption is a costly matter. It is only the still greater cost to the community of the disease itself that justifies the many ways of spending money on treatment that have their several advocates. Among these the sanatcrium has the pre-eminence of being the most costly, and of having the greatest number of skilled supporters. The sanatorium has come to stay, whatever the advocates of other methods may say in its disparagement, or as to the advantages of their own schemes in comparison. It is not necessary here to enter, save incidentally, into the question of the relative value of the alternatives to the sanatorium. Wherever tuberculosis is being fought sanatoriums are established. The sanatorium is recognised as an essential link in the chain of measures which the hygienists of all civilised countries are beginning to adopt. I say beginning, because as yet we are but at the threshold of the struggle. For the causes of the disease are still scientifically unknown.

The Problem of Relative Immunity.

We know certain things. We dogmatise upon them. But our dogmas are open to all forms of criticism. It is needless for me to tell you that the discovery which placed Koch among the immortals is the basis of all our present-day work. The tubercle bacillus is the infective agent, and all cases of consumption are due to the invasion of the body by this microbe. We recognise certain conditions of the body which render it vulnerable, some inherited—this for the eugenists—and some acquired—this for the immunists and sociologists.

But what is this vulnerability? Why is A apparently resistant to the ubiquitous infection and B an easy prey? In what essential qualities do their bodies differ? In what lies the difference between the tissues of the patient who dies in a few weeks from "galloping consumption" even when surrounded by everything that should make the onslaught of the bacillus difficult, and those of the patient badly fed and housed who goes on for 10 or 20 years fighting an indecisive battle, but able all the time to earn a living? Why is there every degree of ability to "stand" a dose of infection?

It is this very difficult question of relative immunity, full of all the problems of pathology, that leaves us, and I fear will leave us for years to come, in no position to answer it. The real answer might give us the clue to the real treatment.

What is being Done?

Meanwhile, what are we doing? We are taking refuge in the teachings of hygiene. We know that certain conditions of living, to which the sanatorium presents the antithesis, are associated with a high rate of attack by consumption of those who live under them.

We say, let us give to as many as possible of these those hygienic conditions they have lacked. Let us adopt the political maxim, "The greatest good of the greatest number," and apply it to the attempt to cure consumption.

I have no delusions as to the statistics of sanatorium results. We have, as has been pointed out, no strictly comparable figures of the results of sanatorium treatment and of non-sanatorium treatment. What has been said of sanatoriums is, to my mind, equally true of other methods of treatment, but I will not venture to go into that.

Teachings of Hygiene.

At present the hygienists of the world are agreed as to the conditions of living which produce liability to the disease. They are also agreed as to the value of the sanatorium in producing resistance to the disease.

The sanatorium, like consumption itself, is a product of civilisation. For good, or for ill, we herd masses of our populations in cities and cage them in factories and tenements. Hygiene, by constant watchfulness, enables us to make the best of things according to the means at its disposal. So far as consumption is concerned, it points out the dangers of infection and the evils of dirt, overcrowding, overwork, under-feeding, drink, and heredity in encouraging infection. It says, if we could only take all the infectious cases away, and if we could destroy the conditions which encourage infection, we could stamp out this plague. Meanwhile, it says also, let us take the case that is as yet still only invaded, and not effectively occupied by the enemy, and give it healthy conditions. Let us supply those weapons of fresh air, cleanliness, sunlight, rest, food, exercise, and sobriety—which are known to be necessary for the body to beat back or surround, perhaps to destroy, the invader.

That the sanatorium does provide such weapons may be accepted. But the individual resistance of the patient—his relative immunity—is an unknown factor, and so statistical experts riddle the results of sanatorium treatment with criticism, while unable to tell us what better to do.

The Sanatorium a School of Hygienic Living.

I say let us be content with teaching the lessons of hygiene. Whether our results be 50 per cent., 60 per cent., or 80 per cent. of arrested cases is immaterial, so long as we train the ignorant dangerous consumptive into ways of safety.

Elsewhere, on another occasion, I have said that this battle against consumption is one of the problems of industrial disease.[2] I said that the sanatorium is only a link in the chain of measures necessary. But it is the one great object lesson in the prevention and treatment of consumption. It is the school of hygienic living for the consumptive. Since my attention was specially directed to tuberculosis I have always recognised this. For a paper, written jointly, and published some years ago in THE LANCET,[3] I suggested the title "A National School for Consumptives." The views that I then advocated, and have consistently insisted upon on the Council of the National Sanatorium Association and elsewhere, are now likely to be adopted as a State provision. The scheme of an industrial sanatorium that I drafted in 1903–1904, which has now been for five years successfully carried out at Benenden, was framed with educational objects in the forefront, as well as those of economy in construction and administration. So far as education goes a sanatorium is a necessity. We might as well say that the bulk of children can be taught as well at home as at school, as that the mass of consumptives can be treated as well at home as in an institution.

Limitations of the Sanatorium.

But I have always pointed out very clearly that the sanatorium has great limitations. It is not enough to "select early cases," as the phrase goes, to send them away to sanatoriums, to let them receive their training for as long as thought fit, and to send them back again "cured," as distinguished laymen hope, to all the evils from which we have only rescued them for a few short months. I pointed out that though much can be done by such methods, yet still more remains to be done, not only in the treatment but in the prevention of the disease, which includes the prevention of relapses. The far greater problem remains.

It may be easy to "cure" or to "arrest" certain early cases, if we select those who can "stand" a dose of infection fairly well. But who believes that any large proportion of such arrested cases will remain well without after-care? Does anyone believe that a person who has once lost that undefined quality of immunity to tuberculosis, and who has now apparently regained it by sanatorium methods—or any methods—is a better life for resisting a fresh attack than one who has never had the disease? Will any insurance office bet the average odds against the chance of such a person dying from consumption?

Combination of all Methods of Treatment Needed.

There is something—there are many things—we do not know about the pathology of the victims of tuberculosis, but one we do know is that the consumptive class is consumptive.

Of course, I am not ignoring the many sanatorium cases that stay well for years after leaving off treatment, nor the cases treated by tuberculin or any other method that do the same. But are not such cases originally resistant? Were not the symptoms which led to their treatment merely the evidence of a diminution of resistance due to some transient

[1] An address delivered during the exhibition at the Royal Sanitary Institute on Jan. 19th, 1912.

[2] "Industrial Tuberculosis," T. D. Lister, THE LANCET, Oct. 15th, 1910.

[3] Garland and Lister: THE LANCET, March 9th, 1907, p. 677.

disturbing cause? The infection is everywhere. So large a proportion of the general population has tuberculosis and are able to get well of it, as shown by many pathologists, that it is not surprising that many such cases pass through the hands of the sanatorium doctor or the physician who immunises by the direct administration of tuberculin. Their disease is only a ripple on the calm sea of health.

Such cases afford, I am convinced, a large number of our most successful results. In other words, the more solid the foundation of natural tolerance, or natural resistance, on which our treatment is superadded, the more lasting will be the superstructure of health.

You will, I trust, forgive me for having thus entered on debatable matters, but I have spoken with no desire to do aught than suggest one of the factors that I think should not be lost sight of in the after-care problem—namely, the relative immunity or resistance of individuals.

By "careful selection" of cases anyone can get good results in a large number of cases of infection by tubercle. But until "careful selection" can be replaced in our medical phraseology by something which leaves less to the personal view of the doctor who uses the term, we must rely for our treatment of consumption among the people on a combination of all the methods of all the doctors. Let us remember that patients are patients and not a row of bottles. We must not waste time and energy in disputes as to whose method is best, but use every method in turn for the cases it suits best.

Part Played by the Sanatorium.

No national system of insurance will enable us to detect latent tuberculosis in the enormous number of people who must have got it, and who are unconscious of it. It is even difficult in the present state of medical education to secure early diagnosis of many who apply for treatment for slight vague illness, as to their possibly being affected by active tuberculosis. Most of the cases admitted to sanatoriums are, and will continue to be, people who are really ill. People who are not ill will not apply.

Let us agree to-day that the sanatorium does, and will continue to do, its part in restoring some of these people to apparent health, and that it teaches many others the ways of health. Some of the first class will remain well for reasons I have stated, others will relapse and seek readmission, others will relapse and die. Some of the second class will learn their lesson so thoroughly that, aided by their own resistance, they will gradually progress to health, others will become chronic, others relapse, and others will die.

It is a pessimistic outlook for those who do not profit by the teaching of the sanatorium, or who are unable to practise after they leave what has been demonstrated and preached to them.

After the Patient Leaves the Sanatorium.

No sanatorium alone cures consumption. Much more is necessary than the three or four months of treatment in a sanatorium. If immunity in our most successful cases has for a time been lost, it has been lost with difficulty, and the foundation of natural resistance must be there or they would not be successful. Will it be regained easily? I think not. The hygienic conditions of sanatorium life will do good as long as they last. But for the permanent recovery of immunity the invaded territory must be again rendered untenable by the enemy.

After leaving the sanatorium the lessons it teaches must be taken into the home and the workshop, into the daily life and habits of the consumptive, for years to come. Sanatorium treatment is not merely putting patients in an open-air shelter, nor resting and exercising them against a temperature chart, nor stuffing them like pigs against a weight record, nor establishing a tolerance of tuberculin injections. These things it is the province of the physician in charge to effect. As a result the patient may leave the institution apparently well. But sanatorium treatment to be effective must have induced something else. It must have roused the patient to the fact that all this machinery of detail meant something vitally important to him—to him himself. He must leave determined to remain well; he must be inspired to imitate the sanatorium life as a necessity of his future existence, and the machinery for so doing must be set up.

This is the problem of the after-care of sanatorium patients—to inspire the patient and to give him guidance and help. How difficult it is for the vast mass of consumptives the increasing literature on the subject affords abundant proof. Every physician who studies this disease is faced by the problem every day. If it is difficult in the case of the patient discharged as "arrested," how much greater is the difficulty in the case of the patient who is discharged only on the way to health or worse.

The Social Problem.

The social problem involved is second only to the strictly medical problem. So well has the lesson of the infectivity of tuberculosis been taught, that the patient is often faced on his return to work by the aversion of his former colleagues. His employer may even be compelled to refuse to restore him, or a new employer to refuse to engage him, quite apart from the employer's risk of legal liabilities.

The public does not grasp the necessary qualifications of a scientific fact easily. The untrained infectious workman with chronic consumption, which does not in his opinion require treatment, is often tolerated while he distributes his spit everywhere, but the returned safe sanatorium patient is boycotted. Moreover, the working conditions under which the patient could previously earn a living may have been the very cause of the loss of resistance which led to his disease declaring itself.[4]

The Question of Change of Occupation.

Idealists have suggested the abandonment of the old life and the taking on of a new means of livelihood. Such a course is impossible for the great mass of consumptive workers. Not until England is again an agricultural country would this be possible here, and, as someone has truly said of "farm colonies," "You cannot make a consumptive clerk or drunken docker into an efficient agricultural labourer;" it is economically impossible.

Our overseas colonies have their various climatic advantages and disadvantages. But the colonies are not opening their arms to receive weaklings. The consumptive class is consumptive, and nobody wants them. Individual instances of brilliant recoveries under colonial conditions are familiar to us, but no protest can be too strongly worded against the loose prescription, "Take a voyage to Australia."

Changes of occupation from clerkship to land surveying, from indoor book-keeping to outdoor agency, and so forth are sometimes possible. But as a rule the patient whose resistance has apparently been restored by a stay in a sanatorium must depend upon himself, and continue in the same employment as before he broke down.

Unfavourable Cases.

For those who only just hold their own under sanatorium conditions a return to their employment means disaster. For those whose resistance was unequal to any attack, and who are gradually going down hill, after-care means the provision of an easy death-bed if possible.

The Government will have some better plan, let us hope, than the infirmary ward for the dying industrial consumptive. For those to whom ordinary city life is impossible provision should be made in model health villages or colonies, but they will be almost inevitably State pensioners. Afforestation schemes, farm colonies, outdoor official positions, and many other suggestions have been made for dealing with various groups of these cases, and we must do what we can for them—a phrase which often signifies our inability to do anything.

"Arrested" Cases.

But the case of the first class, the "arrested" case, is the one to which most attention as regards "after-care" is being paid. It was, no doubt, this class of case which was in the mind of the council when this exhibition was arranged. What is the position of the man who leaves the sanatorium labelled "arrested," "fit for work," "able to do a good day's work without any reaction"? *He is a person threatened by consumption* as much as he was before symptoms of illness led him to make his first appearance before a doctor—but he knows more. It is on his own personal enthusiasm and discretion, as well as upon the unknown factor of his natural resistance, that the permanence of his cure will depend. He can continue his treatment according to his opportunities. The backyard shelter, the canvas pavilion, the regular, sober life that he has learned to live—all the machinery of which he has acquired experience will be of use to him. But he is still threatened

[4] Loc. cit. ("Industrial Tuberculosis.")

with consumption. The tuberculosis dispensary, the tuberculin dispensary, the hospital, the infirmary, the farm colony, our overseas colonies, and the patient's backyard all have their place in the after-care problem. So we see that the after-care problem is not different from, but identical with, the problem of the prevention of consumption, with the one great difference that the patient is educated.

The Prevention of Consumption.

It is bad conditions massed under the term "environment" which produce loss of resistance, and infection which excites the disease. All our energies must be directed in the way of prevention. We cannot at present deal with the existing conditions of life among those most susceptible. Hygiene must be preached not only to those interested, but to those who are not interested. The health conscience of the people must be aroused or created.

As success in sanatorium treatment depends on the inspiration of the patient, so success in the prevention of consumption must depend upon the inspiration of the poorest and most ignorant classes of the people. Health teaching must find its way into our schools and homes. We must secure as wholesome a condition in the workshop, office, and dwelling as exists in the coal-mine or inspected factory. We must provide proper food and recreation, and implant a desire for higher ideals among the masses.

If we succeed in a campaign of prevention, the problem of after-care ceases to exist. It is this problem of prevention, which I say includes after-care, that is the real question for solution by the statesmen whose care is that of the public health.

CRAWFORD WILLIAMSON LONG, THE PIONEER OF ANÆSTHESIA.[1]

BY DUDLEY W. BUXTON, M.D., B.S., M.R.C.P.,
ANÆSTHETIST TO UNIVERSITY COLLEGE HOSPITAL AND LECTURER ON ANÆSTHETICS IN UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

Crawford Williamson Long was the pioneer of anæsthesia and the first to suggest and employ ether inhalation during surgical operations. Although the discovery of anæsthetics has bestowed the greatest blessing upon suffering humanity its birth has been marked by much polemic and in some cases with scant recognition of those who have done so much for mankind. While disputants claiming for themselves, or their friends, the plaudits due to great discoverers have rent the welkin with their angry cries and clamoured for a material solatium, one man, Crawford Williamson Long, reputed to be actually the first to produce artificial anæsthesia by inhalation of ether, was content to stand aside, calm and dignified, as one who strove to benefit his race while seeking for himself neither guerdon nor worldly honour. I propose to submit to your consideration the facts which have been accumulated and which, to my mind, prove Long's right to the world's acknowledgment that he was the pioneer of anæsthesia.

Views on Possibility of Anæsthesia at the Time.

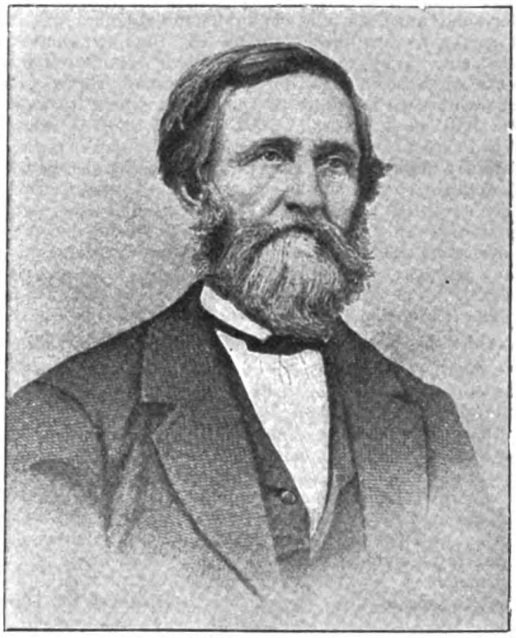
It is impossible to do justice to the man without making at least an attempt to understand the environment in which he worked, and to analyse the professional and public opinion at the time he lived concerning the possibility of anæsthesia. Even so late as 1846 Sir Benjamin Brodie wrote: "Physicians and surgeons have been looking in vain, from the days of Hippocrates down to the present time, for the means of allaying or preventing bodily pain." In his mind were, no doubt, the spongia somnifera of Theodoricus of Lucca, opium, cannabis indica, mandragora, and the whole gamut of nostrums vaunted through the centuries; the claims of Denis Papin, and of Cardan, whose magnet he averred could abrogate pain; the compression of the carotid arteries by Valverdi; nerve compression, suggested by Ambroise Paré and practised by James Moore, and subsequently by John Hunter in St. George's Hospital; Wardrop's (1832) bleeding to syncope, adopted by Richerand; and Mesmer's claims to dissociate the astral from the corporeal body. Many methods had been called, but, as the sequel will show, few had been chosen.

[1] A paper read before the Section of Anæsthetics, Royal Society of Medicine, Dec. 1st, 1911.

Some Biographical Details.

But what of the man himself? Crawford Williamson Long was born on Nov. 3rd, 1815, at Danielsberg, Georgia. (Fig. 1.) His people were of high intellectual and social standing; his grandfather, Captain Samuel Long, who had emigrated from Ireland, was a philanthropist and man of affairs, prominent in the war of his troublous times. Captain Long's wife was a Miss Williamson, of Ulster, and her maiden name was perpetuated in that of her grandson. Of Long's father we learn that he was high in the esteem of his fellow-countrymen and the intimate friend of W. H. Crawford, after whom he named the subject of this history. Crawford held important official posts, twice represented his country in France, and was a Secretary of State. Long's mother, although an invalid, by her literary gifts added culture to her home. Thus was Crawford Long brought up amidst

FIG. 1.



Crawford Williamson Long, M.D.

refined and public-spirited persons, an environment which could but make for those traits of character which in later life developed him into the best type of the man and of the physician.

A few words will suffice to tell the subsequent story. "Studious and wise beyond his years," Long, whose extreme youth when he went to college earned him the *sobriquet* of "The Baby," graduated brilliantly at Franklin College—now the University of Georgia—when but 19 years old. His chief friend and class-mate was Alexander H. Stephens, later to be elected Vice-President of the Southern Confederacy, and to him and Long have been erected monuments in Statuary Hall, Washington, the twain chosen by Georgia as the greatest men of her State. Thence he proceeded to the University of Pennsylvania, and at the age of 23 graduated in medicine. As was customary for those who could afford it, Long spent some time after this in walking the hospitals of New York. The suggestion made to him by his teachers, who recognised his peculiar merit as a surgeon, that he should attach himself to the medical service of the United States Navy, was discountenanced by Long's father, and at the latter's instance he settled as a general practitioner in Jefferson, Georgia, and commenced civil practice in 1841 at the age of 26.

Operations on Hypnotised Patients.

It should be remembered that it was in this same year that Braid, of Manchester, made his trial of the "neurhypnotic trance," and Esdaile in India successfully operated upon hynotised patients. Elliotson, who had migrated from St. Thomas's to University College Hospital, was then giving the full weight of his great mental power to

mesmerism, although his book on "Surgical Operations Performed in the Mesmeric State without Pain" was not published until 1843. There is no doubt that at the time of which we write mesmerism, or the hypnotic trance, was regarded as the accomplished fact of anæsthesia, and that in the United States many of the leading men in medicine and surgery accepted it as the long-hoped-for panacea whereby suffering humanity could pass unflinchingly through the ordeal of the surgeon's knife. In France, Richerand had tried it and pronounced for its value, and other surgeons scarcely less eminent were willing to swallow the doubtful reputation of Anton Mesmer so long as they could benefit their patients by employing methods which had been exploited by his fertile brain.

Inhalational anæsthesia thus started with a heavy handicap. In 1846, to anticipate, the editors of the *New Orleans Medical and Surgical Journal* wrote, *apropos* of ether inhalations: "That the leading surgeons of Boston could be captivated by such an invention as this under such auspices and upon such evidences of utility and safety as are presented by Dr. Bigelow excites our amazement. Why, mesmerism, which is repudiated by the *savants* of Boston, has done a thousand times greater wonders and without any of the dangers here threatened. What shall we see next?" *En passant*, let it be remarked that the sapient editors were condemned to see many things apparently unpalatable. But putting this aside, the quotation appears to show that the utility of mesmerism was widely accepted and constantly practised during surgical operations, even if the Bostonian *savants* condemned it; and further, that any fresh departure in the direction of promoting painless surgery was open to the most embittered criticism. The importance of this fact will be made manifest in the sequel of our narrative.

Knowledge then Current about Ether and Nitrous Oxide Gas.

We must, however, retrace our steps for a brief space and try to obtain a clear idea of what was the current knowledge about ether before Long's first trials of its powers as an anæsthetic. In the books dealing with drugs and poisons ether found a place. It had been known since the thirteenth century, and although some of its merits were recognised it was regarded as so dangerous as to be taboo. However, when, through the enthusiasm of Dr. Beddoes, the work of Priestley, and the discovery of oxygen and nitrous oxide, pneumatic medicine became a vogue ether again assumed prominence.

The foundation of the Hotwells Hospital at Clifton, Bristol, by Dr. Beddoes gave that astute physician a wide experience in inhalational medication. He had studied Mayou's experiments and was familiar with Priestley's work, so that when young Humphry Davy, freed from his indentures to a doctor in Penzance, became his assistant, Beddoes was able to study the gases, the effects of which in the treatment of disease he has given in his delightful collected writings in four volumes. Of the volume entitled "Considerations on the Medicinal Use and on the Production of Factitious Airs," the first part was Beddoes's work, the second being due to James Watt, the engineer. In one of these volumes we find a letter from Dr. Pearson, of Birmingham, the accepted authority in his day upon therapeusis both in this country and in the States. In it he says that Beddoes's researches on "Factitious Airs" had led him to try "the vapour of ether" to relieve the suffering of phthisical patients and with benefit to them. Further, when Mitchell's book on chemistry appeared Beddoes found to his chagrin that the chemist declared nitrous oxide to be a "virulent poison," so he recommenced experiments with oxygen and nitrogen as well as with nitrous oxide gas. Davy, who undertook these researches, came to the conclusion that Mitchell was wrong, and that "the gaseous oxide of azote is perfectly expirable (*sic*)." He also announced that its inhalation cured the pain of an aching tooth, and added: "It may probably be used with advantage during surgical operations in which no great effusion of blood takes place." Alas, no one took the hint, and nitrous oxide remained for nearly 50 years the chief stock-in-trade of travelling lecturers, who gave this gas to members of their audience to provoke exhilaration and semi-unconscious gyrations. These "frolics" were well known, and M. Filvée, in his "Lettres sur l'Angleterre" (1802),[2] mentions these revels as one of the many follies to which English people were prone.

These practices became also common in the States, and it will be remembered it was at one of them that Horace Wells was present when he conceived the idea of using the gas as an anæsthetic. This, of course, happened much later, in 1844. But nitrous oxide gas needs a plant for its accurate manufacture, so that Pearson's suggestion of employing ether vapour as an exhilarant found ready acceptance. Cullen, whose works were read widely both here and in America, advocated ether, and Warren, of Boston, extolled its use in place of nitrous oxide. We see then that in 1841, when Long commenced practice, it was common knowledge that nitrous oxide produced exhilaration, but the suggestion of its employment as an anæsthetic by Davy was forgotten; ether was recognised as producing similar effects, but if we except the doubtful hint in the *Journal of Sciences and Arts* associated with the name of Faraday (1818), no one had grasped its greater merits, while the books of Pereira and others cautioned against its employment, since stupor and death they averred might readily be brought about. Long, it appears, had when a student actually inhaled ether during an "ether frolic," and was so far familiar with its effects.

Long's Early Experiments.

Jefferson in those days was an isolated country village—one might almost say, "the world forgetting, by the world forgot"—so that Long had to pursue his own way relying upon himself and practically out of touch with the centres of surgical thought. His personal charm and high scientific attainments made his house a place of social resort for the neighbourhood. Let Long himself tell us of the fateful happenings of December, 1841. He says:—

> In the month of December, 1841, or January, 1842, the subject of the inhalation of nitrous oxide gas was introduced in a company of young men in this village (Jefferson), and several persons present desired me to produce some for their use. I informed them that I had no apparatus for preparing or preserving the gas, but that I had a medicine (sulphuric ether) which would produce equally exhilarating effects: that I had inhaled it myself, and considered it as safe as the nitrous oxide gas. One of the company stated that he had inhaled ether while at school, and was then willing to inhale it. The company were all anxious to witness its effects. The ether was introduced. I gave it first to the gentleman who had previously inhaled it, then inhaled it myself, and afterwards gave it to all persons present. They were so much pleased with the exhilarating effects of ether that they afterwards inhaled it frequently, and induced others to do so, and its inhalation soon became fashionable in this country, and in fact extended from this place through several counties in this part of Georgia.
>
> On numerous occasions I have inhaled ether for its exhilarating properties, and would frequently, at some short time subsequent to its inhalation, discover bruises or painful spots on my person, which I had no recollection of causing, and which I felt satisfied were received while under the influences of ether. I noticed my friends while etherised, received falls and bangs, which I believed were sufficient to produce pain on a person not in a state of anæsthesia, and on questioning them they uniformly assured me that they did not feel the least pain from these accidents. These facts are mentioned that the reasons may be apparent why I was induced to make an experiment in etherisation.

First Operation under Ether Anæsthesia.

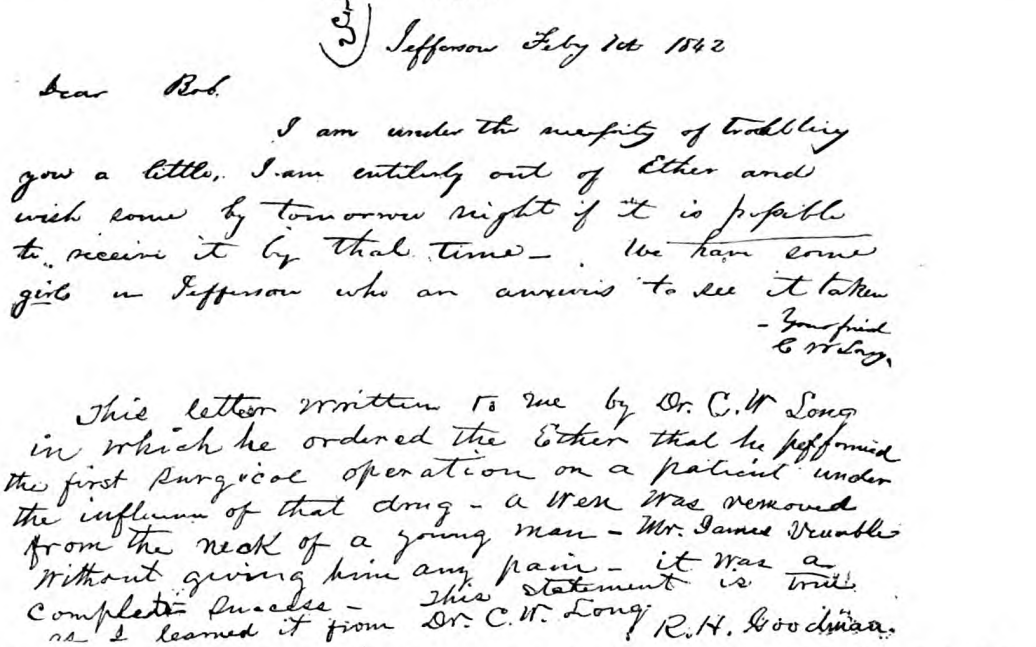
The first trial of his theory was made on March 30th, 1842, and the narrative is given in Long's published account of his experiments. James M. Venable was etherised by Long, who poured ether upon a towel, and when the patient was profoundly unconscious he removed a cyst from the back of the patient's neck. No pain was felt. This was four and a half years before Morton's first case. Subsequently Long used ether on several occasions, eight it is said, and every case was successful. That he did not employ it more largely was due firstly to the fact that his practice was one in which operations were seldom demanded, and secondly because the older practitioners around him urged upon him the "danger" of the method and the disastrous results which would follow a fatal accident, such an accident as they were good enough to say must soon occur. Indeed, Long was more than once threatened with pains and penalties by the community in which he lived if he persisted in his ether practices!

Reason of Long's Silence.

Now, although Long did not conceal his work, for it was known widely in the neighbourhood, as is shown by the facsimile letter which is here reproduced (Fig. 3), he took no occasion until later to read a paper before a medical society dealing with his experiments. This silence has been misconstrued. The simplest justice, however, must explain Long's reticence in a sense which redounds wholly to his credit. Long believed in his method, but recognised that it needed careful working out; he patiently experimented when patients seemed suitable; when they were

[2] Quoted by Mr. George Foy ("Janus") in his life of C. W. Long, 1900, p. 2.

FIG. 2.



Jefferson Feby 1st 1842

Dear Bob.

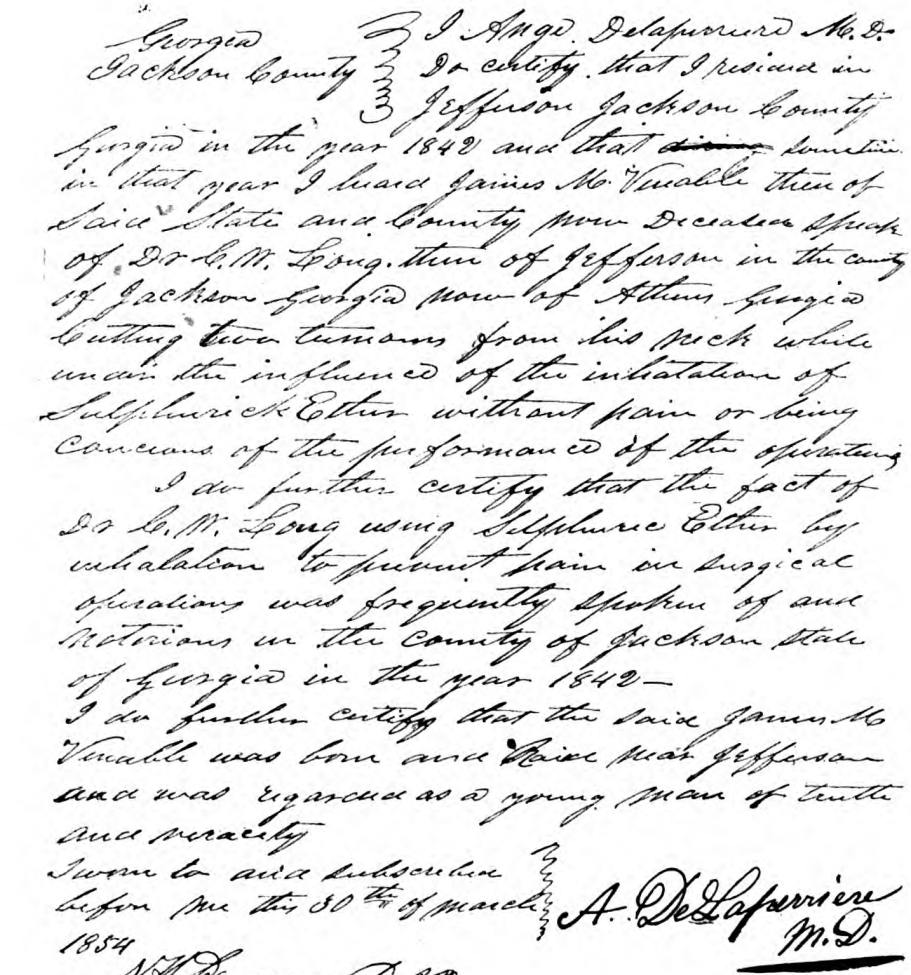
I am under the necessity of troubling you a little. I am entirely out of Ether and wish some by tomorrow night if it is possible to receive it by that time. We have some girls in Jefferson who are anxious to see it taken

Your friend
C W Long.

This letter written to me by Dr. C. W. Long in which he ordered the Ether that he performed the first Surgical operation on a patient under the influence of that drug - a tumor was removed from the neck of a young man - Mr. James Venable without giving him any pain - it was a complete success - This statement is true as I learned it from Dr. C. W. Long R. H. Goodman.

The facsimile letter written in 1842 by C. W. Long to Mr. R. H. Goodman, and a note written upon the enfold of the letter by the hand of R. H. Goodman. The ether was used for an "ether frolic" and for the first operation upon J. M. Venable.

FIG. 3.



Georgia
Jackson County

I Augt. Delaperriere M.D. do certify that I resided in Jefferson Jackson County Georgia in the year 1842 and that ~~since~~ sometime in that year I heard James M. Venable then of said State and County now Deceased speak of Dr C. W. Long then of Jefferson in the county of Jackson Georgia now of Athens Georgia Cutting two tumors from his neck while under the influence of the inhalation of Sulphuric Ether without pain or being Conscious of the performance of the operation

I do further certify that the fact of Dr C. W. Long using Sulphuric Ether by inhalation to prevent pain in Surgical Operations was frequently spoken of and Notorious in the County of Jackson State of Georgia in the year 1842—

I do further certify that the said James M. Venable was born and Raised near Jefferson and was regarded as a young man of truth and veracity

Sworn to and subscribed before me this 30th of March 1854

N. H. Pendergrass J.P. [illegible]

A. DeLaperriere M.D.

not available he tried it on himself and on his pupils. He knew that the public were in favour of mesmerism, a system which he regarded with disfavour, and he had no surgeon of eminence in his neighbourhood to whom he could apply for extended experience. The doctors who knew of his efforts were adverse to them, and so he preferred to wait and gain experience before attempting to exploit a discovery which might have less in it than appeared at first sight. He was alive to the fact that some might believe they found in his practice a development of hypnotism, an anæsthesia by suggestion. But while he waited events were happening in the bigger world of which Long recked nothing.

Morton and "Letheon."

Horace Wells had "discovered" nitrous oxide gas, had tried it and been successful in Hartford, Connecticut, 1844. His essay before the surgical world in the General Hospital, Massachusetts, had been a fiasco; he (Wells) had been shrieked out of the theatre with cries of "humbug." With or without the aid of Dr. Jackson, a man of scientific attainments and State geologist and chemist, Morton had administered ether vapour to himself, subsequently to one or two patients, and ultimately had been permitted by Warren, the surgeon, to administer his nostrum to a patient in the "General Hospital." "This, gentlemen," Warren had said, "is no humbug": anæsthesia by inhalation was an accepted fact.

These events occurred in 1846, but sadly enough the "ether controversy," which embroiled Morton, Jackson and Wells, involves much that we would rather not dwell upon, since the details are far from pleasant reading. We must, however, refer to some points since they connect the story with that of Crawford Long. We spoke of Morton using a "nostrum"; it was sulphuric ether with flavouring additions, and was termed "Letheon." Its identity with ether was challenged, and eventually the medical profession refused to allow further public trials without a disclosure of its nature and composition. The attempt was made to protect letheon by a patent, and to restrict its employment unless a royalty was paid. An English patent was actually granted. W. T. G. Morton was not a medical man, and probably saw no objection to reaping a golden harvest from what he no doubt honestly believed to be his discovery. This restriction on the use of letheon has been denied, but the letter of Dr. Charles A. Davis appears to substantiate the fact.[3]

We know the sequel; the world awoke to the anæsthetic value of ether. There can be no question that whatever motives actuated him Morton's public exhibitions of ether in an important surgical centre were the direct means of publishing the discovery to all civilised communities. Failing to support the rights which he fondly hoped would protect his patent of letheon, Morton sought to secure a grant from Congress, and to be proclaimed the discoverer of ether, and the first to apply it for the purposes of anæsthesia. Dr. Jackson advanced that he had a prior right, asserting that he had suggested the use of ether to Morton, and that the latter's employment of it was at his (Jackson's) instance. Into the merits of this controversy we need not enter, since both Morton and Jackson had been anticipated by Long.

The reasons why Long did not publish his first cases have been pointed out already. However, when Morton's success was bruited about, the duty of making a statement concerning his own cases was brought home to Long, and he put himself into communication with the editor of the *Southern Medical and Surgical Journal*. In 1849 we find in the columns of that journal the following: "A few months ago Dr. Long informed us of his early attempts at etherisation in surgery. He was then informed that any claims set up at this late day to priority of discovery would be severely criticised, if not violently resisted; and that he had best, therefore, do all he could to fortify his position."

Long, in his communication to the Medical Society of Georgia (December, 1849), explains that so soon as he saw from the current medical literature (1846) that letheon had been successfully used, he actually commenced a paper for publication detailing his own experiences with sulphuric ether. Unhappily, the exigencies of his practice intervened and the paper was never completed.

The Rival Claims.

In 1849 Morton petitioned Congress for a monetary reward for his discovery, and his claim was opposed by Jackson and Wells. In 1854, after much persuasion, Long was induced to write to Senator Dawson detailing his own work. The Senator sent Dr. Jackson a curious choice when it is remembered that that gentleman was one of those who claimed the laurels of having discovered ether. The interview took place at Athens, Georgia, to which town Dr. Long had removed in 1851, and Long told his story simply but so effectively as to convince Jackson of its truth.[4] The matter was ventilated in Congress by Senator Dawson, and although Morton's petition was never granted, yet to Crawford Long no recognition was vouchsafed. It is significant that Dr. Jackson urged upon Long that they, Jackson and Long, should unite interests, and as partners claim that they had respectively discovered the use of ether as an anæsthetic, and actually essayed experiments and successfully proved the safety and value of the method. Long was not tempted; he declined in words of striking dignity. He writes: "Our claims are rival, and permit me, sir, to say that although our claims are conflicting, I would not knowingly say anything in the article [he was preparing a full statement of his work in the form of an article] which would be displeasing to you. ..... Still, it becomes each one of us to use all honourable means to advance his own claims, and I know you will not blame me for attending to this matter, which so much concerns my reputation." So the matter dropped, and men forgot Long or minimised his work, and on Ether Day celebrations to Morton is accorded the palm. In 1877 Dr. Marion Sims championed Long's cause, but, unfortunately, his communication so well conceived was hurriedly executed and introduced the inaccurate statement that S. C. Wilhite had suggested to Long the idea of using ether. Wilhite himself contradicted this, and his letter is extant. As a matter of fact, he did not come to live with Long as a student until 1844.

Close of the Story of Long's Life.

So we come to the close of the story of Long and his great discovery, the story of a simple-minded man who, amidst the arduous labours of a scattered country practice, conceived a great idea and, in the teeth of opposition, and though haunted by the fear lest disaster might arise and ruin his professional name and reputation, yet had the courage to test his theory by experiment, and so obtained proof of its accuracy. Surely such a man was worthy to be the author of so momentous a discovery, and of being called one of the greatest men brought forth by a mighty nation.

A few words will suffice to trace the closing years of Long's useful life. He took no further steps to enforce his claims, but patiently laboured for his country and his people through the troublous years of the war, and at length, when brighter days returned, he built up again his practice and ultimately died in harness, his last words being an anxious inquiry as to the welfare of a patient at whose bedside he was when his mortal sickness seized him.

There have been memorials erected to the memory of Long, the discoverer of ether anæsthesia, one in Paris and one at Jefferson, Georgia, and in Boston men see a monument in white marble bearing the inscription: "To the Discoverer of Anæsthesia." It bears no name.

Shall we not in England accord the first place to Long, and in no unfriendly spirit claim for Morton and Wells less exalted

[3] Letter from Dr. Davis written 12 years after the patent was granted to Morton for his letheon, showing that he attempted to enforce patent rights:—"U.S. Marine Hospital, Chelsea, Massachusetts, April, 1859. Dr. Crawford W. Long, Athens, Georgia. Sir,—Hon. Judge Hyllier, Solicitor of Treasury Department, informed me about a year since, and recently repeated the same, that some years since you used sulphuric ether as an anæsthetic and had a record of the same. If it is not asking too much of you I would be greatly obliged if at your earliest convenience you would forward me a statement of the facts. I take the liberty to ask this of you because Mr. W. T. G. Morton, to whom in conjunction with Dr. C. T. Jackson a patent was granted in November, 1846, for using ether, has brought a suit against me as a Government Officer for an infringement of his patent. Judge Hyllier was confident that you could furnish me with proof sufficient to satisfy a jury that you used it in this way before he or Jackson claimed to have made the discovery. I should have asked for these proofs through my attorney and had them properly witnessed, &c., but the Secretary of the Treasury having decided that I used the article on my own responsibility, and therefore the Government were not bound to defend me, I wish to save as much expense as possible.—Very respectfully, (signed) CHARLES A. DAVIS, M.D., Physician and Superintendent."

[4] Dr. Jackson published a full account of this interview and the steps he took to verify Dr. Long's statements. See Boston Medical and Surgical Journal, April 11th, 1861.

niches in the Temple of Fame; for we may not forget that to them, and indeed to Dr. Jackson, the world owes very much, since, if not the first to employ ether as an anæsthetic, they made themselves the heralds of an epoch-making discovery, and they were in ignorance when they did so that Crawford Williamson Long had anticipated them?

(To be continued.)

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

Notification of Cerebro-Spinal Meningitis and Poliomyelitis.

THE Public Health Committee reported to the London County Council on Feb. 27th with regard to the compulsory notification of epidemic cerebro-spinal meningitis and acute poliomyelitis or acute polio-encephalitis. As to cerebro-spinal meningitis, the committee stated that this disease had been compulsorily notifiable in London since March 12th, 1907. During the time that had elapsed since that date, 656 cases had been notified, and detailed information, which might become valuable at any time, had been accumulated. Considerable attention had been given to this disease during recent years in the principal cities of Europe and America, and the committee regarded it as of importance that in London the continuity of statistical information should be preserved. Acute poliomyelitis was made compulsorily notifiable on Sept. 1st, 1911, and since then 50 cases of the disease had been notified. The disease occurred principally among children, 11 or 12 per cent. of the cases proving fatal, and infantile paralysis frequently resulting among those who survived.

The committee recommended that both these diseases should be added to the list of diseases permanently notifiable under Section 55 of the Public Health (London) Act, 1891, and the Council approved of this, and decided that they be so notifiable from and including March 13th, 1912.

The Deputy Medical Officer of Health.

With reference to the Council's authorisation of the appointment of a deputy medical officer of health and deputy school medical officer for the County of London at a salary of £1000 a year, the Establishment Committee reported that 30 applications for the position had been received and 10 selected candidates had been interviewed. In the opinion of the committee Mr. W. Butler, M.S., M.B. Glasg., D.P.H. Lond., medical officer of health and school medical officer for Willesden, was the candidate best fitted for the position, and it accordingly recommended his appointment. In compliance with the standing order requiring three names to be submitted to the Council the committee also mentioned the names of Mr. Alfred Greenwood, M.D., B.S., B.Sc. Vict., D.P.H. Irel., L.R.C.P. & S. Edin., L.F.P.S. Glasg., barrister-at-law, and Mr. William Henry Whitehouse, M.D., B.S. Durh., D.P.H. Edin., barrister-at-law. On March 5th the appointment of Dr. Butler was approved by the Council.

The Medical Treatment of School Children.

It was reported at the meeting of the Education Committee of the London County Council on Feb. 28th that the Board of Education had expressed its views with regard to the experimental schemes for the treatment of children suffering from suppurating ears through the agency of various nursing institutions, which the Council has carried on in different parts of London during the last three years. The Board stated that it was very desirable that the question of the treatment of minor ailments in the county as a whole should be fully investigated by the Council, and it was reluctant to approve an isolated undertaking of this nature providing for the treatment of one type of ailment in one part of the county. If satisfactory results were to be obtained it was essential that the question should be considered as a whole in close connexion with the Council's scheme of medical inspection, the Council not committing itself in the meantime to isolated experiments which might prove subsequently a source of embarrassment in preparing a general scheme of treatment. For these reasons the Board was not willing, on the information before it, to sanction a proposed extension of the experiments in Camberwell.

In reply to this communication the Children's Care Committee stated that unless some such arrangements as those proposed were made many children in the district would be unable to obtain treatment. The committee recommended that the Board be urged to approve the experiment as a temporary measure on the understanding that the scheme would be under the supervision of the Council's school medical officer. The committee also suggested that the Board of Education be informed that the Council would be prepared to consider a general scheme for nursing treatment when a grant as promised on behalf of the Government should have been made in respect of the medical service.

The committee decided to advise the Council to send a communication on these lines to the Board of Education.

The Council has received the following letter from the Board of Education, dated Feb. 21st:—

SIR,—With reference to Sir Laurence Gomme's letter of the 12th December last, I am directed by the Board of Education to state that, under the code of regulations for public elementary schools, 1909, as modified by the minute of the Board of Education, dated June 25th, 1910, they are satisfied that provision has been made by the local education authority for the medical inspection of children attending the public elementary schools within the area of the authority for the year ending on the 31st July, 1912.

I am, &c.,
(Signed) GEORGE NEWMAN.

"The Maudsley Hospital."

The Asylums Committee has received an inquiry from the Lunacy Commission as to the name by which it was proposed that the mental hospital to be erected at Denmark Hill should be known, and has addressed a communication to Dr. Maudsley on the subject, who, in reply, has intimated to the great pleasure of the committee that he did not object to the use of his name in connexion with the title for the new institution. The committee has therefore determined that the hospital shall be known as "The Maudsley Hospital." The members felt that no more appropriate name could be chosen, and have expressed themselves as glad of the opportunity of thus permanently associating Dr. Maudsley's name with the good work to be carried on in the hospital which owed its establishment to his timely suggestion, and towards the cost of which he had made so generous a contribution.

Medical Superintendent of Long Grove Asylum.

In reporting the resignation by Dr. C. Hubert Bond of his appointment as medical superintendent of Long Grove Asylum, on his appointment by the Lord Chancellor to be a Commissioner in Lunacy, the Asylums Committee stated that Dr. Bond had been in the service of the Council for 19 years, and had been medical superintendent of the Epileptic Colony as well as of Long Grove Asylum. At both these institutions his care and forethought for the patients in his charge, his desire for the welfare of the staff, and his thorough administration had earned the highest approbation of the committee, which, while it congratulated Dr. Bond on his new appointment, regretted that the County of London would lose his valuable services.

FAR EASTERN ASSOCIATION OF TROPICAL MEDICINE.

THIS association held its Second Biennial Congress at Hong-Kong from Jan. 20th to 27th, under the presidency of Dr. J. MITFORD ATKINSON, of Hong-Kong. One hundred and fourteen members of the medical profession practising in the Far East were present, including the official delegates from the Governments of India, Ceylon, Netherlands-India, French Indo-China, Federated Malay States, Straits Settlements, Philippine Islands, Kiautschou (Imperial German Government), Macao, China, Japan, and the Commonwealth of Australia.

His Excellency Sir FREDERICK LUGARD, G.C.M.G., Governor of the Colony, in an address of welcome, referred to the foundation of the association on the initiative of the Bureau of Science of the Philippines in 1910. He spoke in terms of eulogy of the Tung Wah Hospital in Hong-Kong, which is entirely managed and controlled by an annually elected board of Chinese gentlemen, under the supervision of the Registrar-General, with a Government inspecting medical officer, and also of the University of Hong-Kong, which will shortly be opened with its first Faculty, that of medicine. He hoped that when next the association met in Hong-Kong it would assemble in the great hall of the University.

The PRESIDENT then delivered his address on the

"Progress of Tropical Medicine during the Past 25 Years." He traced the history of the discovery of the malarial parasite, and its transmission to man by the mosquito, and detailed the work done by the Government in Hong-Kong in malaria prevention, with the result that the number of admissions for malaria to the two largest civilian hospitals had fallen from an average of 971 in the quadrennium 1897–1900 to 693 for 1901–05, and to 594 for 1906–10. He showed how the seriousness of plague had diminished since Governor Sir Henry Blake in 1903 succeeded, by a practical demonstration of what could be accomplished by the people themselves by a thorough cleansing of their houses and clothing, in obtaining the coöperation of the Chinese population.

Scientific Meetings.

The whole of Jan. 22nd was devoted to Beri-beri, papers being read by Major Weston P. Chamberlain, M.D., and Captain Edward Vedder, M.D. (Manila); C. Noel Davis, M.B. (Shanghai); Victor G. Heiser, M.D. (Manila); L. Bréaudat, M.D. (Saigon); Dr. Legendre (Hanoi); H. Fraser, M.D. (Kuala Lumpur); Professor Teruuchi, M.D. (Tokyo); Colonel Makita (Tokyo); and Dr. Tsuzuki (Japan). An interesting discussion took place, and eventually the following resolution was passed:—

That the accuracy of the opinion of this association, recorded in 1910, has received further and more complete confirmation by investigators in Japan, China, French Indo-China, the Philippine Islands, Siam, Netherlands-India, the Straits Settlements, and the Federated Malay States—namely, that "beri-beri is associated with the continuous consumption of white (polished) rice as the staple article of diet."

It was therefore again desired to bring this opinion to the notice of the various Governments concerned and to recommend international action.

Jan. 23rd was devoted to Dysentery, Cholera, Intestinal Parasites, and Plague, papers being read and discussed on the Multiplication of Amœbæ of the Human Intestine, by A. Gauducheau, M.D., Médecin-Major (Hanoi); the Action of Ipecacuanha on Amœbæ, by Captain Vedder, M.D. (Manila); the Surgical Treatment of Dysentery, by O. Müller, M.D. (Hong-Kong); the Bacteriological Diagnosis of Cholera, by Professor Teruuchi, M.D., and O. Hida, M.D. (Tokyo); the Source of the Human Liver Distome (Clonorchis endemicus, Bälz), by H. Kobayashi, M.D. (Tokyo); Intestinal Parasites of Man in Hong-Kong, by J. Bell, M.R.C.S. (Hong-Kong); Immunisation against Pneumonic Plague, by Richard P. Strong, M.D. (Manila); Preventive Inoculation in Experimental Plague-Pneumonia, by Professor G. Shibiyama (Tokyo); the Connexion between Man and Rat in the Plague Epidemic in Malang, Java, during 1911, by W. L. de Vogel, M.D. (Batavia). This last paper was accompanied by an interesting series of lantern photographs, showing how the rats were found in the bamboo supports of the native houses.

On Jan. 24th papers were read on the Prophylaxis of Syphilis in Natives by "606," by M. L. R. Montel, M.D. (Saigon); the Care of the Eyesight in the Tropics, by G. M. Harston, M.D. (Hong-Kong); Vesical Calculi in South China, with a Report of more than 1000 Cases, by J. M. Swan, M.D. (Canton); Carbon-Dioxide Snow in Private Practice in the Tropics, by G. P. Jordan, M.B. (Hong-Kong); Results of the Past Two Years' Work in the Study of Tropical Sunlight, by Paul C. Freer, M.D. (Manila). There was no afternoon session on this day.

On Jan. 25th papers were read on Opium Poisoning, by A. Gauducheau, M.D., Médecin-Major (Hanoi); Care of Children in the Tropics, by G. M. Harston, M.D. (Hong-Kong); The Need for Physiological Standards in Clinical Research, by G. D. Whyte, M.B. (Swatow); The Prophylaxis of Umbilical Tetanus at Saigon, by M. L. R. Montel, M.D. (Saigon); Latest Researches into Spotted Fever, by Staff-Surgeon Dr. Fürth (Tsingtau); Relapsing Fever and its Treatment by Salvarsan, by W. V. M. Koch, M.D. (Hong-Kong); Miliary Fever, by Dr. Sairailhé (Bienhoa, Cochin China); and Blood Pressure, by J. C. Dalmahoy Allen, M.D. (Hong-Kong).

Jan. 26th was devoted to the subject of malaria and public health, and papers were read on Malaria as a Factor in the Etiology of Biliary Calculi, by G. A. Finlayson, M.B. (Singapore); Remarkable Parasites in a case of Tertian Malaria, by Captain H. M. Neeb, M.D. (Batavia); A Revision of the Anopheline Mosquitoes of British Malaya, by Major S. P. James, M.B., I.M.S. (Simla); Ceratopogon Parasitic on Anopheles, by A. T. Stanton, M.D. (Kuala Lumpur); Blackwater Fever in Burma, by L. J. Fink, M.B. (Burma); Anti-malarial Campaign in Formosa, by Dr. Hatori (Formosa); Mortality, Birth-rate, and Sanitation in Saigon, by M. L. R. Montel, M.D. (Saigon); Indian Native Immigration, by Sir Allan Perry, M.D. (Ceylon); and the Necessity for Uniform Quarantine Regulations for all the Coast Ports of China, by Fleet-Surgeon Dr. Uthermann (Tsingtau).

The association adopted a report to secure uniformity in quarantine at Eastern ports, the main points in which were: 1. The establishment of a definition for the term "status sporadicus" and a common standard for the term "epidemic." The definitions suggested were: *Status sporadicus* in respect of any communicable disease means the existence in a place, within the next preceding 14 days, of a case or cases of that disease, not definitely traceable to an imported case. *Status epidemicus:* Plague, cholera, small-pox, typhus exanthematicus, trypanosomiasis, or other communicable diseases shall be considered to be epidemic in any port, place, or defined locality, when after the first telegraphic report of the appearance or recrudescence of the disease, any weekly report thereafter shall show the occurrence of an average daily number of three cases, exclusive of cases imported into, or originating in, a quarantine station. 2. Circulation among the signatories of weekly returns of plague (human or rodent), cholera, small-pox, yellow fever, typhus, trypanosomiasis, and telegraphic information of first occurrence in a clean territory. 3. To issue a bill of health to all outgoing vessels detailing the facts as to quarantinable disease in the territory of departure. 4. To report by telegram to destination the departure of an infected or suspected ship, and endorse the ship's bill of health with full particulars as to disinfection practised. 5. Ships from a plague-infected place or carrying persons or suspected cargo therefrom, but showing no evidence of plague in man or rodent, shall not be disinfected at ports of call, if it can be shown that the vessel has been properly treated for vermin, the persons on board and their effects properly disinfected, and objectionable classes of cargo rejected or properly disinfected.

Jan. 27th was devoted to the business meeting. An invitation for the next biennial congress to be held at Saigon in 1913–14 was accepted. Votes of thanks were given to various officers and others—especially to Dr. Francis Clark, the honorary secretary, for his invaluable work in connexion with the Congress.

Exhibits.

Dr. J. M. Swan, Canton, lent a collection of 1000 vesical calculi; Mr. W. J. Tutcher, Hong-Kong, herbarium specimens of medicinal plants found growing in China; and the Tung Wah Hospital, Hong-Kong, Chinese drugs in common use. Messrs. Burroughs, Wellcome, and Co., London, exhibited "Wellcome" brand quinine, quinine hydrochloride tabloids, "epinine" for syphilis and trypanosomiasis, tabloid medicine cases, and other pharmaceutical preparations; Messrs. Down Bros., London, surgical instruments and aseptic furniture; Messrs. Allen and Hanburys, London, surgical instruments and "Allenbury" specialities; and E. Leitz, Wetzlar, microscopes and bacteriological instruments and apparatus.

THE LONDON SCHOOL OF CLINICAL MEDICINE.

THE annual dinner of this institution was held under the presidency of H.S.H. Prince LOUIS of BATTENBERG in the rooms of the Royal Institute of Painters in Water Colours, Piccadilly, W., on March 1st, when covers, distributed among 24 tables, were laid for more than 170 persons. The chairman, with Sir Thomas Barlow, Admiral Sir John Durnford, Director-General Sir James Porter, R.N., Mr. Rickman J. Godlee, and Sir Malcolm Morris, occupied one table, while the remaining 23 tables were apportioned among other members of the school and their guests, among whom may be mentioned Sir William Bennett, Surgeon-General Sir Arthur Branfoot, I.M.S. (retired), Sir James Crichton-Browne, Sir Henry Burdett, Sir James Mackenzie Davidson, Sir Dyce Duckworth, Sir John Rose Bradford, Director-General Sir W. Launcelot Gubbins, Sir Frederic Hewitt, Professor R. T. Hewlett, Admiral Swinton Holland, Admiral

H. W. Savory, Captain A. W. Clarke, Professor W. J. R. Simpson, C.M.G., Dr. S. Squire Sprigge, Dr. Frederick Taylor, Mr. C. Louis Taylor, Dr. C. C. Choyce (Dean of the School), and Mr. P. J. Michelli, C.M.G. (secretary of the Seamen's Hospital).

In proposing the toast of the evening, the CHAIRMAN pointed out that the School of Clinical Medicine was founded in 1906 for the purpose of affording for post-graduate students an opportunity of bringing themselves into touch with the most recent developments in medicine and surgery. It was felt that at the Dreadnought Hospital there existed a large amount of clinical material which was lost to education, and the sanction of the committee of the Seamen's Hospital Society having been obtained the school received the sympathy and help of the leading physicians and surgeons of the medical profession. During the first year's work 68 students attended, and since that time the activities of the school had steadily been extended. Since 1906, 560 students had been enrolled, composed of all classes of medical men coming from Great Britain and Ireland, Canada, United States of America, Peru, Nicaragua, Chili, Brazil, Argentine, Spain, Greece, Holland, Germany, France, India, China, Straits Settlements, Australia, New Zealand, and South Africa. The school had been well attended by officers of the medical services either before or after their entry into those services. From the very first the naval surgeons seconded for study had availed themselves of the advantages of the new school, and within the last 18 months, owing to the action of the Durnford Commission, acting in conjunction with the Director-General of the Medical Department of the Navy, Sir James Porter, systematic courses of instruction had been attended by from 20 to 30 officers annually. It was hoped that in the future a still closer connexion would be established between the Clinical School and the Royal Naval College at Greenwich. The Dreadnought Hospital and Clinical School afforded one of the most complete courses of operative surgery in the kingdom, and negotiations were also in progress whereby the post-graduate student would be afforded instruction in practical medicine. After complimenting the board of management of the Seamen's Hospital on its excellent work, His Serene Highness pointed out that hospitals were charitable institutions supported by a generous public. Everyone who realised what the nation owed to men of the mercantile marine should contribute to the maintenance of such excellent and necessary institutions as those of the Seamen's Hospital Society, and although the present occasion was not one in which he had been desired to make an appeal for money he would hint to those who were generously disposed that additions to the financial resources of the society would be more than welcomed.

Sir MALCOLM MORRIS, with whose name the toast had been coupled, in his reply said that the appointment of His Serene Highness (who had made the dinner a success by his presence in the chair that evening) to the office of a Sea Lord had given the most profound gratification to every Englishman. Comparing the progress which had been made in naval matters and in medicine, he pointed out an almost exact coincidence. The change from the old wooden ship to the modern Dreadnought, the torpedo boat, and the submarine was as great a revolution as that which had taken place in medicine owing to the action of one man, a man whom they had laid to rest within the last few days, Lord Lister. We trusted in the navy for our protection, and what the navy did for our shores and our homes Lord Lister had done for our bodies. Sir Malcolm Morris also referred to the introduction and use of the Roentgen rays and the enormous advance in medicine due to this agent owing to the work of, among others, Sir Mackenzie Davidson, and drew an interesting comparison between the deep-sea sounding experiments of Lord Kelvin and modern methods of exploring the cavities of the human body. Referring to the need for post-graduate studies, he said that the greatest insurance that could be given to the nation was the insurance of a highly skilled and highly educated doctor, and they were greatly indebted to the head of the Navy Department for allowing the naval surgeons to use the clinical school for instruction.

Captain A. W. CLARKE proposed the toast of "The Medical Services" with considerable happiness, departing from the formal statement, with which he had been supplied by the authorities, to detail his own experiences, as one who had been all over the world, of the vast debt which scattered communities owe to the ministrations of medicine.

Director-General Sir JAMES PORTER, who replied, said that it was now recognised that only the best that the medical profession could furnish was good enough for the service which he represented, and referred to the connexion between the Royal Naval Medical Service, the Royal Army Medical Corps, the Indian Medical Service, and the Colonial Services, which was now being recognised so that those services were not going to live any longer in water-tight compartments.

Sir JOHN ROSE BRADFORD, who proposed "The Guests," referred with gratitude to the great interest which the Colonial Office and successive Colonial Secretaries had taken in the advancement of tropical medicine. With the toast he coupled in humorous phrases the names of Sir Thomas Barlow (the President of the Royal College of Physicians of London) and Mr. Rickman Godlee (the President of the Royal College of Surgeons of England), who both made suitable replies.

The dinner was the largest ever held by the school.

Public Health.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

County of East Sussex.—Mr. A. G. R. Foulerton attributes an important share in the reduction of infant mortality in this county to the influence of the large number of trained midwives introduced into the rural districts by the Sussex Nursing Association, and to the supervision of untrained midwives by the county authorities. In the class of mothers among whose infants the highest mortality occurs it is often of little use to distribute leaflets, however well prepared, while women health visitors are prone to be looked on with suspicion and considered unpractical. The midwife, on the other hand, nearly always has the mother's full confidence, and her advice usually determines the mother's treatment of her infant. In January, 1911, the midwives under supervision numbered 159, of whom 86 were trained. Out of 1931 maternity cases in which the midwives acted as such, and not as monthly nurses, it was necessary for them in 193 instances to send for medical aid on behalf of the mother or the infant. During 1910 the rate of reported still-births was 1 for every 74 confinements. The report reviews a variety of subjects arising out of the annual reports from individual districts in the county for 1910, and, as is frequently the case with county reports, makes a somewhat late appearance in consequence of the time required to get all the data completed. In this instance, however, the delay has enabled the county statistics to be revised by the Census data of 1911, which showed that the aggregate of the several local estimates of population was some 10,000 in excess of the actual figure.

County of Kent.—Dr. W. J. Howarth's report gives a further illustration of the great progress which has been made in many directions in organising the county sanitary service. It contains some important observations on the condition of the encampments of hop-pickers which should be seriously considered by those concerned. Where huts are employed it is common to find no provision for surface drainage and no rain-water spouting, with the result of much dampness and discomfort to the occupants. The tents used are often unsatisfactory, particularly for the women and children, being badly pitched and not watertight. The by-laws require cooking-houses to be thoroughly cleaned and kept clean, but unfortunately do not insist on cooking-houses being provided. The privy accommodation is also generally inadequate, and in Maidstone rural district Dr. Tew refers to the liability which still exists for the pollution of water-supplies, and expresses the fear that the lessons of the typhoid epidemic of 1897 are being forgotten or ignored. It would seem that the encampments of hop-pickers are in many places of a considerable size, and there is much to be said for the local authority detailing special men during the picking season to supervise the scavenging arrangements and ensure the protection of water-supplies. Frequent inspection of the foodstuffs brought in barrows to these encampments is also particularly necessary.

City of York.—Dr. Edmund M. Smith's annual report for this city is interesting reading as showing the care which is given to all branches of public health administration. It is reasonable to conclude that the notable decline in the

general death-rate and also in the mortality from tuberculosis and diseases of infancy which has characterised York during the past decade is to be attributed to a material extent to the increased efficiency of the municipal sanitary work. The efforts already made in various directions to combat tuberculosis are particularly striking, and the experience gained should be invaluable now that the administrative conditions are altered by general notification of pulmonary tuberculosis and by the prospect of sanatorium provision being available on a large scale. There are three school nurses for the city whose work is combined with that of health visiting. In the latter duties the rule that no notes should be taken by the health visitor at the homes is at first sight arbitrary, but has much to commend it. The results of inquiries made as to the practice of different towns in dealing with tuberculous meat show that while the recommendations of the Royal Commission of 1898 are usually taken as the standard they are frequently departed from. In York the entire carcass is not condemned when tuberculous lesions are present in both body cavities but are "in the early stages," or even when they are present in the muscular system or in the lymphatic glands embedded in the muscles. Cases in which the latter conditions obtain do not often come under notice in meat inspection, but when they do there is usually substantial ground for total condemnation. The employment of a veterinary meat inspector, who acts with the sanitary inspectors in systematic inspection of the numerous private slaughter-houses, has had satisfactory results, while butchers, as a result of their system of insurance, show an increasing disposition to consult the sanitary authorities in all cases of doubt. In advising on the destruction of rats Dr. Smith lays stress on the advantages of using bacterial virus and on the harmlessness of the virus to man. The latter statement needs the qualification that the virus should not be allowed to contaminate food or places where food is kept. A substantial beginning appears to have been made in applying the provisions of the Housing Act and regulations to insanitary property in York.

Metropolitan Borough of Wandsworth.—A bulky volume has lately been issued by the borough council which comprises a mass of information relating its general administration up to March 31st, 1911, and includes the reports of the medical officer of health and the public analyst for 1910. These show that the proportion of samples of foods taken under the Sale of Food and Drugs Acts which proved to be adulterated or otherwise unsatisfactory was as high as 9 per cent., a figure attributed mainly to greater discrimination in the selection of the samples and to the improved methods employed in obtaining them. Among the adulterations reported the substitution for arrowroot of a flour containing 90 per cent. of tapioca may be mentioned. As Dr. P. Caldwell Smith points out, a comparison of the price paid for the arrowroot, 1*s.* 6*d.* a pound, with that usually paid for tapioca, 3*d.* a pound, shows that a large profit may be obtained by this practice. The amount of boron preservative in some samples of prepared meats was exceptionally high, in one case (sausages) reaching 55 grains per pound. Proceedings were taken against certain of the vendors and convictions obtained. This was also the case with a sample of cocoa containing 33 per cent. of extraneous shell, and with several samples where margarine was substituted for butter. The penalties usually imposed in these cases seem, however, to be much too small. A fine of £1, or even £5, is not enough to act as a deterrent to the practice of gross and profitable frauds such as are recorded in these reports. We would like to see more drastic action, for example, in the case of skim milk found to contain 44 per cent. of added water, or of the vendor who carries unadulterated milk in his large churn for the benefit of inspectors and casual purchasers, while habitually distributing adulterated milk in small cans to his regular customers.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 8793 births and 5194 deaths were registered during the week ending March 2nd. The annual rate of mortality in these towns, which had decreased from 21·6 to 16·8 per 1000 in the three preceding weeks, further declined to 15 4 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these large towns averaged 17·0 per 1000, while in London during the same period the average death-rate did not exceed 16·2 per 1000. The annual death-rates last week in the several towns ranged from 3 5 in Acton, 6·4 in Wallasey and Darlington, 7·5 in Ilford, and 8 0 in Lincoln, to 23·7 in Ipswich, 23·8 in Huddersfield, 24 6 in Merthyr Tydfil, 24 9 in Gloucester, and 26·8 in Great Yarmouth.

The 5194 deaths from all causes last week were 451 fewer than the number in the previous week, and included 394 which were referred to the principal epidemic diseases, against numbers declining from 435 to 353 in the three preceding weeks. These 394 deaths from the principal epidemic diseases included 142 which resulted from whooping-cough, 109 from measles, 53 from diphtheria, 49 from infantile diarrhœal diseases, 21 from scarlet fever, and 20 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1 2 per 1000, against 1·1 and 1·0 in the two preceding weeks. The deaths attributed to whooping-cough, which had decreased from 186 to 147 in the three preceding weeks, again declined to 142 last week, and caused the highest annual death-rates of 2 2 in Tottenham, 2·3 in West Bromwich, 2·8 in Walsall, and 3 8 in Merthyr Tydfil. The deaths referred to measles, which had been 98, 69, and 88 in the three preceding weeks, rose to 109 last week; the highest annual death-rates from this disease were 1·7 in Rhondda, 2 2 in Manchester, 2·5 in York, 2·7 in Salford, and 2 8 in Warrington. The fatal cases of diphtheria, which had declined from 71 to 44 in the four preceding weeks, rose to 53 last week, and included 23 in London and its 14 suburban districts, and 2 each in Birmingham, Grimsby, Manchester, Huddersfield, Rotherham, and Newcastle-on-Tyne. The deaths of infants under two years of age attributed to diarrhœal diseases, which had been 49, 58, and 39 in the three preceding weeks, rose to 49 last week; 23 deaths occurred in London and its suburban districts, and 3 each in Liverpool, Manchester, Salford, and Cardiff. The deaths referred to scarlet fever, which had been 22, 28, and 17 in the three preceding weeks, rose to 21 last week, and included 3 in Birmingham, and 2 each in London, Manchester, Preston, Huddersfield, and Leeds. The 20 fatal cases of enteric fever were 2 in excess of the average in the eight preceding weeks of the current quarter; 4 deaths were registered in Manchester, and 2 each in London, Salford, and Cardiff.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had decreased from 1512 to 1427 during the three preceding weeks, had further declined to 1392 on Saturday last; 160 new cases of this disease were admitted to these institutions during the week, against 178, 154, and 181 in the three previous weeks. These hospitals also contained on Saturday last 1136 cases of diphtheria, 462 of whooping-cough, 222 of measles, and 64 of enteric fever, but not one of small-pox. The 1228 deaths from all causes recorded in London were 106 fewer than the number in the previous week, and were equal to an annual death-rate of 14·2 per 1000. The deaths referred to diseases of the respiratory system, which had decreased from 545 to 352 in the three preceding weeks, further declined to 295 last week, and were 23 below the number registered in the corresponding week of last year.

Of the 5194 deaths in the 94 large towns, 172 resulted from different forms of violence, and 374 were the subject of coroners' inquests. The causes of 34, or 0·7 per cent., of the deaths registered last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Nottingham, Portsmouth, and in 66 other smaller towns. The 34 uncertified causes of death last week included 6 in Birmingham, 4 in London, and 2 each in Stoke-on-Trent, Dudley, St. Helens, Burnley, Blackburn, and Sunderland.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns, having an estimated population of 2,182,400 persons in the middle of this year, 1175 births and 784 deaths were registered during the week

ending March 2nd. The annual rate of mortality in these towns, which had decreased from 22·8 to 18·5 per 1000 in the three preceding weeks, rose to 18·7 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual rate of mortality in these towns averaged 19 1 per 1000, and was 2·1 per 1000 in excess of the mean rate recorded during the same period in the large English towns. The annual death-rates in the several Scotch towns last week ranged from 10·3 in Kirkcaldy, 12·9 in Clydebank, and 13·3 in Aberdeen, to 22·5 in Hamilton and in Kilmarnock, and 24·0 in Greenock.

The 784 deaths from all causes were 9 in excess of the number in the preceding week, and included 93 which were referred to the principal epidemic diseases, against numbers steadily rising from 89 to 120 in the five preceding weeks. Of these 93 deaths, 56 resulted from measles, 16 from whooping-cough, 9 from diphtheria, 6 from scarlet fever, 5 from infantile diarrhœal diseases, and 1 from enteric fever, but not one from small-pox. These 93 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·2 per 1000, or 1·0 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had averaged 62 in the three preceding weeks, declined to 56 last week, and included 27 in Glasgow, 7 in Greenock, 5 in Edinburgh, and 5 in Kilmarnock. The deaths referred to whooping-cough, which had been 14 and 18 in the two preceding weeks, slightly declined to 16, and of this number 4 were registered in Glasgow, 3 in Edinburgh, and 2 in Dundee. The fatal cases of diphtheria, which had been 6 and 22 in the two previous weeks, fell to 9 last week, and included 4 in Glasgow and 2 in Edinburgh. The 6 deaths attributed to scarlet fever were 3 in excess of the number in the previous week, and included 2 in Glasgow and 2 in Aberdeen. The deaths of infants referred to diarrhœal diseases, which had been 14 and 11 in the two preceding weeks, further declined to 5 last week. The fatal case of enteric fever was recorded in Kirkcaldy.

The deaths referred to diseases of the respiratory system in the 18 towns, which had decreased from 220 to 192 in the three preceding weeks, further declined to 138 in the week under notice, and 24 deaths were attributed to different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 673 births and 490 deaths were registered during the week ending March 2nd. The annual rate of mortality in these towns, which had decreased from 31·0 to 24·6 per 1000 in the three preceding weeks, further declined to 22 1 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these Irish towns averaged 23·5 per 1000; in the 94 large English towns the mean annual death-rate during the same period did not exceed 17 0 per 1000, while in the 18 Scotch towns it was equal to 19·1 per 1000. The annual death-rates in the several Irish towns last week were equal to 24·9 in Dublin (against 14·2 in London), 21·6 in Belfast, 21 1 in Cork, 12·7 in Londonderry, 16·3 in Limerick, and 19·0 in Waterford; while in the 16 smallest of these Irish towns the death-rate last week was equal to 21·0 per 1000.

The 490 deaths from all causes in the 22 Irish towns were 55 fewer than the number in the previous week, and included 36 which were referred to the principal epidemic diseases, against numbers declining from 49 to 27 in the three preceding weeks; of these 36 deaths, 16 resulted from whooping-cough, 9 from diarrhœal diseases, 5 from measles, 3 from scarlet fever, and 3 from diphtheria, but not one from enteric fever or from small-pox. These 36 deaths from the principal epidemic diseases were equal to an annual death-rate of 1 6 per 1000; the death-rate last week from these diseases did not exceed 1·2 per 1000 in the 94 large English towns, while in the 18 Scotch towns it was equal to 2 2. The deaths attributed to whooping cough, which had declined from 25 to 14 in the three preceding weeks, rose to 16 last week, and included 11 in Belfast and 3 in Dublin. The deaths of infants referred to diarrhœal diseases, which had been 8 and 5 in the two previous weeks, rose to 9 last week; 4 deaths were recorded in Dublin, 2 in Belfast, and 2 in Clonmel. The 5 fatal cases of measles were equal to the average in the three preceding weeks, and were all registered in Dublin. The 3 deaths referred to scarlet fever, and the 3 fatal cases of diphtheria were also registered in Dublin.

The deaths referred to diseases of the respiratory system, which had decreased from 239 to 189 in the three preceding weeks, further declined to 135 last week. Of the 490 deaths from all causes in the 22 Irish towns, 142, or 29 per cent., occurred in public institutions, and 7 resulted from different forms of violence. The causes of 17, or 3·5 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 large English towns the proportion of uncertified causes of deaths in the week under notice did not exceed 0·7 per cent.

VITAL STATISTICS OF LONDON DURING JANUARY, 1912.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 5·3 per 1000 of the population, estimated at 4,519,754 persons in the middle of the year. In the three preceding months the rates were 8·5, 7·8, and 6·3 per 1000 respectively. The lowest rates last month were recorded in Paddington, Hammersmith, City of Westminster, Stoke Newington, and Shoreditch; and the highest rates in Hampstead, St. Pancras, Holborn. Deptford, and Greenwich. Three cases of small-pox, all belonging to Woolwich, were notified last month, none having been notified in London during the six preceding months; 2 cases remained under treatment in a Metropolitan Asylums Hospital at the end of the month. The prevalence of scarlet fever continued to show a decline; this disease was proportionally most prevalent last month in Fulham, Chelsea, St. Marylebone, Deptford, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 1473 scarlet fever patients at the end of the month, against 2152, 2103, and 1878 at the end of the three preceding months; the weekly admissions averaged 165, against 317, 254, and 198 in the three preceding months. Diphtheria was slightly less prevalent than it had been in the preceding month; the greatest proportional prevalence of this disease was recorded in Hampstead, St. Pancras, Holborn, Poplar, Greenwich, and Lewisham. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1143, 1327, and 1294 at the end of the three preceding months, had further declined to 1191 at the end of last month; the weekly admissions averaged 134, against 168 and 180 in the two preceding months. Enteric fever also was less prevalent than in the previous month; this disease was proportionally most prevalent last month in Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Lambeth. There were 49 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 160, 85, and 76 at the end of the three preceding months; the weekly admissions averaged 8, against 9 in each of the two preceding months. Erysipelas was proportionally most prevalent in Holborn, Shoreditch, Bethnal Green, Poplar, Battersea, and Deptford. The 39 cases of puerperal fever notified during the month included 5 in Kensington, 5 in Stepney, 4 in Fulham, and 3 each in the City of Westminster, Poplar, Southwark, and Camberwell. Ten cases of cerebro-spinal meningitis, including 3 in Paddington; and 4 of poliomyelitis, including 2 in Camberwell, were notified during the month.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the five weeks ending Feb. 3rd the deaths of 6736 London residents were registered, equal to an annual rate of 16·3 per 1000; in the three preceding months the rates had been 15·1, 14·1, and 16·1 per 1000. The death-rates last month ranged from 11·7 in Hampstead, 13·1 in Wandsworth, 13 6 in Stoke Newington, 13·9 in Lewisham, 14·0 in Camberwell, and 14·2 in Hackney, to 19·2

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JANUARY, 1912.

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.

in Chelsea, 19·6 in Bermondsey, 20·2 in Poplar, 20·7 in Finsbury, 21·2 in Shoreditch, and 22·1 in the City of London. The 6736 deaths from all causes included 310 which were referred to the principal epidemic diseases; of these, 1 resulted from small-pox, 63 from measles, 9 from scarlet fever, 55 from diphtheria, 78 from whooping-cough, 16 from enteric fever, and 88 from diarrhœa and enteritis among children under 2 years of age. The lowest death-rates from these diseases in the aggregate were recorded in Hammersmith, Stoke Newington, Holborn, Bethnal Green, Camberwell, and Woolwich; and the highest rates in Shoreditch, Poplar, Bermondsey, Deptford, and Greenwich. The 63 deaths from measles were 151 below the corrected average for the corresponding period of the five preceding years; the greatest proportional mortality from this disease was recorded in Paddington, Islington, Bermondsey, Deptford, and Greenwich. The 9 fatal cases of scarlet fever showed a decline of 34 from the corrected average number. The 55 deaths from diphtheria were 31 below the average; this disease was proportionally most fatal in Hampstead, St. Pancras, Shoreditch, Poplar, and Bermondsey. The 78 fatal cases of whooping-cough were 74 fewer than the corrected average number; the greatest proportional mortality from this disease was recorded in Paddington, Islington, Shoreditch, Poplar, and Greenwich. The 16 deaths from enteric fever were 6 below the average, and included 4 in Lambeth, 2 in Stepney, and 2 in Lewisham. The mortality from diarrhœa and enteritis among children under two years of age was proportionally greatest in St. Pancras, Finsbury, Shoreditch, and Stepney. In conclusion, it may be stated that the aggregate mortality in London last month from the principal epidemic diseases (excluding diarrhœa) was 40 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: R. A. Ross to the *Hindustan;* H. W. Gordon-Green to the *Collingwood;* and R. J. MacKeown to the *Vanguard.* Staff-Surgeon: W. K. Hopkins to the *Commonwealth.* Surgeons: J. C. F. D. Vaughan to the *Vanguard;* H. B. German to the *Collingwood;* and M. H. Langford to the *Halcyon*, additional, for the *Spanker.*

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel William A. Morris is placed on retired pay (dated March 1st, 1912).

Major William Hallaran to be Lieutenant-Colonel vice W. A. Morris (dated March 1st, 1912).

The undermentioned Captains to be Majors (dated Feb. 29th, 1912): Francis P. Lauder and John Tobin.

Surgeon-General J. G. MacNeece has been selected for appointment as Principal Medical Officer of the Southern Command, in succession to Surgeon-General H. R. Whitehead, C.B., with effect from April 1st.

Colonel R. I. D. Hackett, principal medical officer of the Karachi Brigade, has been granted six months' combined leave of absence home from India. Colonel W. W. Pike, D.S.O., lately senior medical officer at Cairo, has taken up duty as Principal Medical Officer of the Bombay Brigade, in succession to Colonel R. H. Forman, honorary surgeon to H.E. the Viceroy, who has been placed on retired pay. Colonel W. G. Macpherson, C.M.G., principal medical officer of the Fourth (Quetta) Division, has been appointed an Honorary Surgeon to the King.

Lieutenant-Colonel M. J. Sexton, lately holding medical charge of the Military Hospital, Arbor Hill, Dublin, has taken up duty at Wynberg. Lieutenant-Colonel J. Donaldson, in charge of the isolation hospital at Aldershot, has embarked for a tour of duty in India. Lieutenant-Colonel E. A. Burnside, from Golden Hill, has been appointed to command the Station Hospital at Bellary, Madras Presidency. Lieutenant-Colonel J. M. F. Shine, on return from Fyzabad, has been appointed Senior Medical Officer at Jersey, vice Lieutenant-Colonel F. P. Nichols. Lieutenant-Colonel L. T. M. Nash, on completion of a tour of service in India, at Karachi, has been appointed to hold charge of the Military Hospital at Hounslow. Lieutenant-Colonel T. G. Lavie, at present serving at Queenstown, has been placed under orders for a tour of service in Malta.

Major R. W. Clements, specialist sanitary officer of the Ninth (Secunderabad) Division, has been appointed to the substantive charge of the enteric fever convalescent depôt at Wellington, on relief by Captain W. R. Galwey. Major L. Humphry, specialist in advanced operative surgery to the Sixth (Poona) Division, has been granted six months' general leave of absence home from India, with effect from March 30th. Major E. P. Connolly, on arrival in India for a tour of service from Cardiff, has been posted to the Second (Rawal Pindi) Division. Major H. Herrick has been transferred from Hyderabad to the Station Hospital at Naini Tal. Major G. M. Goldsmith, from Maymyo, has been appointed to command the Station Hospital at Thayetmyo, Burma. Major H. H. Norman, from Kasauli, has taken up duty at Shwebo. Major H. S. Roch has been transferred from Lincoln to the Military Hospital at York for duty. Major J. M. Cuthbert, from Leith, has been appointed to the Military Hospital at Edinburgh. Major A. Chopping has been transferred from Cherat to Peshawar. Major J. G. MacNaught, on completion of a tour of service in South Africa, has been appointed to the Aldershot Command. Major E. C. Freeman has been granted by the War Office one year's extension of his appointment as Staff Officer to the Administrative Medical Officer of the East Anglian Division.

Captain T. J. Potter, specialist in bacteriology, has left the London District for service in Egypt. Captain E. V. Aylen, specialist in dermatology, Fourth (Quetta) Division, has been granted eight months' general leave of absence home from India. Captain H. Rogers, stationed at Fort Westmoreland, has been placed under orders for a tour of service in Malta. Captain A. H. Bond, from Naini Tal, has joined the Station Hospital at Delhi for duty. Captain C. T. Connyngham has been appointed Specialist in Dermatology and Venereal Diseases to the Fourth (Quetta) Division. Captain J. A. Bennett has been appointed Specialist in X rays and Electrical Science to the Sixth (Poona) Division. Captain D. M. Corbett has been granted eight months' general leave of absence home from India. Captain R. F. O'T. Dickinson has been transferred from Jhansi to the Station Hospital at Bareilly. Captain F. A. McCammon, at present serving at Poona, has been placed under orders for duty at Colaba. Captain B. A. Craig and Captain H. M. J. Perry have arrived home on duty from Hong-Kong; the former has been posted to Aldershot and the latter to the Eastern Command.

Lieutenant H. S. Blackmore and Lieutenant M. Drummond have been posted to the London District. Lieutenant E. S. Calthorpe has been appointed to Queen Alexandra Military Hospital at Millbank for duty. Lieutenant A. W. Bevis, Lieutenant M. J. Williamson, and Lieutenant C. L. Franklin have embarked for a tour of service in South Africa. Lieutenant T. W. Stallybrass has joined for service in Egypt. Lieutenant P. S. Tomlinson has embarked for a tour of duty in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel H. Fooks, at present holding medical charge of the 15th Lancers (Cureton's Multanis) at Risalpur, has been selected for appointment as officiating Principal Medical Officer of the Aden Brigade during the absence on leave of Lieutenant-Colonel H. F. Cleveland. The services of Lieutenant-Colonel B. B. Grayfoot have been placed at the disposal of the Government of Bombay. Lieutenant-Colonel J. Crimmin, V.C., C.I.E., has been appointed Presidency Surgeon of the Third District in Bombay. Lieutenant-Colonel A. Colman, civil surgeon at Rawal Pindi, has been granted one month's leave of absence.

On relief by Major T. G. N. Stokes of the office of Sanitary Commissioner of the Central Provinces, Major W. H. Kenrick has been placed on special duty in connexion with the prevention of malarial fevers in the Central Provinces. Major T. S. Horley has been transferred as District Medical Officer at Madura. The services of Major L. E. Gilbert have been placed at the disposal of the Government of Madras. Major H. Bennett has been selected for appointment as Civil Surgeon at Karachi. Major R. G. Turner on return from leave has been posted as Civil Surgeon at Naini Tal. The services of Major C. M. Matthew have been placed at the disposal of the Government of India for employment at Madras as Officiating Medical Storekeeper. Major H. J. K. Bamfield has been appointed Specialist in Midwifery and

Diseases of Women and Children to the Second (Rawal Pindi) Division.

Captain N. S. Sodhi has been transferred from Gurgaon to Ludhiana District as Plague Medical Officer. Captain H. W. Illius, Bengal Presidency, has returned to India from leave. Captain H. Ross, chief plague officer in the United Provinces, has been placed on special duty at Lucknow in connexion with the Prince of Wales Medical College. Captain A. W Howlett has been appointed Superintendent of the Central Prisons at Agra, vice Captain A. W. Overbeck-Wright. Captain A. F. Babonau, plague medical officer at Gurgaon, has been transferred to the Ambala district Captain H. B. Scott has been placed in charge of the Civil Surgeoncy at Shwebo until relieved by Captain W. Egan, R.A.M.C.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Thomas Lindsay is confirmed in his rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st South-Western Mounted Brigade Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains (dated Nov. 16th, 1911):—Lieutenant Thomas H. Haydon and Lieutenant James C. Burton.

2nd Wessex Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains (dated Dec. 25th, 1911):—Lieutenant Edward R. Clarke and Lieutenant Charles R. Crowther.

Attached to Units other than Medical Units.—Lieutenant Andrew Robertson to be Captain (dated Dec. 9th, 1911). Captain William B. Armstrong to be Major (dated Jan. 11th, 1912). Captain Robert J. W. Oswald resigns his commission (dated Feb 28th, 1912).

THE ROYAL ARMY MEDICAL COLLEGE.

The Director-General of the Army Medical Service and officers of the Royal Army Medical College entertained a numerous and distinguished company at a conversazione on Feb 23rd, thereby affording an opportunity for their guests to become acquainted with some of the many-sided activities of this branch of our profession. In the spacious and admirably lighted laboratories and museum of the educational portion of the institution were displayed many interesting exhibits, microscopic, electrical, and chemical, as well as those more especially of military medical appliances. The micro-organisms of the chief tropical diseases were shown in an almost exhaustive series of beautifully stained specimens, and special demonstrations were given by Lieutenant-Colonel Sir W. Leishman, F.R.S., of kala-azar and tick fever; while Captain J. C. Kennedy exhibited Mediterranean fever and trypanosomiasis. The latest method of staining spirochætæ was shown by Major L. W. Harrison, and Major W. S. Harrison and Major H. E. M. Douglas, V.C., D.S.O., demonstrated ankylostomiasis. In the hygienic laboratories Lieutenant-Colonel C. H. Melville and Major H. B. Fawcus showed various recent methods of water sterilisation, including the use of filters, heat, and electricity. A specially interesting exhibit was that by Major E. M. Pilcher, D.S.O., of the present field medical and surgical equipment of our military forces. From the surgical standpoint of to-day it would seem impossible to devise anything more comprehensive or complete, while the ingenuity displayed in economising space could not be surpassed. The Director-General and Lady Gubbins received their guests in the mess quarters, where refreshments were provided, and the band of the Royal Army Medical Corps performed during the evening. The mess is connected with the college by a sort of rialto the constructional arrangements being exceedingly well designed for the bodily comfort as well as the intellectual advancement of the officers of the corps. The Secretary of State was present and several members of the Army Council, to whom the evidences of intellectual alertness and a keen scientific spirit in this branch of military administration must have given great satisfaction.

ESPERANTO AND THE RED CROSS.

A knowledge of Esperanto would facilitate the ambulance work of the Red Cross, for it must often have happened on the field of battle that much suffering has resulted through a lack of understanding between the wounded man and the Red Cross worker. Already in France the military authorities have taken up the subject of Esperanto, and we are informed that there are many Esperantists in the French army. In this country but little attention has been paid to the matter probably because Esperanto has become associated with so many "isms" and cranky ideas, but many people apparently find it a fascinating hobby, and some commercial firms are using it to extend their business relations abroad. With the object of calling attention to the use of Esperanto in Red Cross work M. Privat visited Lord Haldane at the War Office on Feb. 29th. Lord Haldane, in answer to a question as to whether Esperanto could be introduced into the British Army, explained that the conservative nature of the English people would make official recognition very difficult, though he recognised the utility of Esperanto, more especially as it appeared to be spreading in China and Japan.

THE GRAND PRIORY OF THE ORDER OF THE HOSPITAL OF ST. JOHN OF JERUSALEM IN ENGLAND.

The King has sanctioned the following promotions in and appointment to the Order of the Hospital of St. John of Jerusalem in England:—As Knights of Grace: Mr. John Astley Bloxam (from Honorary Associate), Surgeon-General Hayward Reader Whitehead, C.B., and Dr. William Edmund Cant (from Honorary Associate).

Correspondence.

"Audi alteram partem."

EXOPHTHALMIC GOITRE.

To the Editor of THE LANCET.

SIR,—The discussion now proceeding at the Royal Society of Medicine induces me to offer the following suggestions on the pathology of Graves's disease.

Most authorities agree that it is a condition due to excessive absorption of thyroid colloid. The method by which the colloid is absorbed is not yet known. In the case of the normal gland it is often stated that the colloid stored in the lumina of the vesicles directly enters the lymphatic circulation. Intercellular communications have been described uniting the lymphatics and the vesicles, and a colloid-like substance is to be found in the lymph spaces of any thyroid section. The mechanism by which the colloid becomes transferred to the lymphatic spaces is not explained, nor is it known how such a process is normally controlled. It is possible that the colloid accumulates in the vesicles until sufficient pressure is reached to open up the communications with the lymphatics, or to rupture the vesicle and empty its contents into the surrounding connective-tissue spaces, and that the process may be facilitated by contraction of the muscles outside the gland. Such an explanation seems to me utterly inadequate.

Distension of the vesicles does not determine the escape of the colloid. In cases of parenchymatous goitre the vesicles distend enormously without emptying. In cases of acute inflammation the gland becomes depleted of colloid and the small vesicles are sometimes to be found empty when the larger ones are still distended. It is evident, therefore, that there must be some other method of absorption. There is no doubt that it is sometimes possible in cases of goitre with distension of the vesicles to trace a direct connexion between the colloid of the vesicles and the contents of the lymphatic spaces; such a condition, however, would seem to be an occasional accident rather than the normal process of absorption. In sections coagulated lymph closely resembles colloid, and is probably often mistaken for it.

The other explanation is that the colloid is absorbed by a method of diffusion through the walls of the capillaries. The blood-supply of the thyroid vesicles is analogous to that of the lung alveoli. The capillaries are very numerous and are in close apposition with the cells lining the vesicles. It is not uncommon to find capillary loops projecting into the lumina, also, to add to the analogy, the cells lining the vesicles are capable of phagocytic action and sometimes contain blood corpuscles and pigment. If we can assume that some substance, perhaps the internal secretion of another gland acting through the blood-stream, can render colloid

diffusible, we have a method by which the requirements for colloid absorption can be delicately adjusted. It has been suggested by Woolley[1] that the non-diffusible colloid is converted into a diffusible crystalloid.

In Graves's disease the changes in character of the vesicles—viz., the tubular structure, the infolding of the walls, and the high columnar epithelium—can be largely explained by an absence of distension. The glands, however, show indications of hypertrophy in that they are larger and more numerous. The excessive absorption of colloid can be explained by two factors, an increased diffusibility of the colloid and an increased blood-supply. The former is probably the more important.

In a previous paper[2] I pointed out that the changes in the thyroid gland in some cases of primary Graves's disease are focal in character. The distribution, to go back to the analogy of the lungs, is like that of a broncho-pneumonia. The areas affected vary from the size of miliary tubercles to nodules half an inch in diameter and larger. It is impossible to explain such a distribution of the changes by any theory which attributes the condition to alterations in the blood or nervous system, for it is evident that such alterations would affect the whole of the gland tissue or, at any rate, that of one lobe. We are left, therefore, with the explanation that at the centre of each of these foci there is some substance being formed which renders the colloid diffusible and possibly increases the blood-supply locally. Associated changes often found in the centre of these areas are lymphocytic and plasma-cell accumulation. In some cases these are slight, in others marked, and they are similar to the changes of chronic inflammation.

It is suggested that these points indicate an agent as the cause of Graves's disease which can lodge in capillaries and set up changes in the surrounding glands leading to absorption of colloid. The toxic action of such an agent must be slight. It is possibly a micro-organism. Other facts suggesting the same idea are the enlarged glands of the neck, the lymphocytosis, and the well-known fact that many cases of Graves's disease end with myxœdema. I have been endeavouring to test whether the gland in cases of Graves's disease contains a ferment which can render colloid diffusible. The experiments are not yet completed. The advisability of inoculating suitable animals—e.g., monkeys—with Graves's disease thyroid should be considered.

I am, Sir, yours faithfully,

HELEN CHAMBERS, M.D. Lond.,
Clinical Pathologist, Royal Free Hospital.

Feb. 24th, 1912.

To the Editor of THE LANCET.

SIR,—In your excellent abstract of the discussion on Partial Thyroidectomy and Local Anæsthesia (i.e., analgesia) my remarks on the employment of ether in such cases are not given quite correctly. May I extend your abstract?

I said that provided atropine was injected before ether was used, that anæsthetic was suitable for many of the cases. My experience with the open method of etherisation and of intravenous infusion of ether has led me to this conclusion, but as I pointed out the employment of ether by *any* method is open to one objection. The stimulation of the ether gives a spurious appearance of well-being to the patient whose real condition is thus masked. The operator may be misled and induced to undertake a more serious surgical procedure than he originally contemplated. The patient presents such a favourable aspect that even against his better judgment he continues his work, anxious as always to do the utmost for the patient.

When the ether administration is stopped collapse sets in and in some cases the patient cannot withstand the depression and sinks. If chloroform is employed in the way I suggest both the anæsthetist and the surgeon are better able to estimate the degree of operative shock, and the latter can restrict his procedures to the immediate necessities of the case. There should be no post-operative shock due to the anæsthetic unless over-dosage or asphyxial complications have been allowed to complicate the normal course of narcosis.

I am, Sir, yours faithfully,

DUDLEY W. BUXTON.

Mortimer-street, Cavendish-square, W., March 2nd, 1912.

THE PRESENT POSITION OF SALVARSAN.

To the Editor of THE LANCET.

SIR,—In view of the controversy at present raging as to the benefits to be expected from the arsenical treatment of syphilis one is forced to ask the question, Is it really as efficacious and curative in *the long run* as mercury and should we discard the latter drug as the routine treatment? I have had 29 years' experience of treating syphilis and conscientiously believe from the proved results of my treatment of many scores of cases which have been under my care from start to finish that when mercury is properly and adequately administered it will actually cure syphilis. I am in touch with many patients who were infected and treated years ago. I know them, their wives and children, and in a few instances the grandchildren. They are all free from any clinical signs of the disease and in those cases which have allowed a Wassermann to be done they have given negative results. My observations refer to patients who were infected from 15 to 40 years ago, or even longer. I think that one should be chary in expressing a dogmatic opinion upon the *cure* of a case of syphilis until time has assisted one to that end. When one knows from practical experience what can be done with mercury one does not feel inclined to entirely discard it in favour of another preparation which, regarded from the standpoint of time, cannot be said to have stood as lengthy a "curative" test. That arsenic is of undoubted value in certain cases there can be no question. But is it advisable to use it as a routine treatment, and can it be truthfully said to the patient that one will eradicate and cure syphilis by its use *alone*, or advise that it should be regarded as the premier drug?

In my experience one might almost say that there are two types of syphilis: that as seen in the better-class private patient, in contra-distinction to the disease as met with in hospital cases. I never see in private the gross ravages of the complaint which are so common in institutional clinics. Moreover, in the private cases after, certainly, six weeks' treatment it would be difficult for anyone to assure himself that the patient had got or had ever had syphilis, and if they will only follow out instructions they usually never have any further sign of the trouble. The hospital case, owing to loss of time in attending, which usually means loss of work and wages, is too frequently content to stop treatment with the disappearance of symptoms and does not seek further advice until a relapse compels it to do so. Their syphilis simmers within them. Mercury has received much unmerited blame, partly from the way it has been tendered and accepted. One meets with cases who complain that they have been under Mr. So-and-so's care for two years and are not yet well! Cross-examination reveals the fact that they may have visited the surgeon in question twice or thrice. They certainly have not accepted the proposed treatment or obeyed as regards alcoholic moderation. Consequently, they blame the surgeon and the drug. Again, I have had cases which were treated as syphilitic with mercury and no beneficial result ensued—for this reason, they were tubercle.

Certain cases of syphilis react magically to arsenic, whilst others do not respond satisfactorily. The same may be said of mercury. That arsenic does clear up certain specific lesions with remarkable rapidity is common knowledge. But mercury will do ditto. Hospital practice is one thing and private practice another. The better class, educated patient is apt to ask awkward questions and to want some guarantee as to the effect and results of proposed arsenical treatment. One of the usual questions is, Is it quite safe, no risk, danger, or ill after-effects? Well, I take it that such a question requires a "qualified" answer. The next is, Can you assure me that the effect of the injection will be a permanent cure and that the disease will not break out again? Of course, one must answer that query according to one's experience *and conscience*. We know but little about the propagation or multiplication of the spirochæte within the human body, whether it does so, for certain, by fission or sporulation. Certain microphotographs would lead one to presume fission, others sporulation. However much we know about the effect of arsenic or mercury on the mature spirochæte, I do not think we can speak otherwise than theoretically as to their action upon the presumed embryo, the subsequent maturation of which is conceivably the explanation of a "relapse." It has been suggested

that one should give one or two intravenous injections of arsenic so as to clear off the existing spirochætæ and then to follow up with a more or less prolonged mercurial *régime*. But if mercury is really necessary to effect a cure, why not start with it and continue with it to the final medication of the case, and not subject the patient to even the small percentage of risk which would seem to attend the intravenous injection of arsenic for what seems to me to be a transient and somewhat problematical benefit?

I have no hesitation in saying that mercury when adequately and judiciously administered cures syphilis. I would think twice before making such a dogmatic statement in regard to arsenic. It would now appear that aural symptoms are not uncommonly met with during the early stages of syphilis, or rather since arsenic commenced to displace mercury in the treatment of the disease. I would like to apologise to the many students to whom I have taught the rudiments of syphilis for not having mentioned this seemingly common symptom, for the simple reason that I was unaware that it occurred.

I am, Sir, yours faithfully,

March 4th, 1912. CAMPBELL WILLIAMS.

THE SIGNIFICANCE OF THE SYMPTOMS IN CASES OF DUODENAL ULCER.

To the Editor of THE LANCET.

SIR,—I desire to point out that the explanation put forward by Mr. C. Mansell Moullin in THE LANCET of March 2nd of the group of symptoms which he associates with duodenal ulcer is really no explanation at all, and incidentally to protest against the tone of his references to the views held by physicians on this subject. He says: "It is not consistent with scientific work to assume that a thing does not exist because it has not yet been seen," but it is at least as unscientific to assume that a thing does exist until it has been seen. His contribution to the problem is that the symptoms hunger-pain, pyloric spasm, hæmorrhages, and hyperchlorhydria are caused by an intensely hyperæmic and hyperæsthetic state of the mucous membrane, and in illustration of this he actually cites the case of the interior of the stomach of Alexis St. Martin.

The description to which he refers was given by Beaumont as follows: "The inner surface of the stomach showed extensive erythematous livid patches, from the surface of which exuded small drops of grumous blood, large and numerous aphthous ulcers, the whole covered with thick mucus"; but if I am not misrepresenting Mr. Mansell Moullin in supposing that this is the condition to which he refers the symptoms just related, it is noteworthy that Beaumont expressly states that St. Martin suffered no pain and had a good appetite, so that in the one case to which Mr. Mansell Moullin appeals in which the alleged condition was present there were no such symptoms as those for which it is now given as the suggested explanation.

I am not one of those who regard hyperchlorhydria as a satisfactory explanation of hunger-pain, but I protest against Mr. Mansell Moullin's language where he suggests that it is used by physicians as "a long word which hides our ignorance from our patients," followed by the remark that "the days of the early Victorian physician have not gone by yet," although I confess I do not understand what he means by that, except by using the words "early Victorian" in the contemptuous sense in which we hear this qualification applied to dress and furniture of that period which does not happen to satisfy the modern taste.

I suffered from hunger-pain for almost the whole of the first half of my life; it had no relation to "cold" or catching cold, I never had "jaundice," I never suffered from "septic poisoning," I certainly had it in childhood and up to the age of 35 or 40. It was distinctly brought on by fatigue and by excitement; for example, in my early manhood I always had a bad attack after making a speech; it was relieved by alcohol, a circumstance that I discovered on one occasion, but having a horror of such a remedy I never repeated it; I could always relieve it by a small dose of morphia; it was also relieved by a large meal, but not by a small one; in fact, small quantities of food seemed often to make it worse. I was undoubtedly neurasthenic and often suffered from overwork, and to this alone I attribute the symptom. I call it gastralgia for want of a better name, and I think it is possible that Soupault was right in attributing the actual mechanism to a spasm of the pylorus, but I have no doubt of its essentially nervous origin, and I have treated many cases successfully on the principles suggested by my own condition.

As one who has welcomed the assistance of surgeons and has fully admitted the great advance in the treatment of stomach diseases which has followed from that assistance, I regret that any surgeon should allow himself to adopt such an arrogant attitude towards his medical colleagues as is displayed by Mr. Mansell Moullin.

I am, Sir, yours faithfully,

Birmingham, March 4th, 1912. ROBERT SAUNDBY.

OPERATION FOR PHLEBITIS WITH THROMBOSIS.

To the Editor of THE LANCET.

SIR,—I have read with interest Mr. Skene Keith's communication in THE LANCET of Feb. 3rd *re* the excision of thrombi in cases of phlebitis of the superficial veins of the lower extremities. I have had several cases where this operation has been done with excellent results and greatly to the gratification of the patients. All that is necessary is to make a skin incision over the inflamed and thrombosed segment of vein, tie above first and then below the thrombus, and dissect out the intervening diseased part. This can be done *cito, tuto, et jucunde* under local anæsthesia, saving much time, relieving pain, and preventing all risk of embolism.

In "Clinical Memoranda" (Baillière, 1909) I have written the following paragraph:—

> The treatment of phlebitis and thrombosis of the veins of the lower extremities by the "masterly inactivity" of rest in bed, and local applications, is not only intensely irksome to the patient, but is fraught with the danger of sudden death from pulmonary embolism. All danger is averted by, and a speedy recovery follows, the surgical treatment by excision of the affected veins at the earliest opportunity. Moderate inflammation is no bar to operation.

I am, Sir, yours faithfully,

A. T. BRAND, M.D., C.M.

Driffield, East Yorks, Feb. 27th, 1912.

THE BEARING OF SIR DAVID SEMPLE'S TETANUS RESEARCHES ON SURGERY.

To the Editor of THE LANCET.

SIR,—I have lately been discussing with a number of surgeons Sir David Semple's researches on Tetanus,[1] and have been rather surprised to find that they do not consider them to have any practical bearing on surgery. They do not think that he has sufficiently proved his case to cause us to consider the matter from a practical point of view. If any of these men had been unfortunate enough to have had a case of tetanus ensuing on a surgical operation, as I have had myself on two occasions (hernia), or after a hypodermic administration of remedies, perhaps they would be more disposed to consider the matter. To my mind Sir David Semple has proved his case. It is a far-reaching case; I regard it as one of the most important papers of modern times in its bearing on surgery, especially in India, where tetanus is very prevalent. (In all that follows I am not referring to tetanus following mill injuries and such accidents.)

A few years ago there was considerable correspondence in the British medical press *re* tetanus following surgical operations, especially hernia. There was no definite conclusion arrived at as to the causation, but there was a very definite impression that some cases at least could not be explained by direct infection of the wound (through ligature or so forth). I am personally satisfied that Sir David Semple's paper, though not written directly to bear on surgery, demonstrates the proximal cause of tetanus following surgical operations where infection from direct sources can be excluded.

I have seen two cases of tetanus myself follow hernia operations; the same ligatures, the same lotions, &c., and technique were used for these cases as were used on the same day in several other major operations, including another hernia without tetanus following, and the same

[1] See Scientific Memoirs of the Government of India, No. 43 THE LANCET, June 10th, 1911, p. 1589.

has been used from year to year by me without seeing a case of tetanus following in anything else. Several other men whom I know have had the same experience. I also know of two cases of tetanus following ligature of piles by two other careful men. I know of a recent case of tetanus following the strangulation of a nævus on the face with a ligature by a careful man, and I also know of tetanus in a hysterectomy case in the British Isles by a very careful and experienced operator, where there seemed absolutely no possibility of direct infection. The fact that many men have never seen a case of tetanus follow a surgical operation or the subcutaneous administration of quinine, and that it is very far from often following either, is no argument that it does not follow. We can never tell when it may follow. One case is quite enough; is too many if it can be avoided. I once came across a brilliant young surgeon who was unfortunate enough to have had one such case, and was struck by the fact that the idea of it had ruined his nerve, not unlikely for life. There are enough cases of tetanus recorded, and crowds of cases unrecorded, following surgical operations to justify us in seriously considering its proximate causes.

As far as I can judge from my own personal experience and from the experience of others, both recorded and unrecorded, I believe that tetanus follows on operation for hernia very much more frequently than on any other. Up to the present time tetanus following operation has been put to the charge of the surgeon. The implication has been that he introduced the tetanus through suture, lotions, dressings, instruments, sponges, or from his own hands or those of his assistants—not a very comforting reflection for the surgeon. Why should this tetanus occur in spite of the utmost care on the part of the surgeon? I believe that the reason is explained by Sir David Semple's paper. An anaerobic area has been left—the *sine quâ non* for the development of tetanus from tetanus spores. Sir David Semple has shown that the spores of tetanus are frequently present in the human intestine. He has shown that when tetanus spores are injected into a given area of a guinea-pig and quinine injected into a distant area of the same guinea-pig, tetanus bacilli are to be found in the anaerobic slough produced by the quinine and nowhere else, and that a control guinea-pig which has similarly received an equal number of spores, but has not received any quinine, is not affected by tetanus.[2] How do the spores reach the anaerobic area in this case? I can only understand it by some of them travelling through the blood circuit and eventually becoming stranded in the area of dead anaerobic tissue, where they develop into toxin-producing tetanus bacilli. In the case of hernia the intestine, which may contain tetanus spores, has lain stationary in the hernial sac. May tetanus spores not migrate into that sac? The time-honoured operations for hernia imply a ligature of the sac, and excision of a portion of it distal to the ligature which leaves an anaerobic hernial stump. This may have in it migrated tetanus spores, or tetanus spores may be brought to it by the blood circuit. Since reading Sir David Semple's paper I have modified my treatment of the sac so as to avoid leaving an anaerobic stump. I draw down the sac, catch it as high up as possible with an intestinal forceps, cut it off below the forceps, fix a catgut suture at one end of the sac behind the forceps, and run a glover's suture from the fixed point through the sac and over the forceps, not tightening it until it is all inserted. I then open the forceps with the loose suture over them and insert a stout long probe between the blades and withdraw the forceps. With the assistance of the probe we can with a dissecting forceps draw the sutures tight, drawing out the probe as we go along. With the probe we put the stitches on the stretch, and hence we can find them easily to tighten them. I now return the stitched-up opening, and dispose of the opening in the abdominal wall in the usual way. This procedure is simple; it is as effective as any of the anaerobic stump methods, and it is an attempt to render tetanus after hernia as rare as it is after other surgical operations.

A ligatured pile is an anaerobic stump in the vicinity of tetanus spores. How are we to avoid tetanus in this case? Cut off the piles and stitch up the wound, or do a Whitehead's operation, or if we decide to ligature, then give the patient a dose of tetanus antitoxin. I have never had a case following piles, but I have only once ligatured a pile. It is not to be assumed that the policy which I advocate is a policy leading to laxity in our technique. A recent writer in the *Indian Medical Gazette* seemed to lament that the establishment of Sir David Semple's case would lead to this result. We have to deal with quite enough other germs to cause us to be as careful in our technique as if tetanus did not exist.

The records of my hospital show that tetanus frequently follows on mill injuries, often to all appearance injuries above suspicion. There are here on an average 20 to 30 such cases in the year. For over two years we have administered a dose of tetanus antitoxin to every such case on admission to hospital. There has been one case of tetanus developed in this hospital during these two years in such cases. That case came in nine days after the injury, and my assistant had used his judgment and considered antitoxin unnecessary, and hence did not use it. I add this paragraph to show the importance of the use of tetanus antitoxin as a preventive in such cases. As a curative agent, when symptoms of tetanus have developed, I have found it absolutely useless.—I am, Sir, yours faithfully,

HENRY SMITH, V.H.S.,
Amritsur, India, Feb. 15th, 1912. Lieutenant-Colonel, I.M.S.

[2] A growth of tetanus bacilli can be obtained by making anaerobic cultivation from the tissues at the seat of injection of the spores in both cases, and there is a growth of tetanus bacilli at the seat of injection of quinine in the quinine case.

THE COLOUR SENSE IN RELATION TO THE EMOTIONS.

To the Editor of THE LANCET.

SIR,—The effect upon the pulse-beat of a slight emotion may be illustrated from the examination of a candidate for admission to the railway service of New South Wales. The degree of emotion varies with the type of applicant. In one man there is great anxiety to obtain a position, in another comparative indifference to the result. One man is stable, another is neurotic. The degree of appeal in a railway fettler under examination for permanent employment in the railway service varies less than in any other class. This man belongs to a rapidly disappearing class, a large majority of whom were born and reared in the country districts by poor hard-working parents. They are as a rule big muscular healthy men of stable type, in many ways childlike, and more than usually honest. A neurotic railway fettler is rare. A casual observer would regard him as being mentally dull, but a true valuation is that within its limited orbit of observation and experience the mind is sound in judgment.

The appeal to a colour-blind fettler is direct to the mind, his face shows no indication of emotional response. This is very marked during his selection of the wools. When spoken to his voice is monotonous in tone, and still more so when attempting to name the colours in the lantern, when he frequently hesitates and pauses before answering. On the other hand, a fettler with a good colour sense never hesitates or pauses when he is naming the colours in the lantern; in his case there is no evidence that he requires assistance from the mind. During the examination by the wools the fettler with a normal colour sense frequently shows a slight degree of excitement, his hand may shake, and when examined physically there is frequently an increase in his pulse beat. This condition is transient and may disappear before the examination is finished. When the mind of a fettler realises that he has a defect which unfits him for the service he looks depressed, but if he is a colour-blind person there has been none of the preliminary excitement frequently seen in a person with a good colour sense. Under these conditions the depression appears to persist longer in a colour-blind person than in one with a keen colour sense, and to be more sombre and uniform in its mood.

One type of candidate drawn generally from the city is not satisfactory to deal with from the standard of emotional appeals. A number are neurotic, a class I endeavour to exclude from the running lines of the railway service. A dilated pupil, tremulous hand, rapid pulse, &c., frequently indicate the habits of a degenerate. A mind with experience will endeavour to exclude such persons.

I am, Sir, yours faithfully,

GEORGE HENRY TAYLOR,
Railway Medical Officer, New South Wales.
Sydney, Jan. 2nd, 1912.

THE INTESTINAL FLORA.

To the Editor of THE LANCET.

SIR,—Under the above title Dr. A. Distaso gives in your issue of Feb. 24th what he describes as a "brief summary of the results of my researches, the details of which will appear soon *in extenso*." I have been much interested of late years in the subject of the possible causation of some kinds of mental disorder, or of phases of such, through the absorption into the circulation of toxic material from the intestinal contents. I am therefore looking forward with interest to the detailed account of his researches which Dr. Distaso foreshadows. He will probably give in this the evidence for certain statements which appear in the summary just published. The inference from this observation is that he has as yet given no evidence for them; and this is precisely what I desire to affirm. I would call the attention of your readers, and of Dr. Distaso, to the following weighty statements which he makes without, in my judgment, adducing any evidence:—

> The flora of the normal adult ..... is certainly harmful, and, far from defending the organism against infection, it may be said to help it (*sic*).
>
> In the colon indol and other bodies belonging to the heterocyclic and aromatic series are elaborated and absorbed. These bodies, when absorbed, severely tax the functions of the body and therefore of the liver. This fact may throw some light on the etiology of diseases of the liver. [What "fact" is referred to?]
>
> Not only is there intoxication by the products of bacterial growth, but the disappearance of the bacteria indicates a process of autolysis, the products of which when absorbed cannot fail to be harmful.
>
> Constipation and the resulting intoxication are caused by the intestinal flora. [It is apparently taken for granted that all chemical changes in the intestinal contents which result in the production of toxin are due to bacteria.]
>
> Doubtless the products of the intestinal bacteria, by increasing secretions inhibiting the submucous plexuses, give rise to stasis.

I am, Sir, yours faithfully,

EDWIN GOODALL.

City of Cardiff Mental Hospital, Feb. 27th, 1912.

ELECTRIC METALLIC COLLOIDS AND THEIR THERAPEUTICAL APPLICATIONS.

To the Editor of THE LANCET.

SIR,—My attention has just been called to a communication in your issue of Feb. 3rd, over the signature of Mr. C. E. A. MacLeod, bearing on my article on the electric colloids of Jan. 13th.

Nothing was farther from my intention than to call in question the efficacy of the "collosols," and if I did not refer to them by name this was due to the fact that, as the writer himself admits, their introduction into therapeutics is so recent that sufficient time has not elapsed for it to have been possible to subject them to adequate clinical trial. The employment of colloids in therapeutics is by no means a new thing, for it is many years since the attention of the profession was first called thereto, and electrargol, with which most of my personal observations were made, has been tried on such an extensive scale that each one of its indications is established by a large number of published reports.

Then, too, as far as I can gather from the somewhat scanty references given by Mr. MacLeod, the "collosols" do not appear to have been employed for the same purposes as the electric colloids. As a matter of fact, the writer of the letter in question only mentions a certain number of local applications, and he barely touches the constitutional applications which have conquered for electrargol a place in contemporaneous therapeutics (pneumonia, broncho-pneumonia, influenza, suppurative infections, cholera, puerperal fever, eruptive fevers, &c.).

With regard to stability, I do not wish to call in question that of the "collosols," but this does not impugn the fact that the stability of the electric colloids has been practically demonstrated many years since. I mention this merely to show that in therapeutics each preparation must stand on its own merits, and must establish its own indications for use. The electric colloids have rendered great service to a large number of practitioners other than myself, but I feel justified in stating that the results obtained are their individual attributes, and in the absence of specific confirmation cannot safely be assumed to be possessed by other varieties of colloids. I am, Sir, yours faithfully,

Paris, Feb. 28th, 1912. B. G. DUHAMEL, M.D.

THE TREATMENT OF TUBERCULOSIS AND THE SANATORIUM QUESTION.

To the Editor of THE LANCET.

SIR,—It is a thousand pities that "F.R.C.P." should stir up strife in the medical profession by his remarks as to the constitution of the advisory committee on tuberculosis. Although one regrets the absence of certain names, every member of this committee is well known and distinguished for work done (and well done) in this department of preventive medicine; and the inclusion of a few more specialists or general practitioners would not have added appreciably to the strength of the committee.

From the remarks made by "F.R.C.P." on sanatoriums one would imagine that they were opposed to dispensaries instead of supplementing and completing their work. Even supposing that every case can be cured by tuberculin at a dispensary (which most authorities on tuberculin treatment would not admit) we still have to deal with the (mostly hygienic) causes leading to the tuberculous illness, which cannot often be done in working-class households without at least some training in a sanatorium. Example is always more powerful than precept, and the habits of a lifetime are more easily changed when the value of the change is demonstrated at a sanatorium. Moreover, no man in his senses would treat a febrile consumptive with tuberculin as an outpatient or in a working-class home if better conditions were available. It is the febrile consumptive who has to be treated as a rule, and no arrangements are adequate which leave this fact out of consideration.

Further, recovery from pulmonary tuberculous illness, *however treated*, is conditional; if habits and conditions of life are unsatisfactory relapse or reinfection usually takes place sooner or later. Not every tuberculous person needs treatment. Many such go through life without tuberculous illness; but if a tuberculous person has more than a very limited quiescent lesion, if the bodily health is in any way affected by the tuberculous focus, and if his habits or conditions of life are unsatisfactory, he is in danger of a breakdown and requires treatment, directed not only against the tubercle as such, but against all other contributory causes. We need open-air schools, training in domestic hygiene, better housing, early diagnosis based upon physical examination in addition to the tuberculin test, systematic treatment by hygienic means as well as by tuberculin and other remedies, and adequate measures for after-care in the shape of hygienic homes, day and night camps, and the like. For such a programme we need the open-air school, the dispensary, the sanatorium, hospital, or home, the health colony or camp; and we need them all. I am, Sir, yours faithfully,

Farnham, March 2nd, 1912. F. R. WALTERS.

CYSTITIS AND URINARY ANTISEPTICS.

To the Editor of THE LANCET.

SIR,—I have been much interested in the two exceedingly able and full articles on "Cystitis" by Dr. David Newman which have appeared in your recent issues. There are, however, certain small points with reference to the action of urinary antiseptics in the second paper on treatment, which are so entirely at variance with the conclusions that I have formed on the matter that I cannot forbear criticism. I have been doing experimental work on this subject for some time (the results of much of which will be found in the *Bio-Chemical Journal*, Vol. V., Nos. 6 and 7, and in the most recent Transactions of the Section of Pharmacology of the Royal Society of Medicine), and this is my excuse for discussing a subject where Dr. Newman's clinical experience is so incomparably greater than mine. Dr. Newman states, in referring to the giving of urotropine and helmitol in cases of mild B. coli infections, that "in cases where the urine is acid, as in B. coli infections, formalin is liberated from these preparations and creates irritation, but if the urine be rendered neutral or alkaline by potash or lithia salts this difficulty is overcome." These words appear to me to imply that Dr. Newman considers that the liberation of formaldehyde by acid urine from urotropine is in the nature of an incident, not desirable in itself, and which it may be desirable to prevent. As a matter of fact, there is, I think,

not the slightest doubt that these drugs act slowly by the liberation of formaldehyde and are not in themselves antiseptic. This liberation, as Dr. Newman says, only takes place in an acid medium, and, in consequence, to render the urine alkaline is to render urotropine or helmitol of no effect, and they may just as well not be given. Further on, under the heading "Chronic Cystitis," the statement is made: "When the urine is acid, alkalies and alkaline salts are indicated." This is a generalisation of the statement, so often made, that in B. coli infections the urine should be rendered alkaline, because alkaline urine inhibits organisms of this class. This inhibitory power exists, but it is comparatively slight and is negligible compared with the very great antiseptic power against B. coli of an acid urine *plus* urotropine, so that I am decidedly of opinion that in these infections the aim should be to increase the urinary acidity as much as can be tolerated by the patient giving urotropine in conjunction; and, in the few cases in which I have been able to apply this principle, the results have borne it out. In conclusion, I should like to say how pleased I have been to read Dr. Newman's praise of boric acid given by the mouth as a urinary antiseptic, since I have found that in laboratory experiments, at any rate, it is quite efficient, and is, indeed, the only efficient drug in alkaline urine, while its use as a urinary antiseptic at all is by no means generally recognised.

I am, Sir, yours faithfully,

ANSON JORDAN, M.D., F.R.C.S.

Cambridge, March 5th, 1912.

ANCIENT EGYPTIAN SPECIALISTS.

To the Editor of THE LANCET.

SIR,—In an interesting annotation in this week's LANCET entitled "The Story of Ancient Medicine revealed by Greek Inscriptions," you say quite rightly: "The life-history of the ancients can no longer be adequately written by confining research to the classic authors." I am not sure, however, that even these writers have been completely exhausted. Take, for instance, the side-light which Herodotus, the father of history, throws casually on the above subject in his history of the Persian war: ἡ δε ἰητρικὴ κατὰ τάδε σφι δέδασται· μιῆς νούσου ἕκαστος ἰητρός ἐστι καὶ οὐ πλεόνων. πάντα δ' ἰητρῶν ἐστι πλέα· οἱ μὲν γάρ ὀφθαλμῶν ἰητροὶ κατεστέασι, οἱ δὲ κεφαλῆς, οἱ δὲ ὀδόντων, οἱ δὲ τών κατὰ νηδύν, οἱ δὲ τῶν ἀφανέων νούσων (B, 84).

I particularly appreciate those experts τῶν ἀφανέων νούσων. I wonder what diagnoses they made!

I am, Sir, yours faithfully,

Hove, March 2nd, 1912. W. AINSLIE HOLLIS.

MEDICAL MEN AND CERTIFICATES: A TEST CASE.

To the Editor of THE LANCET.

SIR,—A test case which I recently took into the petty sessions at Petersfield, and won, may prove of interest to the medical profession. A child of poor parents was under my care for some months and was unfit to attend school. The education authority demanded a medical certificate. Now I maintain that such certificates have a certain value, and therefore either the authority or the parents must pay for them. But one cannot ask the parents to pay, at any rate in these poor agricultural districts. So I always refuse a certificate unless the authority will pay a fee, and have steadily done so for the nine years I have been in practice. Of course, I originally ascertained that legally the authority had not the power to insist on a certificate; and for nine years they have not attempted to prosecute in these circumstances. This time, however, they did. I had persuaded the parents to let me see the case through at my own expense. I instructed a solicitor, Mr. Percy Burley, of Petersfield, and gave evidence myself, and the education authority had no case at all, although the magistrates could not see their way to grant any costs. The attendance officer who prosecuted owned that he was told by his superiors at Winchester to go right through with the matter because they knew it was practically a test case. I carried it through as a question of principle. We medical men, in the country at any rate, are expected to write certificates for school boards, juries, &c., without fee, and often without the barest thanks.

I am, Sir, yours faithfully,

East Meon, Hants, March 2nd, 1912. EDWARD T. JONES.

COMPULSORY NECROPSIES.

To the Editor of THE LANCET.

SIR,—The time is rapidly coming when no practitioner should be allowed to certify a "cause of death" not verified by post-mortem examination. The Insurance Act will spend millions on the prevention of untimely death—but we really do not know what people die of. I am an ordinary practitioner; I find I have signed in my time about 1200 certificates of "cause of death," yet not in a dozen cases was there a necropsy, and I may have been mistaken 90 per cent. of the times.

Now the Registrar-General's returns of the "causes of death" are simply made up of my cases and the similar cases of other practitioners possibly more ignorant than myself. Of what scientific value can they be?

I am, Sir, yours faithfully,

J. C. MCWALTER, M.A., LL.B., D.P.H.

Dublin, March 4th, 1912.

THE WORK OF A MEDICAL MISSIONARY IN CHINA.

(FROM A CORRESPONDENT.)

AT the request of the special correspondent of THE LANCET in China I am permitted to give a very rough sketch of the work of a single medical missionary from the professional point of view only. It is the rule of the Church Missionary Society to station at least two medical missionaries at each station; unfortunately, the supply does not keep pace with the demand, and during the last six years, to which the following brief notes apply, I have been alone professionally with but few exceptions. In this statement I do not refer to those Chinese assistants who are able to do some parts of the manifold variety of duties connected with the carrying on of a hospital of some 60 beds, annually treating some 600 in-patients and 11,000 out-patients, male and female.

Nature of Work.

In this connexion I would deprecate the idea that statistics convey a real idea of the quality of the work done; they may become a source of real danger to medical missionaries, and the public who support this sort of work are to some extent responsible when they compare one set of figures with another, not knowing the circumstances under which work is done. For example, one man (with great self-control) confined his first few years in the work to the surgery of circumcisions, sebaceous cysts, and the like; the result was an infinitesimal death-rate and the object at which he aimed, the confidence of the Chinese. Another to my intimate knowledge has never refused to operate upon any case brought to him with any hope of cure; and many a sigh of private professional relief has he breathed when even this "fighting chance" has been refused; but the death-rates of the two surgeons should not be compared.

Considering this small hospital at Ningpo as a type of many, the class of work done will show to friends at home the importance of having an all-round training and the faculty of adaptability. One has to try to combine the offices of surgeon and physician, general practitioner and consultant, pathologist and bacteriologist, X ray expert and general mechanician when apparatus breaks down, general superintendent and ofttimes nurse, architect, and builder; and added to these usually the duty falls to one of trying to raise the money with which to carry on the work of helping the helpless.

Many a practitioner at home struggling against competition may well envy the medical missionary with his sphere of work. In these few remarks I shall confine myself as far as possible to the surgical aspects of our mission work, and I trust that no one will misunderstand when the other side of our Divine commission, "to preach the good news and heal the sick," is passed over in this article.

During the past six years, then, approximately there have been 3400 in-patients and 59,000 out-patients. Operations under general anæsthesia more than 1100. Minor operations under cocaine, eucaine, &c., eye operations more than 1400.

Malignant Disease (52 Cases).

Of these 52 cases, 42 were confirmed by microscopic sections; 28 were epiblastic in origin and 24 mesoblastic; 28 were in males, 24 in females. Three were fatal whilst in the wards, in each case put down to shock of operation—(*a*) sarcoma of the kidney, female, aged 46; weight, 6½ lb.; (*b*) fibro-sarcoma of the uterus, female, aged 39; weight, 20 lb.; (*c*) osteo-sarcoma of the rib, male, aged 51; weight, 8 lb.

Malignant disease in our practice means that the patient has gone the round of the native doctors, each of whom has probably guaranteed a cure for varying sums of money, and in addition probably the local deities have been called upon to assist—again for a monetary consideration to the priests. Finally, when ulceration or glandular infection has set in, the foreign doctor is consulted.

In this connexion I might mention that there is one particular shrine near Ningpo to which patients are taken, and so far as I have gathered from the Chinese its chief claim for distinction lies in the fact that several hundred years ago a celebrated physician lived there who took more liquor than was good for him, and in that condition he fell into a pond and was drowned. Hence the sanctity and healing virtue of the shrine.

Our oldest case was 84, with squamous-celled epithelioma of cheek, and the youngest 7, with mixed-celled sarcoma of lower jaw. Like others at home, we have experienced the pleasure of seeing an inoperable, clinically and microscopically, malignant tumour disappear. The patient was a middle-aged woman, and the whole of the lower half of the abdomen was occupied by a solid tumour, which on opening the peritoneal cavity was found to have invaded almost every organ in the neighbourhood, and even the abdominal wall could be seen to be infiltrated by the growth. The actual original focus I could not settle, but it seemed to spring from the left uterine appendages. I sutured the abdominal wall, and explained that the tumour could not be removed, and that there was no hope of recovery. Sections of the growth invading the abdominal wall were made, and were thought to be endotheliomatous. From the day of operation improvement set in, and all the classical symptoms pointing to presence of malignant disease disappeared. When seen nine months later only a slight thickening in the left iliac fossa was palpable, and five years later she was still quite well.

One of my early cases of malignant disease (*not* included in statistics) was a cat, aged 17, the faithful friend of a clerical colleague. After removing a typical carcinomatous breast recurrence followed, and I was impelled to destroy it. My Chinese assistants could not understand our desire to save the life of a beast. Since, then, however, we have been consulted in the matter of both dogs and cows!

Amputations (125).

These are, unfortunately, common. When foreign fashions, such as railway travelling, come in these will be immensely increased. Utter carelessness is the feature of those in the local cotton mills; no factory precautions are enforced—they have not yet been thought necessary. One man was brought to us with an arm almost severed, and not any attempt at first aid had been given; he died before we could do anything, having been bleeding probably quite an hour. Total number of amputations, 125. Of these, 1 through hip-joint, 11 through the thigh, and more than 40 through different parts of the leg or foot. Amputations of the upper extremity, 11.

Several times *double* amputations were performed, in no case fatal. In one case of double gangrene in a woman with advanced cardiac and renal disease, and a history of lingering agony with battalions of blue-bottle larvæ occupying every position in the gangrenous limbs, we felt that there might be some slight hope in amputation if the anæsthetic were possible. We have had no experience of spinal analgesia, and so, after injecting 1 c.c. of Burroughs, Wellcome, and Co.'s pituitary gland extract, we amputated both legs through the knee-joint; including anæsthetising, operating, and bandaging we spent just 20 minutes, my Chinese colleague completing his work about a minute before I did. However, his flaps in the end continued to discharge serous fluid long after mine had healed. In this case I used the opportunity of a control amputation by my Chinese colleague (under the usual precautions of a thorough hand cleansing) and deliberately omitted to wash *my* hands. I immersed them for ten minutes in biniodide of mercury in rectified spirit 1 in 1000. The woman made a good recovery, and the occasionally marvellous effect of pituitary gland injections in combating shock was shown by the fact that the pulse was far better after than before the double amputation under chloroform—our routine anæsthetic.

Of cases urgently needing amputation quite as many patients refuse as consent to undergo an operation' probably more; the reason alleged is that in the spirit world the absence of a limb is a terrible calamity. It is for a similar reason that to be decapitated is reckoned by Chinese a far more severe punishment than all others, but even this may be got over (like most things in China) for an expenditure of money. In the neighbourhood of Ningpo a powerful and rich man some hundreds of years ago displeased the Emperor, was beheaded, and was buried; but the relatives made some *ten* huge graves, killing off thousands of stonemasons to preserve the secret as to which of the ten was the one occupied by the unfortunate man without a head, the reason being that (it is said) a false head of pure gold was fixed up, which would certainly deceive everyone in the spirit world, just as surely as gold works wonders in this present age.

Bone Operations (197).

Excisions of hip joint 3, elbow 5, shoulder 2, maxillary articulation 2. Necrosis of bone is one of the commonest surgical complaints in this part of China; the lower end of the femur very common.

Hæmorrhoids, Fistula in Ano, &c. (127).

Clamp and cautery the routine treatment, though occasionally Whitehead's operation, especially useful in cases of prolapse of rectum of many years' standing, such as would seldom be seen at home. We use the "locking up" of the bowels method, so emphatically condemned by some, but none the less efficacious in our experience; a morphia (½ gr.) suppository is always inserted after operation, and the third day a saline purge is given.

Eye Operations (Iridectomies, 44; Cataracts, 17; Excisions of Eye, 12; Hypopyon, 11).

It is remarkable to note the comparative infrequency of cataract operations as seen in *this* part of China.

Operations for entropion and ectropion average some 40 per annum. The Streatfield-Snellen operation is the one preferred. One feature of excision of the eyeball is absent in similar cases at home; I refer to the public handing over of the eye to the immediate relatives of the patient. So many wild rumours are in constant circulation, that to show the credulous Chinese that we do not make medicine of the eyes of our patients we always return them their property in full view of all, but still, probably, they will credit us with the practice.

Gynæcological.

The less said about this branch of the work the better. We are scarcely ever called in till decomposition of the fœtus is in progress, the old women midwives having done their worst. We do not make a feature of this work, but out of 64 cases it is interesting to note that *only 14 were normal.* There were 6 maternal deaths. There were 11 cases of transverse presentation with either tonic contraction of the uterus or septic decomposition of the contents; of these 1 child only was saved. Decapitation is usually our procedure, but so far from it being easy we have found it extremely difficult, so acute is the flexion of the child and so firm the grip of the uterine muscle. Usually for days after such a case one's fingers have but small power.

There were 4 cases of eclampsia, 3 of placenta prævia, 1 of hydrocephalus, 1 of face and 1 of unreduced occipito-posterior presentation. Chinese midwifery as we have met it is awful in its simplicity; it consists usually in letting the patient die if normal delivery is not possible. One case treated in our wards was that of a woman from whose uterus we removed the remains of an "aftercoming head" 38 days after the remainder of the body had been wrenched away by Chinese midwives; the base had disappeared but the remainder was removed and the patient recovered rapidly.

Glands of Neck, Axilla, &c. (89 Cases).

To get a case before suppuration and periadenitis has set in is not common. Hence the operation usually is one requiring long dissection and deep.

Abdominal Sections (34, with 9 Deaths).

These are rare events in China so far. Before the period in which these occurred, only one, I believe, had been performed in this city of 400,000 inhabitants, and it should be noted that 7 were done during the first three years and 27 during the last three. Refusals of leave to operate are almost daily met. Liver abscesses were 7, 4 amœbic and 3 mixed infections. Spleen abscesses were 2, both staphylococcal.

In these cases I have used siphon-drainage habitually, an interrupted rubber drainage-tube passing into a vessel under the bed containing a measured amount of 1 in 40 carbolic acid lotion. The benefit to both patient and surgeon is enormous; the value of Leonard Rogers's work on this subject is very great. Two features strike me as of importance in this matter: the surgeon knows just how much pus is passing out and when blocking occurs, and the patient is convinced (though in suspicious China) that there was some necessity for the operation after all, seeing the daily siphonage of pus. Of the value of the method towards keeping the cavity in the liver sterile no one should need convincing. Two cases were fatal, both from complications. The largest amount removed was 140 ounces from the right lobe of the only woman patient I have treated for this condition. She was, with one exception only, the most morose and suspicious patient I have met, but six months after operation she came to see me an utterly different woman, physically and mentally and morally.

In these few years the feeling of the Chinese that the abdomen was not meant for the surgeon has been passing away, but probably few surgeons at home can point to a consecutive series of seven advanced ovarian cysts in one year, each refusing to allow operation. The commonest condition I have met is that of fæcal fistulæ, generally the result of strangulated herniæ; occasionally with a traumatic origin, as in one case where a bullet smashed up the last few ribs and ploughed a furrow in the splenic flexure of the colon, leading to a chronic fæcal fistula which showed no tendency to close. The colon was found to have a fair mesentery and was sutured successfully.

A thing which has struck me as unusual is the frequency of chronic intussusception in the adult; whether diet enters into its causation I cannot say. The symptoms sometimes seem to be very slightly marked except in the later stages, and in one case quite recently we watched the tumour migrate successively from the right iliac fossa to the hepatic region and onwards. The case was typical, but the patient refused permission to operate. The same sad features occurred in another more acute case, when the tumour was actually seen to project from the anus; the patient died a few days later. One woman allowed me to do an abdominal section for this condition, and it was of the cæco-colic variety. Reduction was possible and a tumour of the caput cæci was found and removed together with the appendix and portion of the cæcum. She recovered rapidly. The tumour was of the size of half a walnut roughly, and was non-malignant. This patient was very strong-minded, desiring surgical help against the wishes of her relatives.

Ovarian tumours are commonly met, and only three have been removed—two ordinary multiloculars and one dermoid complicated with an abscess in the broad ligament containing gonococci. This last case died from lobar pneumonia on the third day, with no abdominal symptoms. Only three appendix cases have been operated upon out of the three or four met yearly. The comparative rarity in Ningpo seems striking. Two of these three had abscesses and the third was a case of advanced gangrene; the latter died.

One of the most interesting from a bacteriological standpoint was an abdominal abscess caused by a streptothrix of an unknown variety. It probably commenced in the appendix region, and was opened in the left iliac fossa. The case was published at the time in the *China Medical Journal*.

Other Operations.

Miscellaneous operations included three upon the œsophagus in two of which X rays were of great help in localising. A Chinese-made false tooth-plate with one tooth, and numerous jagged edges, was swallowed during sleep by a man. We did a tracheotomy to relieve dyspnœa, and finally cut down on to the œsophagus between the left lobe of the thyroid and the sterno-mastoid and removed it entire. The material of which it was made and the fact that ulceration was present might have made removal by the mouth impossible except by experts. In any case both this and the case of a long needle swallowed in the rice bowl recovered. The third was a lad with an œsophageal fistula about an inch above the clavicular insertion of the sterno-mastoid. Possibly this was congenital in origin, as he had had it as long as he could remember. Milk taken by the mouth flowed out at once. We excised about 1½ inches and ligatured the remaining portion with catgut, and it healed over at once.

One dorsal laminectomy for tubercular disease causing sudden paraplegia in a young man gave great benefit, but only for a few weeks. Incidentally we may mention that the patient ripped off all his dressings the day after operation, and the wound was caused to gape open.

In our work we must not be surprised at meeting strange experiences. One excision of the breast for carcinoma comes to my memory when I actually found the woman expectorating on to the lines of suture, having taken off the dressings. The case healed by first intention, but hardly in consequence of the extra lavage.

Elephantiasis is of very common occurrence amongst the "farm labourers," and in two instances I have done Handley's operation of lymphangioplasty. The effect on the first was marvellous in the diminution of the hypertrophied tissues and the healing of a huge chronic ulcer, but I am bound to say that from this limited experience I am not a believer in its value for elephantoid legs in Chinese coolies. The value of the operation will probably be found when gravity assists rather than hinders the capillary action of the embedded silk threads. Whether the great amount of elephantiasis in this region and the comparative *absence* of filariasis in the general population are related to one another in any way needs to be worked out. In 120 consecutive examinations of night-taken blood from hospital patients (20 c.mm.) the filaria was found in but one, and he came from a place 200 miles to the south of us.

No less than seven cases of congenital absence of the anus were seen, the eldest being five days old. Every single one was a male, and the reason for the sex being so uniform is suggested by the remark of one parent, "If it were not a boy we would not have troubled to bring him." Infanticide of girls is not yet a thing of the past in some parts of China. We saw eight cases of cancrum oris, all fatal, and usually seen when the cheek has been extensively destroyed. The bacteriology is not yet clear. Arguing by analogy from two cases recently seen, the possibility of a spirillar origin with other organisms living symbiotically should be investigated. Vincent's fuso-spirillar symbiosis I have demonstrated in two cases, one of recurring gangrene of the toes, and one a peculiar subacute gangrene of the penis, *not* syphilitic in origin in all probability. Gunshot wounds call for no special mention, but the variety of missiles in shape and material is fairly great. A large portion of our work consists in trying to undo the effects of the surgery of the Chinese; in particular the use of a septic needle habitually plunged into anatomical situations, usually considered dangerous by us from the West, gives us plenty of septic joints, for example. The knee-joint on four occasions was certainly thus infected, and in five others almost certainly so.

There should be a great future before vaccine therapy, for the average Chinaman most certainly believes in the needle. A mere catalogue of one's surgical operations in a small hospital is of slight value in itself, but this account has been written with the hope that, the work of the ordinary medical missionary being of a varied and somewhat important nature from the physical aspect alone, the sympathy of one's professional brethren at home may be possible; and this can only be when they realise the nature of our work, such as these brief notes have aimed at giving.

KING'S COLLEGE HOSPITAL.—At the annual court of the corporation, held on Feb. 29th, Mr. Herbert Haynes Twining was elected treasurer of the hospital in succession to Mr. Charles Awdry.

PLAGUE IN RUSSIA AND THE NEAR EAST.

(FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

Plague in the Kirghiz Steppes.

THE centres of endemic plague in the southern steppes of Russia, Asiatic and European, continue to show considerable activity. The published records of the different outbreaks are incomplete, but from paragraphs appearing in the Russian medical journals and from communications made by the Russian delegate to the Constantinople Board of Health the following facts may be gathered. During the latter portion of the year 1911 plague outbreaks of greater or less extent occurred in various Kirghiz settlements in the governments of Astrakhan, Uralsk, and Semirétchinsk. The area covered by these three governments is a very large one; the latter two are in Asia and the first is in Europe. It is particularly in the steppes of the Astrakhan government that plague has recently been most active; in the other two it has been confined to few and relatively small outbreaks.

In the Semirétchinsk government, which is situated close to the Mongolian frontier and to the north of Kashgar, plague appeared on August 31st (Old Style) in the *urotchishché* (Kirghiz settlement) of Akskoé, in the *volost* of Tcherikof. By Sept. 4th there had been 4 cases, all fatal, of pneumonic plague. A later telegram, from Prjevalsk, dated Sept. 14th, reported 8 fatal cases of the same disease in the above-mentioned *volost*, at a spot near Naryn (in the Prjevalsk district of the Atbashinsk region); it is probable that this was one and the same epidemic. Two more deaths occurred here on Sept. 16th, including that of a mollah who had washed and buried the bodies of some of the earlier victims. By Sept. 20th the epidemic here was declared to be at an end.

In the Uralsk government, situated much more to the west and adjoining the Astrakhan government, 5 deaths from pneumonic plague occurred in the Uletinsk *volost* before August 10th. In the same district, in the "9th *aoul*" (or Turkoman settlement), near Djambent, 8 fatal cases of pneumonic plague were recorded between June 29th and August 8th. In the Tchadyrtinsk *volost* of the same government 8 cases and 3 deaths from plague of the "pneumonic and abdominal forms" occurred before Sept. 10th, followed by 1 death on the 12th and 1 fatal case on the 13th. Another case occurred in another settlement 5 versts away, and the totals by Sept. 16th had reached 10 cases and 6 deaths.

In the Astrakhan government plague was epidemic in the *urotchishché* of Saganai from the end of August to the middle of September; a score or more cases occurred here. On Sept. 21st the disease became epidemic in several other centres. The following table is a summary of the later returns:—

Period.	No. of infected centres.	Cases.	Deaths.
Sept. 21st to Nov. 7th	16	73	63
,, ,, ,, ,, 21st	28	120	102
,, ,, ,, ,, 28th	33	139	119
,, ,, ,, Dec. 19th	38	187	166
,, ,, ,, ,, 26th	43	201	180

The infected centres were situated principally, if not entirely, in the Narynsk, the Kamysh-Samara, and the Primorskais (or maritime) divisions of the Astrakhan steppes. The disease was most active in the Ak-tchagyl settlement (15 versts from the above-named Saganai), and in those of Sartubć, Kudanysh, Djapalatka, and Antan-tchagyl. Elsewhere but few cases or deaths occurred in any single centre. While many of the outbreaks were pneumonic in character, this was not invariably the case.

In the Russian medical journal, the *Vratch*, No. 35, of August 27th last, an article of considerable interest upon plague in the Kirghiz steppes was published by Dr. Koltsof, a member of the medical mission sent by the Russian Government last summer to deal with these outbreaks. The article is mainly confined to an account of the epidemic occurring in the steppes between May 6th and July 19th of last year, when 33 cases and 32 deaths from plague were recorded in 9 centres; but it also contains a summary of the epidemics in the Bukeëf Horde of the Kirghiz steppes of the Astrakhan government during the preceding 12 years. The summary is limited to this particular region of the steppes. It may be held to supplement the list of epidemics given in my article upon "Some Hitherto Unknown Centres of Epidemic Plague in the Kirghiz Steppes," published in THE LANCET of April 24th, 1909. According to Dr. Koltsof's observations, the disease generally, but not always, gives rise to two annual epidemics in the infected centres, one in summer the other in winter. Working backwards from last year, he finds the following outbreaks recorded.

In 1910 the winter epidemic ended on Feb. 22nd, and the summer one began on June 15th. In 1909 there was no summer outbreak; the winter outbreak began at the end of October, and continued until February, 1910. In 1908 there was only a summer epidemic, lasting from July 7th to August 3rd. In 1907 the summer epidemic began on July 26th, the winter one on Oct. 11th. In 1906 the winter outbreak ended on Feb. 28th, and the summer revival of the disease on April 15th. In 1905 occurred the exceptionally severe epidemic known as the "Beketaieff epidemic," in which some thousand persons lost their lives; it began on Oct. 13th and continued until February, 1906. Some minor outbreaks also seem to have occurred in the summer of 1905. In 1904, when plague was prevalent among the Kirghiz and Cossacks in the Uralsk province, it was imported thence to the Bukeëf Horde in December, but caused only a limited outbreak. (It is stated that 415 persons died from the disease in the Uralsk province.) In 1903 there was apparently no plague in the Horde, though it was epidemic elsewhere in the Astrakhan government. In 1902 there was only a summer outbreak, beginning on June 3rd. In 1901 there was no summer epidemic; the winter epidemic of 1900–01 began on Dec. 23rd and is known as the Tekebai-Tubek epidemic. No summer revival of plague occurred in the summers of 1899 or 1900; but in the winter of 1899–1900 there was an epidemic, which began on Nov. 15th. Beyond this date there are said to be no records of plague in the Bukeëf Horde. The article contains observations upon the epidemiological, clinical, and post-mortem characters of plague in these regions, and on the measures taken to suppress the outbreaks.

In another article published in the *Vratch*, No. 52, of Dec. 31st, 1911, M. Shurupof, a veterinary surgeon, records some observations upon the possibility of plague occurring in camels. Attention had already been called to this possibility, and some of the above plague outbreaks in man were said to have been accompanied by a disease in camels. In one of the cases at Saganai the attack was said to have followed the consumption by the patient of the flesh of a camel that had died from that disease, and it was added that Dr. Klodnitski, a bacteriologist, had found the plague bacillus in the camel's tissues. The importance of such an observation, if confirmed, is obvious, and the Government has sent a veterinary specialist to the steppes to make further investigations. (See the *Vratch*, No. 42, of Oct. 15th, p. 1630). M. Shurupof's experiments were carried out in the laboratory in Fort Alexander I. at Cronstadt, as far back as 1902, with the object of obtaining a protective serum from these animals. But although three animals were injected intravenously with relatively enormous quantities of plague cultures, none of them took the disease. It is concluded that these animals are entirely insusceptible to plague. A similar experiment, made on a single camel in the same laboratory in 1898, had led to the same negative result. The writer of the article thinks that the recent observations above referred to made in the Kirghiz steppes must be received with doubt, and that possibly the organism isolated from the dead camel by Dr. Klodnitski and others was the Bacillus bipolaris plurisepticus, and not the plague bacillus.

It should be noted that all dates mentioned in the above paragraphs are according to the Old Style.

Plague in Odessa.

Four cases of plague occurred in Odessa late in September and early in October last (Old Style). None have been reported since.

Plague in Smyrna.

On Sept. 17th a fatal case of plague was seen in Smyrna. The patient was a porter connected with the German post-office in that city. He had arrived from Koniah three weeks before. On Sept. 22nd a second case was seen, in another

employee of the same post-office. In neither case was the source of infection known.

Plague in Mersina.

A single case of plague occurred in Mersina on Nov. 5th. The patient was a *kavass*, aged 24; he died on the 8th. Here also the origin of the infection could not be traced.

Plague in Jeddah.

The annual revival of plague in Jeddah appears to have begun on Jan. 13th, when a single case was seen in a native servant. A second case followed on the 15th. No fresh case was seen until the 31st, when 3 deaths were reported, followed by a fresh case on Feb. 2nd. No case has been reported since. Yanbo and El Wej have both remained free from the disease.

Constantinople, Feb. 12th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Health of Birmingham.

THE health committee in reporting upon the health statistics for 1911 points out the difficulty of comparison owing to the extension of boundaries. The committee, therefore, deals with the figures relating to the city as constituted prior to Nov. 9th. The death-rate for the year was 16·8 per 1000. In the three previous years it was 14·8, 16·6, and 16·9. The higher figure last year was due to the excessive rate in the summer months. Although the summer was the hottest on record the diarrhœal mortality was lower than in some previous years. It was 1·37 per 1000, whereas in 1906 it was 1·64, and in 1904 1·83. The special efforts made in recent years to lessen the diarrhœal death-rate and infant mortality have evidently met with some success.

Birmingham and Consumption.

The mortality from tuberculosis shows a substantial decrease when compared with the mortality during the previous ten years, the number of deaths being 1490, as compared with the average for ten years of 1771. At Salterley Grange, where early cases only are treated, there was arrest of the disease in almost all the 116 patients discharged. Much good has also been done with the more advanced cases admitted at Yardley-road Sanatorium, where patients are taken for six weeks' educational treatment. Tuberculin is administered to these patients by the intensive method, and the treatment is continued afterwards in a special dispensary for as long as necessary. The sanatorium accommodates 60 patients, and it frequently happens that everyone is receiving tuberculin. About 300 inoculations a week are given in connexion with the sanatorium and dispensary, and the Birmingham system of giving a short period of sanatorium treatment, combined with tuberculin, merits attention from the authorities concerned with the administration of the money set apart for the treatment of consumption under the Insurance Act.

A New Obstetrical and Gynæcological Society.

For some months there has been an effort to form an Obstetrical and Gynæcological Society for the Midland and Western Counties. It has been strongly felt that a society should be formed on lines similar to those already existing in London, Glasgow, Edinburgh, and the North of England. A meeting was held on Feb. 19th which was largely attended not only by local specialists but by delegates from Bristol, Cardiff, Lincoln, and Woodhall Spa, and a society was formed with Professor Edward Malins as president.

The Children's Hospital.

The annual report shows that 15,612 patients were treated during 1911, as compared with 15,261 in 1910. The average cost per person maintained in the hospital was 4*s.* 2*d.* per week, as compared with 3*s.* 11*d.* in 1910. The year had been occupied with the development of the plans for the new hospital. The committee had at call for building and furnishing about £35,000, but it was anticipated that a further £15,000 would be required.

The University of Birmingham.

The annual report presented at the annual meeting of governors on Feb. 28th shows that 1017 students attended the University last session, of which number 633 were matriculated students. The number of matriculated medical students was 85, the largest number since 1904, when it reached 92. The total number of medical students matriculated and not matriculated was 200, of whom 45 were women. The chief item of medical interest in the report concerns the new regulations for clinical teaching. The council has been negotiating with the Board of Education with a view to obtaining grants for medical instruction. In order to take advantage of this new source of income it was necessary to constitute a University clinical board to take over the work previously carried on by the Birmingham Clinical Board and to appoint as members of the staff of the University the whole of the teachers engaged in clinical teaching. In addition the Board of Education required that to ensure permanence of clinical teaching the hospitals should undertake to continue to provide facilities, subject to six years' notice being given at any time they considered it desirable to discontinue the admission of University students to the wards of the hospitals. The committees of the General and Dental Hospitals have accordingly passed resolutions in this direction. In the case of the Queen's Hospital a special Act of Parliament imposes upon the hospital the duty of providing clinical instruction.

Association of Public Vaccinators of England and Wales.

The annual meeting of this association was held in the Midland Hotel on March 1st. Mr. A. H. Martin, of Evesham, was elected president, and Dr. Arthur Drury, of Halifax, gave an interesting address. In the evening the annual dinner was held and was largely attended, not only by the members but by several local members of the profession who had been invited as guests. There was an interesting toast list, "The Association" being proposed by the President and responded to by Dr. A. E. Cope, who eloquently pleaded for a greater recognition of Jenner's services as the founder of preventive medicine. Dr. Drury proposed "The Guests of the Association," and referred to the great loss the association had sustained by the death of Dr. F. T. Bond, of Gloucester. Professor Robert Saundby, the President of the British Medical Association, responded. He described his own attitude towards the Insurance Act, originally stated in his presidential address in July, and from which he had not wavered. He regretted that a majority of the Council had differed from him, and failed to realise the strong feeling shown by the mass of the medical profession in the country. Dr. G. A. Wilkes proposed "The Public Health and Poor-law," and Dr. J. Robertson, medical officer of health of Birmingham, responded. Interest was given to the meeting by the exhibition of two letters of Jenner and an original diploma of membership of the Jennerian Society, which were in the possession of Dr. Drury.

March 5th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Formal Opening of the New St. Paul's Eye Hospital.

ON Feb. 27th the new St. Paul's Eye Hospital was formally opened by the Earl of Derby in the presence of a large and influential gathering. Lord Derby, in declaring the hospital open, said there was a special feature of the hospital which he wished to commend—namely, the bringing of the mother and the newly born infant straight into the hospital, in order that the infant could be treated before the disease (ophthalmia neonatorum) had got a hold upon it. By that means they would be able to check the disease, which nine times out of ten, if not treated, would land the child not into a hospital of the kind, but into a blind asylum or some similar institution. Mr. Sydney Stephenson (London), in moving a vote of thanks to Lord Derby for presiding, made feeling reference to the late Mr. George Edward Walker, remarking that the opening of that hospital was the crowning point of a career devoted to humanity. Its founder was one who believed that the greatest care should be given to children, recognising, as he did, that the hope of the future was the child. In that hospital they had accomplished a scheme for the treatment of ophthalmia neonatorum. In this, as in other respects, Liverpool had led the way, and it had not only attracted interest in this country but on the Continent and

in America. They had a scheme there for the prevention of blindness which would surpass the wit of man to exceed. The truth was that a philanthropist's dream had been converted into a sound, salutary, and substantial success. Dr. Arthur N. Walker, in seconding, mentioned that his father had always cherished the ambition of having established in Liverpool a hospital such as they now possessed. One of the greatest benefits of that building was the accommodation provided for children. They could take in cases at the beginning and stop disease. It was a happy omen, he thought, for the hospital that in the past year they had treated more cases than ever before of ophthalmia in infants, and for the first time not one case in Liverpool had resulted in blindness. Lord Derby was presented with a gold key the head of which was formed after the shape of the Maltese cross, and which was supported on a prettily chased acanthus leaf cluster. In the centre panel were the arms of the Earl of Derby. Amongst the ladies present, probably the most interested spectator was Mrs. George E. Walker, the widow of the late founder of the hospital.

Sir Benjamin Johnson on the Medical Aspects of the Insurance Act.

At the annual meeting of the Everton Liberal Association, held last week at the club premises, an interesting speech was delivered by Sir Benjamin Johnson, the leader of the Liberal party in Liverpool. Referring to the Insurance Act, Sir Benjamin Johnson said that having once agreed to the doctrine of compulsory insurance—which all parties had done apparently without a qualm—it was childish to quibble as to the consequences. A great experimental measure such as the Insurance Act was bound to have defects and weaknesses which experience alone could remedy. Mr. Lloyd George had told them that the Act would be worked independently of the doctors. He, for one, felt that an Insurance Act unattended by medical benefits would be shorn of its real value as a great measure for the promotion of national health. He did not think that Mr. Lloyd George was altogether to blame for the trouble connected with the doctor's remuneration. Contract practice had been almost universal in the medical profession for generations, but there was no doubt that the bulk of the profession had been preparing, prior to the introduction of the Act, to put it on a better basis, and the advent of the Insurance Act had precipitated the revolt. It was of enormous importance in the fight against sickness and disease to have the willing and thorough coöperation of the doctors, and the 4*s.* 6*d.* capitation fee was, in his judgment, inadequate to secure that end. The Government had declared that they were willing, on proof being shown that the amount fixed by the Act was inadequate, to reconsider the terms; and he trusted that as a result of negotiations between the British Medical Association and the Insurance Commissioners a satisfactory compromise might be reached. Failing such a settlement he believed the Act would be a comparative failure, instead of a regenerative force making for the building up of a healthier and stronger nation.

Banquet to Sir William Lever.

Sir William Lever, the chairman of the Liverpool School of Tropical Medicine, and Lady Lever were entertained to dinner at the Adelphi Hotel on Feb. 29th by the staff of the school on their return from a visit to South Africa.

March 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Hospital for Women and Children and the Hospice.

AT the annual meeting of the Edinburgh Hospital and Dispensary for Women and Children and the Hospice held in Edinburgh on Feb. 29th, Lady Kinross presiding, the report of the executive committee made especial reference to the opening of the new wing of the hospital by Her Majesty the Queen in July, 1911. The amalgamation of the two institutions was now completed, the Hospice being entirely reserved for maternity cases. Since the amalgamation there had, however, been a falling off in subscriptions for the two institutions, and in consequence one of the wards in the hospital, for patients paying at the rate of 5*s.* weekly, had had to be closed. In the report of the treasurer this falling off was stated in several cases to have been the result of the increased taxation in the country. The medical report referred to the necessity for a children's ward in the hospital as well as for the reopening of the second 5*s.* ward, and drew attention to the work done at the infant consultation and milk depôt in the High-street. Since the opening of the new wing at the hospital there had been a gratifying increase of work, especially on the surgical side. The adoption of the reports was moved by Mr. G. A. Berry, President of the Royal College of Surgeons of Edinburgh. A tribute was paid to the memory of the late Dr. Sophia Jex-Blake, founder of the hospital.

Presentation to Dr. John Fraser.

On Feb. 27th a gathering of ladies and gentlemen took place in the hall of the Royal College of Physicians of Edinburgh, when a presentation was made to Dr. John Fraser, who lately retired from the position of H.M. Commissioner in Lunacy for Scotland. The presentation took the form of a three-quarter length portrait of Dr. Fraser by Mr. Fiddes Watt, A.R.S.A. The chair was occupied by the Master of Polwarth, chairman of the Board of Lunacy, and among those present were Dr. Byrom Bramwell, President of the Royal College of Physicians; Sir Thomas and Lady Clouston; Mr. Addison-Smith; Dr. Urquhart; Dr. Campbell; Dr. Turnbull, Dr. John Macpherson, Dr. Hamilton Marr, and Mr. John Cowan, W.S., H.M. Commissioners for Scotland; Dr. Charles Macpherson, Deputy Commissioner; Dr. G. M. Robertson, superintendent, Royal Edinburgh Asylum; Mr. T. W. L. Spence; Dr. Carlyle Johnstone, Dr. James Ritchie, and Dr. Carmichael. The chairman spoke of his own good fortune in having had during the whole of his tenure of the chairmanship of the Board of Lunacy Dr. Fraser as his colleague. He referred to the advances that had taken place in lunacy work during that time, and gave an appreciative tribute to the kindly disposition of Dr. Fraser, which, he said, must have had a great influence on all concerned with the care of the insane in Scotland. Sir Thomas Clouston, in making the presentation, referred to Dr. Fraser's career as a student and later as a graduate, and spoke of the presentation which was being made by some 200 of Dr. Fraser's friends as representing friendship and comradeship in every part of the world. Dr. Fraser, in reply, expressed his pride and gratitude at the honour done him, and his deep regret that his connexion with lunacy administration, and with Scottish administration generally, had now drawn to a close.

March 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal National Hospital for Consumption.

THE report presented at the annual meeting of the Royal National Hospital for Consumption, which was held last week in the hall of the Royal College of Physicians, stated that 436 cases had been treated during the year. Of these, 339 were discharged and 90 remained in hospital on Dec. 31st last; seven patients died. The board reiterated its intention of keeping the benefits of the hospital as a curative institution for incipient and early cases of the disease. The hospital had received £3000 of Lord Iveagh's gift to the King, and the money would be used for the provision of recreation rooms. The chairman of the meeting, Major Wellesley, said that the board knew nothing of the reported suggestion to erect a hospital for advanced cases in the hospital grounds, which, he said, were quite unsuitable for such a purpose. During the year a system of graduated labour on the prescription of the medical officer had been introduced, with the purpose of preparing the patient on leaving the hospital to resume his ordinary work. Tuberculin was administered more extensively than formerly. A dental surgeon has been appointed to visit the hospital periodically. The medical report classified the results of treatment as follows: Very much improved, 4·3 per cent.; much improved, 23·1 per cent.; improved, 21·1 per cent.; stationary, 17·6 per cent.; worse, 9·4 per cent.; died, 1·6 per cent.; remaining in hospital, 20·6 per cent.

Dinner of the Dublin University Biological Association.

The annual dinner of the Dublin University Biological Association was held on March 2nd at the Gresham Hotel, Mr. Arthur Ball, the President, being in the chair. It was well attended by present and past members. Among the guests were Dr. Traill, Provost of Trinity College, Professor Culverwell, Professor T. H. Wilson, and Mr. W. Kennedy.

Convalescent Home, Stillorgan.

At the annual meeting of the Stillorgan Convalescent Home, held on March 4th, it was stated that the home last year received 1348 patients. An annexe containing 20 additional beds had been added. The home, which is situated a few miles out of Dublin, receives patients from the various Dublin hospitals.

The Belfast Maternity Hospital.

At the annual meeting on Feb. 27th it was reported that during the year 567 patients were treated and 382 children born. There were 8 maternal and 25 children's deaths. There were also 556 extern cases, with 1 death, so that in all 1123 patients (extern and intern) were treated, with 9 deaths, representing a death-rate of 0·8 per cent. There were also 360 extern gynæcological cases. The one unsatisfactory feature in the report was the slight falling-off in subscriptions which, though only £10, was the first decrease for many years.

Health of Belfast: High Death-rate.

In the report presented to the city corporation of Belfast on March 1st for the period between Jan. 14th and Feb. 17th the total death-rate was actually 30·8, being 12·9 higher than in the preceding month, and 14·1 higher than in 1911. This extraordinarily high mortality was due to deaths from chest affections, which gave a rate of 14·9, or about 9·4 in excess of the normal. Further, the zymotic death-rate, 2·5, was abnormally high, the excess being due to whooping-cough, the deaths from which were 70 as compared with 19 in the previous month, and 3 in the corresponding month of 1911. Pneumonia was responsible for 237 deaths, and chest affections for 226. The following table shows the mortality from pneumonia, diarrhœa, whooping-cough, and measles in Belfast during the past five years:—

Year.	Pneumonia.	Diarrhœa.	Whooping Cough.	Measles.
1907	696	212	64	201
1908	753	260	137	186
1909	705	244	213	10
1910	622	241	259	504
1911	468	290	67	2
	3244	1247	740	903

The National Insurance Act.

In various parts of Ireland considerable objection is being made to insurance lectures, in some places in consequence of objection to the Act, in others to the lecturers' previous political records. The Londonderry No. 1 rural council, on March 2nd, ordered simply to be marked as "read" a letter from the National Insurance Commissioners asking for the use of the council's offices for an explanation lecture.

Extraordinary Demand for Income-tax.

At a meeting of the Coleraine board of guardians on March 4th, a communication was received from the surveyor of taxes, Belfast, demanding from them income-tax on their balance in bank. The guardians desired their clerk to inform the surveyor that they declined to pay, inasmuch as they had no money except what was collected from the rates.

Rain-fall in February.

During the month of February rain fell on 18 days to the amount of 3·24 inches, which, added to the January fall, brings this year's total rain-fall up to 6·56 inches in the north of Ireland.

March 5th.

UNIVERSITY OF BRISTOL.—At a meeting of the Council held on March 1st Mr. Ernest W. Hey Groves, F.R.C.S., was appointed Lecturer in Surgery to dental students.—The thanks of the Council were given to the Bristol Royal Hospital for Sick Children and Women and the Victoria University of Manchester for gifts of valuable specimens to the pathological museum.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Reform of Medical Studies.

A TENDENCY towards reform in medical studies has prevailed for many months at the Faculty of Medicine of Paris, and, indeed, throughout France. It is directed towards both the medical curriculum and the different kinds of examination for appointments. The last part of this subject has not as yet been definitely settled, for the changes introduced in 1909 have satisfied no one, and the Minister of Public Instruction wishes to take advantage of the coming into force of the new decree concerning medical studies to effect a serious reform in the matter of appointments. To this end he has called on the Association of Members of the Teaching Bodies of the Faculties of Medicine to furnish a plan. Professors Roger, Pierre Delbet, and Weiss have been called on to report on the methods of appointment, while the legal status of the *agrégés* is being studied by Dr. Carnot and Dr. Jeanbrau, who advocate life appointments in preference to a nine years' term. The three professors have each been allotted for consideration one of the three sections—viz., medicine, surgery, and science properly so called—between which the examination for appointments is divided. Professor Roger, for medicine, advocates a common entrance examination lasting three-quarters of an hour, the submission of qualifications, and the examination in six special subjects—viz., medicine, dermatology, neurology, hygiene and legal medicine, pathological anatomy, and experimental and comparative pathology. The specialties in surgery will be gynæcology, surgery of infants, and genito-urinary diseases, but Professor Selbet thinks that these special subjects should be of a practical rather than a scientific nature. He also ascribes great importance to practical tests, which he would have strongly developed. Differing from his colleagues and even the general opinion, he would not hesitate also to exact from the candidates tests of memory. In his opinion a clinical teacher ought to be able to improvise a lesson on any subject that may present itself. Professor Weiss would divide the section of sciences into anatomy and histology, natural history, physiology, physics and chemistry, and pharmacology.

On the other hand, the Superior Commission met on Feb. 23rd, under the presidency of M. Liard, vice rector of the Academy of Paris, to examine the report of Professor Courmont, of Lyons, on the reform of medical examinations, and passed some important resolutions. It decided to include on the board of clinical examiners at the final examination physicians, surgeons, and accoucheurs of the hospitals agreed on by the Faculty as being in charge of the clinical course. The Commission voted, also, that after a certain number of failures at the same examination the student should be precluded from continuing his studies. M. Léon Labbé insisted on the importance of a knowledge of practical anatomy and surgery, now that, thanks to antiseptic and aseptic principles, all practitioners may be called on to perform certain operations. He also supported an amendment, according to which surgical anatomy should become a special subject of examination at the finals. The Superior Commission, after a lengthy discussion, decided on the introduction into one of the yearly examinations of an examination in stomatology. It also sanctioned the introduction of dentistry at the Faculty of Medicine.

National Conference of the "Gouttes de Lait."

The meeting of the medical founders and directors of the "Gouttes de Lait" will take place at Fécamp on May 26th, 27th, and 28th, on the initiative of Dr. Variot, Dr. Brunon, and Dr. Dufour, the organisers of the First International Congress of the Gouttes de Lait. At this conference, to which many promises of attendance have already been secured, the results so far obtained will be reported, and ways and means of rendering still more efficacious the struggle against excessive infant mortality among those brought up by hand will be sought. Infant feeding will be the main subject for consideration at this conference.

Appendicitis and Dysentery.

At the Société de Chirurgie recently M. Ombre made

a communication for M. Le Roy des Barres, on the Relations between Amœbic Dysentery and Appendicitis. The author thinks that when there is an amœbic infection of the appendix there is at the same time amœbic infection of the colon, but the infection of the appendix may be anterior, simultaneous, or posterior to that of the colon. Such cases of appendicitis, according to M. Le Roy des Barres, are purely amœbic, and he relies for proof on amœbic lesions of the appendix, but he by no means proves that secondary nfections play no part; indeed, in a large number of cases they do. The diagnosis between what appertains to the dysenteric typhlitis and what to the appendicitis is very difficult. In the case of light dysentery, with the appendicular signs but little marked, surgical intervention is contra-indicated, and medical treatment should be followed. On the other hand, whenever the crisis is severe or even clearly marked, operation should always be done. Under such circumstances appendicectomy is called for with the formation of a fistula of the cæcum in one or two operations.

The Treatment of Boils.

M. Gallois considers that furunculosis is a purely local disease resulting from repeated inoculations. The treatment, therefore, should be exclusively a matter of dressings. Discarding the use of water and of poultices, the author extols a method which consists of aborting the furuncles, if possible, by the local use of a drop of iodoacetone and applying locally a gauze compress well impregnated with glycerole of starch, to which boric acid or mercury oxycyanide has been added. Over this is put a layer of absorbent cotton without any impermeable covering, the whole being kept in place by a bandage. This dressing should be renewed every day or even twice daily. To cause desiccation it should be dusted with talc powder, to which a little paraffin has been added.

March 4th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The German Committee for the Forthcoming International Medical Congress.

A MEETING of representatives of medical societies, of official medical authorities, and of the medical press was held on Feb. 16th, in Langenbeck House, Berlin, for the purpose of electing a general committee for the International Medical Congress in London. Professor Waldeyer, who was in the chair, stated that 84 universities, medical post-graduate schools, medical societies, and journals were represented, and that many answers had been received from other medical bodies agreeing to send representatives to London. The committee was then elected, the officers being as follows:—President: Professor Waldeyer. Vice-Presidents: Professor Kirchner and Professor Kraus, of Berlin; Professor Döderlein, of Munich; and Professor Marchand, of Leipsic. General secretary: Professor Posner. Assistant secretary: Professor von Hansemann. Treasurer: Dr. Ernst Stangen. The committee will also include Professor Gudden of Munich, Professor Goldscheider and General-Surgeon Dr. Kern, of Berlin, Professor Schwalbe, editor of the *Deutsche Medizinische Wochenschrift*, and Professor Sonnenburg. The meeting agreed that the committee shall be a permanent one, and deal with the organisation of future international congresses in concert with the International Permanent Committee. Professor Sommer, of Giessen, moved that a whole day of the congress should be devoted to the discussion of the question of heredity in connexion with the several branches of medicine. The proposal was favourably received, and was referred to the Executive Committee for further consideration.

Operative Treatment of Tuberculosis of the Bladder.

At a recent meeting of the Medical Society Professor Casper read a paper on a method of relieving urinary troubles in tuberculosis of the bladder. He said that as the majority of cases of tuberculosis of the bladder were caused by tuberculosis of the kidneys; some of them might terminate in recovery after removal of the diseased kidney. In certain cases, however, where the kidney was either inoperable or where the tuberculosis of the bladder was in a too advanced state the tuberculous lesion of the bladder might continue or even increase. Cases attended with intolerable tenesmus and with contraction of the bladder to a capacity of only 20 or 30 cubic centimetres and in which all other therapeutical measures had proved useless were suitable for his operation. He had operated on two cases. One patient was a woman on whom nephrectomy had been performed seven years ago for tuberculosis, the result being that, notwithstanding a slight tuberculosis of the bladder, no pains had been felt for six years, but she subsequently suffered from severe pains and very frequent micturition. The urine was turbid and contained tubercle bacilli. The left kidney proved to be much enlarged and the capacity of the bladder was 30 grammes only. Cystotomy proved useless, the pains not being at all relieved by it. Professor Casper therefore performed nephrostomy by uniting the pelvis of the kidney to the skin, ureterostomy being impossible because of the abnormal situation of the hilus. The pains were relieved, but the secretion of urine through the fistula was very small, and eventually stopped altogether, notwithstanding the employment of irrigation through a drainage-tube. The vesical troubles disappeared, but the patient died on the seventh day after the operation. The second patient was a man 36 years of age on whom nephrectomy had been performed six years ago for tuberculosis of the left kidney. Previously to the operation severe pains had been felt in the bladder, but they were considerably relieved by the operation, so that the patient could work as a locksmith, but six years after the operation his state again became very bad, tenesmus and vesical pains ensuing which resisted all therapeutical measures. The urine was passed every half hour; it was purulent, but did not show tubercle bacilli. The capacity of the bladder had diminished to 80 grammes, and the patient had become greatly emaciated. Catheterism of the right ureter yielded clear urine with a small quantity of leucocytes. The sediment inoculated into animals rendered them tuberculous. Professor Casper performed ureterostomy, uniting the upper end of the divided portion to the skin and thus forming an artificial outlet in order to exclude the bladder. There was an abundant discharge of urine through a catheter kept permanently in the fistula, the result being that the pains completely disappeared the day after the operation. The state of the patient was very good; by irrigation through the catheter the urine soon became clear and had continued to be so. The patient wore a receptacle for holding the urine. His weight increased six kilogrammes. Professor Casper said that this result proved that severe vesical pains might be relieved by excluding the bladder. Ureterostomy was, in his opinion, preferable to nephrostomy, for the latter, although a simpler operation, had eventually an injurious effect on the function of a tuberculous kidney, as shown in the first case above mentioned. Ureterostomy was more difficult from a manipulative point of view, but it did not injure the kidney. It was advisable to implant the ureter into the skin either in the lumbar or the supra-inguinal region. During the first few days a catheter must be left permanently in the ureter. The operation was indicated not only when the remaining kidney was tuberculous but also when it proved healthy, because by cutting off the communication between the bladder and the kidney the danger of an infection from the bladder was diminished. Pyelitis, which might be a sequel to ureterostomy, was less dangerous than tuberculous infection. In the discussion Professor Israel recommended the making of a suprapubic fistula of the bladder instead of a ureteral fistula, because of the danger of pyelitis. Professor Landau said that the method of Professor Casper seemed to be preferable to establishing a fistula of the bladder because of the impossibility of applying an apparatus to receive the urine in fistula of the bladder. Professor Casper replied that, according to his experience, after the formation of a vesical fistula the pain was not only not relieved, but even became more intense.

The Action of Salvarsan in Anthrax.

Professor Bettmann and Dr. Laubenheimer, of Heidelberg, have contributed to the *Deutsche Medizinische Wochenschrift* an article on the Action of Salvarsan in Anthrax. Professor Bettmann stated that in two cases of anthrax attended in his clinic the symptoms disappeared rapidly after the injection of 0·3 gramme of salvarsan into a vein. Dr. Laubenheimer has accordingly made experiments on animals, especially on guinea-pigs and mice, which are very susceptible to the infection of anthrax, and in which the course of the disease

is not identical with that of human anthrax, for in the latter case spontaneous recovery may occur, but in the lower animals a highly virulent infection is always fatal. The result of the experiments was that animals treated by salvarsan not later than 20 minutes after inoculation with anthrax all survived, except one, which died 22 days after the inoculation. All the other animals either remained alive or died from some other cause than anthrax; a few of them died from poisoning by salvarsan. Sometimes the animals were saved by salvarsan when injected with it even six hours after the inoculation with anthrax, and the germs disappeared. When the salvarsan treatment was longer delayed a fatal issue could not be avoided, but the animals died later than those which had not received an injection of salvarsan. Salvarsan acted as a disinfectant by directly destroying the anthrax bacilli and their spores. Sometimes only the development of the germs was hindered, allowing them to increase and cause death after the salvarsan had been eliminated from the organism. In the test-tube salvarsan hindered the development of the germs to a remarkable degree. Animals which had been cured of anthrax by an injection of salvarsan were not rendered immune against a later infection. The experiments showed that salvarsan by destroying the anthrax bacilli might be a valuable remedy against the disease.

March 4th.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Medical Legislation.

General Smuts is due to reintroduce the Public Health Bill. Whether it will appear in the form it did last year, when it was laughed out of the House, remains to be seen. As it appeared then its only object was to vest in the Minister of the Interior the powers, duties, and functions of the respective medical officers of health of the four Provinces. General Smuts has announced that he is not prepared to introduce a Bill to consolidate the law relating to the practice of medicine this session, or even to allow a licence granted by the Medical Council of one province to be operative in another. He has, however, at least been induced to promise that the draft Bill will be submitted to the medical profession before it is introduced into the House next year.

Treatment of Lunatics.

The Prisons Bill which was passed last year renders it illegal for any lunatic to be received into a prison hospital if there is any public asylum or hospital in the district. Now this provision is, of course, a most proper one and received the warm support of the medical profession, particularly as an assurance was given by the Government that immediate provision would be made for dealing with lunatics in these districts at the asylums or elsewhere. No such provision has, however, been made, and magistrates appear to be at their wits' ends to know what to do with cases of lunacy pending accommodation being found in the overcrowded asylums. It has become a practice to hire on behalf of the Government empty houses and to place patients therein, as often as not in the charge of policemen. These patients are consequently far worse off than they used to be, for now they are deprived of the conveniences to be had in the gaol hospitals. It is true that the stigma attached to incarceration in the gaol is removed, but as the bulk of the patients are natives the stigma is possibly more imaginary than real. At any rate, the present state of affairs is too horrible to be allowed to remain, and is a disgrace to the administration. Although full publicity has been given to the facts in the lay press it would seem that the increase in the asylum accommodation proposed during the current year will be insufficient to relieve the congestion to any great extent.

Closure of the Sydenham Asylum.

The Sydenham Leper Asylum, situated a few miles outside Bloemfontein, is shortly to be closed, and the inmates and a portion of the staff are to be transferred to the asylum at Pretoria. The unfortunate inmates, the majority of whom are natives, number about 160, and they are drawn almost exclusively from different parts of the Orange Free State. There is likely to be some trouble in carrying out the transfer, as it is almost certain that objections will be raised in Parliament. It will involve a good deal of hardship on the inmates, for hitherto it has been easily possible under the existing arrangements for friends and relatives occasionally to visit them, but in future this will be quite out of the question. Mr. W. C. C. Pakes, the former Government bacteriologist of the Transvaal under the Crown Colony Administration, and for some years past the superintendent of the Sydenham Asylum, is to be retrenched.

Rand Water Shortage.

For some weeks past the position in Johannesburg has been very grave owing to the shortage of water supplied by the Rand Water Board. The fact is that the requirements of the town and mines have increased out of all proportion to the increase in the supply furnished by the Board. On several occasions the municipal reservoirs have been nearly empty, and it would seem to be imperative that steps should be taken to procure water from other sources of supply.

Proposal to Establish a Municipal Dairy at Bloemfontein.

Amongst a number of important questions at present engaging the attention of the Bloemfontein town council is that of the establishment of a municipal dairy. Dr. D. M. Tomory, the municipal medical officer of health, has asked his council to vote £3000 for this purpose, with the object of showing what can be done with a pure milk-supply. The project is meeting with some opposition from dairymen, but it is likely to go through. It is to be hoped that it will, as many of the existing dairies are far from suitable, and the effect will be that these will have to be improved or they will be ousted by the municipal undertaking. This project, if carried out, will be the first of the kind undertaken by a municipality in South Africa. There has been some difficulty in selecting a suitable site, and in order that the milk may be conveniently brought to the cooling chambers of the municipal premises it has been suggested that the dairy should be erected on the commonage to the east of the town.

Plague at Durban.

Three cases of bubonic plague were discovered in Durban during the past month—all terminating fatally. Two of the cases appear to have been employed in the dock area, whilst the third worked in a store outside the town. This is the first outbreak that has occurred in South Africa since 1907. Two of the cases were both working in sheds in which rats had evidently been dying from plague for some months past, whilst the third was connected with an infected store in the town. At first hopes were officially expressed that the infection was confined to the dock area, but an examination of stores in the town quickly revealed the fact that rats were dying of plague in a number of widely separated areas at a considerable distance from the docks. Dr. F. A. Arnold, the acting medical officer of health for the Union, has been in Durban to consult with the Mayor and Dr. P. Murison, the municipal medical officer of health, and as a result of his visit an agreement has been drawn up defining the respective spheres of operations of the Government and municipality. A special plague committee has been appointed, consisting of an equal number of nominees of the Government and the Durban corporation, and this committee has been given full power to deal with all matters relating to the outbreak within the borough and harbour area. Special plague regulations have been promulgated. Fortunately Durban has a well-organised health department which is working under the direction of the plague committee, and energetic measures are being taken to deal with infected premises and to destroy rodents throughout the town. The plague committee has been issuing encouraging bulletins from day to day, but inasmuch as the outbreak has occurred at a time of the year most favourable to the spread of rat plague in this country it would seem hardly probable that the measures which have been instituted will do more than control the outbreak until, at any rate, it has run its course amongst rodents in the area, the same as it apparently has always done in the past whenever it has been permitted to get a hold on any centre in South Africa. The infection is believed to have been introduced from Mauritius, but the vessel which brought the infection is not known with any certainty. Two comments on the situation may fairly be made. Had the Natal health department not been prematurely broken up there appears to be some reason to think that under the *régime* inaugurated by Mr. Ernest Hill, the late health officer of Natal, a stricter

watch would have been kept at the port for disease amongst rats, and that the mortality might have been discovered in time to have confined the outbreak to the dock area; and, secondly, that the special plague committee would not have been necessary, for the organisation to have dealt with the outbreak would have existed in the province, and money would doubtless have been saved the taxpayer. Apart from the operations now being undertaken in Durban, a number of municipalities have awakened to a sense of their responsibilities, and are spending money on destroying rats and rectifying insanitary conditions. Thus, Johannesburg is spending £30,000 on putting the insanitary location hereafter mentioned into a better state.

Small-pox in Johannesburg.

An outbreak of small-pox has broken out in the location of Johannesburg just referred to, which is known as the Malay location. This has caused considerable anxiety to the community, and but for the prompt action of the municipal medical officer of health, Dr. C. Porter, it might easily have assumed serious proportions. The outbreak had been in progress some days before it was discovered, and consequently a considerable number of the inhabitants of the location were contacts, including a number of unvaccinated persons. At the time of writing it would seem to have been successfully confined to the location and to have been practically stamped out therein.

Anthrax on the East Rand.

An extensive outbreak of anthrax amongst cattle has been discovered on the East Rand, which has evidently been in progress for some time. This disease is always specially dangerous in South Africa, as most natives will feed readily on the half-cooked flesh of animals dead from disease. A large number of cattle are officially reported to have died from the disease already, and one adult native. It is probable, however, that there have been other deaths which have not been recorded. The Agricultural Department has taken up the matter and has imposed stringent quarantine over the area. It was, however, uncommonly slow in acting in the first instance.

Feb. 1st.

Obituary.

SIR FRANCIS RICHARD CRUISE, M.D. DUB., F.R.C.P. IREL., M.R.C.S. ENG., D.L.,

PHYSICIAN TO HIS MAJESTY THE KING IN IRELAND; CONSULTING PHYSICIAN TO THE MATER MISERICORDIÆ HOSPITAL; EX-PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND; KNIGHT OF ST. GREGORY.

Sir Francis Cruise died at his residence, 93, Merrion-square, Dublin, on Feb. 26th, in his seventy-eighth year. His death removes one of the most prominent of Dublin physicians, and the Senior Fellow of the Royal College of Physicians, of which he was President from 1884 to 1886. He was born in Dublin on Dec. 3rd, 1834; his father, who was a solicitor in good practice, descended from an ancient Meath family, died when he was only a few weeks old. The son's education did not suffer, however, thanks to the fact that his mother was a wise and cultured woman, who strove successfully to lay the foundations of his character deep in religion and scholarship. He received his early education from the Jesuit Fathers in Belvedere College and Tullabeg, and entered Trinity College, Dublin, in 1852, graduating as B.A. in 1857 and as M.B. in 1858. In the School of Physic in Trinity College he came under the influence of such men as Banks, Apjohn, and Robert William Smith. At the House of Industry Hospitals, where he took his clinical work, he had as teachers Adams, Smith, Banks, Lyons, and Corrigan. He attended lectures also at the Carmichael School, where he did much scientific work in association with Robert McDonnell. His health gave way under the strain of excessive work, but was restored after a trip to America.

In 1861 the Mater Misericordiæ Hospital was opened, with Cruise as junior physician. The rest of his professional life was associated with this institution, in the development of which he took a very important part. At the jubilee celebrations of the hospital last September Cruise was naturally a prominent figure. His early years in medical practice in Dublin were lean enough, his earnings from private patients in his first three years being £7, £11, and £30. At this time he was much occupied with teaching; subsequently, however, he enjoyed for more than a generation one of the best practices in Dublin. Although at first interested in surgery, in his later years Cruise devoted himself entirely to medicine. In 1865 he introduced an "endoscope" for the internal examination of the body cavities, which proved particularly useful for the exploration of the bladder. Considering the only illuminants available at the time, it was a remarkably ingenious application of reflected light. In his own hands and in those of others who accustomed themselves to its use it was of considerable service. It is worth remembering that by the invention of this instrument, the precursor of the modern cystoscope, Cruise was a pioneer in bladder surgery. In the eighties his attention was attracted to hypnotism, and in 1890 he visited Nancy and Paris, observing the work of Liébault, Bernheim, Luys, Voisin, and others. He published his notes of this journey on his return to Dublin in the *Dublin Journal of Medical Science*, May, 1891. So recently as 1907 he wrote an introductory chapter to Dr. Lloyd Tuckey's book on "Treatment by Hypnotism and Suggestion." On other subjects of general medicine he was a prolific writer, and frequently contributed to the medical journals. In his work at the Mater Misericordiæ Hospital he was a careful clinician and a lucid and inspiring teacher. In professional life in Dublin he was held in the highest respect, and he interested himself in all public matters affecting the profession. He had, however, many activities outside his profession. As a citizen he was interested in many charities and philanthropic works. He was also a cultured musician.

In literary pursuits his interest extended widely outside of medicine. His boyhood's devotion to "The Imitation of Christ" matured in adult life, and he visited many foreign libraries and consulted innumerable manuscripts, with the purpose of establishing beyond doubt (which he eventually did) that Thomas à Kempis was veritably the author of this famous book. It is interesting to know that the citizens of Kempen, in Germany, have named one of its streets in his honour, in recognition of his vindication of their famous townsman. Cruise belonged to a type of physician more rare now than formerly. While thoroughly conversant with the best in medicine, he was also a cultured scholar in other fields. In character he was a man of deep religious convictions, of humble mind, and of great personal charm. He married in 1859 Miss Mary Power, and in 1909 they celebrated their golden wedding. By her death a year later an ideally happy union was severed. He leaves a large family, of whom one son is a medical man.

In 1896 Cruise received the honour of knighthood. Ten years later he declined a baronetcy. In 1901 King Edward appointed him his physician-in-ordinary in Ireland. In 1905 Pope Pius X. conferred on him a knighthood of St. Gregory.

RICHARD DILL, M.D. EDIN., L.R.C.S. EDIN.

BY the death of Dr. Richard Dill, which occurred at Birchwood, Burgess Hill, Sussex, on Feb. 24th, a link has been broken in the chain of Brighton's past history. Born in Ireland in 1822, he was the youngest son of the Rev. Richard Dill, of Newtown Limavady, by his marriage with Jane, daughter of Robert Gordon, Carnstrone House, Antrim, who, with her sister and co-heiress, were the sole remaining representatives of the Jacobite house of Gordon of Glenbucket.

Richard Dill took the L.R.C.S. diploma at Edinburgh in 1845, and proceeded to the M.D. degree in the same year. He was a favourite pupil of Sir James Young Simpson, the discoverer of chloroform as an anæsthetic, but declining the great physician's suggestion to start practice in Edinburgh under his auspices he went to China, where he spent several eventful years.

A cousin who held a Government appointment at Hong-Kong decided this visit to China, and Dill travelled in the interior and on the coast, and made a valuable collection of ferns, including some unknown varieties which he handed over to Sir Joseph Hooker at Kew on his return. He also accompanied for about 1000 miles Robert Fortune, the famous explorer and botanist, who was then introducing the tea plant from China into the North-West Provinces of India, and thus laying the foundation of the Indian tea industry.

In these travels Dr. Dill had many adventures, and seized every opportunity of practising his profession under the new and exhilarating conditions. On one occasion when he arrived at a village he found that his medical fame had preceded him, and that a number of people suffering in various ways were waiting for him. Among these was a woman with a central cataract in each eye, whose pupils he dilated with belladonna, so that she was able to see her son for the first time for years, a result which she and her friends proclaimed as a veritable miracle.

He came back to England in 1849 and settled at Brighton, joining his uncle, the late Mr. John Dill, in practice. Mr. John Dill was a very interesting person, who, after beginning life as an officer in the navy of the East India Company, had resigned his commission and studied medicine, re-joining the service as surgeon. Later he began to practise at Brighton in partnership with a Mr. Drummond in Regency-square. With this firm Richard Dill continued in partnership until death left him the only survivor, and for a long generation he enjoyed a very high professional position in Brighton. He did not retire until the end of the nineteenth century, having attained a high reputation as a physician, and having made many fast friends among the leaders of the profession, not only in the British Islands, but upon the continent. He owed his success in practice firstly to a sound judgment, a receptive brain (which up to the last kept him abreast of all the most recent developments of scientific research), and an unusual knowledge of therapeutics; but secondly to the intimate and individual sympathy with his patients as men and women which his temperament enabled him to offer. His personal ideals of the conduct of life were very high, and he carried them uniformly into the practice of his profession; and it is not too much to say that every patient of his was left with an enhanced estimate of our profession, as well as with confidence that his own needs were being anxiously met. He was a man of the deepest religious conviction, who was ready to credit others with the single-mindedness and generosity which marked his own actions. For upwards of 50 years he carried on in Brighton a very active professional life, being also keenly interested in all matters concerning the sanitary advancement of the town. He saw Brighton grow from its Georgian position to what it is to-day.

Retiring from practice some ten years ago, he took up his residence at Burgess Hill, and there celebrated his golden wedding. His wife, a daughter of Sir Charles Wale, K.C.B., survives him, as do two out of his four sons, the elder being Dr. J. F. Gordon Dill, the senior physician to the Royal Sussex County Hospital. Dr. Dill died peacefully in his sleep. His health had been failing for some time, but the actual cause of death was a sharp attack of influenza.

HENRY FITZGIBBON, M.D. DUB., F.R.C.S. IREL.,

CONSULTING SURGEON TO THE ROYAL CITY OF DUBLIN HOSPITAL AND TO MERCER'S HOSPITAL; EX-PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

Mr. Henry Fitzgibbon, one of the best-known Dublin surgeons and a past President of the Royal College of Surgeons in Ireland, died at his residence, 24, Fitzwilliam-place, Dublin, on Feb. 23rd, in his seventy-first year. He was the younger son of the late Gerald Fitzgibbon, Q.C., a Master in Chancery, his elder brother being Lord Justice Fitzgibbon, one of the most distinguished jurists of our time. Mr. Fitzgibbon had been in failing health for some years past and had resigned most of his appointments within the last few months.

Henry Fitzgibbon received his medical education in Trinity College, Dublin, where he graduated as M.B. in 1866. He was for some time in the Poor-law Service, being dispensary doctor, first at Clondalkin, and afterwards at Howth, both in County Dublin. On his election as surgeon to the City of Dublin Hospital he took up surgical practice in that city, and soon came to occupy a high place in the profession. He was elected a Fellow of the Royal College of Surgeons in Ireland in 1881, and was its President in 1888–89. For many years he was chief medical officer to the General Post Office, Dublin, and was also surgeon to the Westmorland Lock Hospital. Perhaps because of his large practice he was not an extensive contributor of papers to the medical journals or societies. It is noteworthy, however, that so long ago as 1887 he wrote on the treatment of ununited fractures by metal screw-taps. Whatever he wrote was clear and cogent, and bore the impress of firm conviction. He was also a careful and successful teacher. He retired from active work at the City of Dublin Hospital some 15 years ago. Dr. Fitzgibbon was, like other members of his family, possessed of a striking individuality, which impressed itself on all who knew him. His independence of mind and courage in expressing his opinions commanded universal respect. By his more intimate friends he was regarded with a very deep affection. He leaves a large family, his eldest son being a member of the medical profession.

THE NATIONAL INSURANCE ACT.

THE BRITISH MEDICAL ASSOCIATION'S LETTER TO THE COMMISSIONERS.

THE newly appointed State Sickness Insurance Committee of the British Medical Association, in accordance with the instructions given by the Representative Body, drew up the following letter last week, and forwarded it to the secretary of the National Health Insurance Joint Committee:—

SIR,—I am instructed to inform you that at the Special Representative Meeting of the British Medical Association, held at the Guildhall, February 20-22, the following resolution was unanimously passed:—

"That this Representative Meeting direct the Council to inform, in plain and unmistakeable language, the Commissioners appointed under the Insurance Act, 1911, that unless the *minimum* demands of the Association be embodied in the regulations to be issued by the Commissioners, in such a manner as shall be effectual and permanent with a view to having the same embodied in an amending Act, it is the intention of the British Medical Association to call upon all its members and upon all other medical practitioners to decline to form panels or undertake any other medical duties which may be assigned to them under the Act, in conformity with the undertaking which has already been signed by over 26,000 medical practitioners."

I am to point out to you that the *minimum* demands of the Association mentioned in the above resolution comprise:—

1. An income limit of £2 a week for those entitled to medical benefit.
2. Free choice of doctor by patient subject to consent of doctor to act.
3. Medical and maternity benefits to be administered by Insurance Committees and not by Friendly Societies. In connexion with the question of the method of administration of medical benefit, the Representative Meeting resolved that all questions of professional discipline should be decided exclusively by a body or bodies of medical practitioners, and that the power of considering all complaints against medical practitioners should be vested in the local Medical Committee with a right of appeal to a Central Medical Board to be appointed for that purpose.
4. The method of remuneration of medical practitioners adopted by each Insurance Committee to be according to the preference of the majority of the medical profession of the district of that Committee.
5. Medical remuneration to be what the profession considers adequate, having due regard to the duties to be performed and other conditions of service.

After careful consideration the Representative Meeting resolved that the policy of the Association be to claim 8*s*. 6*d*. as a *minimum* capitation fee, not including extras and medicine, for members of approved societies, and to claim the recognition of payment per attendance, in which case the fees must be on such a basis as shall be deemed an equivalent by the State Sickness Insurance Committee with recognition of a £2 *maximum* income limit.

6. Adequate medical representation among the Insurance Commissioners, in the Central Advisory Committee, and in the Insurance Committees, and statutory recognition of a local Medical Committee representative of the profession in the district of each Insurance Committee.

On behalf of the British Medical Association I am instructed to lay these important points before you and to inform you that they constitute the irreducible *minimum* demanded by the Association.

Another subject which received the special attention of the Representative Meeting was the question of dispensing. The Association is of opinion that dispensing, as hitherto, should be done or arranged for by the medical practitioner for his own patients should he so desire, payment to be made according to the scale of prices fixed by the Insurance Committee in accordance with the terms of the Act.

I am, &c.

ALFRED COX, Acting Medical Secretary.

British Medical Association, February 29, 1912.

CITY OF LONDON AND EAST LONDON DISPENSARY.—The report and statement of accounts of this institution for the year 1911 has just been issued. The number of attendances again shows an increase over previous years, being 2950 in excess of those for the year 1910. The total was 114 212, of which number 6903 were free. The receipts from subscribing members were £2682 14*s*. 6*d*., being £28 in excess of those for the previous year. The donations and subscriptions amounted to £93 14*s* 6*d*. Subscriptions and donations may be sent to the bankers, Messrs. Barclay and Co., Limited, of 54, Lombard-street, E.C., to any member of the committee, or to the secretary at his offices, 58, Lombard-street, E.C.

Medical News.

Her Majesty the Queen will pay an informal visit of inspection to the Barnato Joel Charity and Cancer Research Institution on Wednesday, March 27th.

LISTER INSTITUTE OF PREVENTIVE MEDICINE.—In the lecture theatre of this institute Dr. William Nicoll will give a series of seven lectures on Helminthology on Tuesdays and Fridays at 5 P.M., commencing on March 19th.

THE Hunterian Society's silver medal awarded annually for the best original essay submitted by a general practitioner has been won by Dr. Arthur Goulston, of Heavitree, Exeter, for his essay on "The Use of Sugar in Heart Disorders."

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—At the last council meeting of this association, held at 34, Copthall-avenue, London, E.C., Dr. D. R. Balding presiding, the honorary secretary, Dr. Major Greenwood, reported that an answer had been received from the Local Government Board to the two questions submitted by the council respecting the statistics required in the early part of last November from Poor-law medical officers. The two questions were: 1. Did the Local Government Board consider that under Article 205 of the General Order of 1847, duties such as these were included? 2. In the event of boards of guardians being willing to pay an extra fee for the work would the upper Board sanction it? The answer to (1) was in the affirmative, and with regard to (2), the Board would be ready to sanction extra payment for the work if requested by boards of guardians. It was thought by the council that Poor-law medical officers would gain little benefit from this concession, as few boards of guardians could be got to make the request. The answer of the Chancellor of the Exchequer to their application for a clause in the National Insurance Act to protect Poor-law medical officers of more than 20 years' service from loss that might accrue to them through that measure in respect to their superannuation was considered. The Chancellor suggested that the better course was to communicate in the first instance with the Local Government Board. It was generally considered that this suggestion, as it necessitated an amendment of the Superannuation Act, was an evasion. The honorary secretary submitted the details of a serious breach of the Poor-law Orders which the Winchester guardians had been guilty of, and which had been condoned by the Local Government Board. These guardians had advertised for a medical officer for the Micheldever district, stating that he would only be appointed for three years. Dr. P. E. Todd had been elected on the terms of this advertisement, but he was unaware that it was contrary to the Medical Appointments Order of May, 1857. Article 2 of that Order laid down that where a medical officer resided in his district he should be entitled to be appointed permanently. As Dr. Todd resided in his district he was entitled to a permanent appointment. The Winchester guardians were carrying on a crusade against all permanent appointments, wishing to have their officers entirely in their own hands, and although the Local Government Board had at first refused its sanction to the appointment of Dr. Todd for only three years, it has been induced to withdraw its objection. In reply to a letter the Local Government Board stated that in view of the reasons brought forward by the guardians it had agreed not to offer objection to the appointment. Dr. Major Greenwood, in criticising the reply, said that in a newspaper report of the meeting of the guardians nearly every speaker definitely stated that the reason was that the Board objected to *permanent appointments*. The fact of the advertisement made the matter worse; for it flagrantly contravened the Medical Appointments Order. The council thought that this was a case of considerable gravity. It threatened that security of tenure so long enjoyed by Poor-law medical officers. Again, was the consent of the Local Government Board accidental, or did it indicate a change of policy with regard to permanent appointments? The honorary secretary was instructed to write again to the Local Government Board, asking if the action of the Winchester guardians in this matter was going to be approved generally. It was also resolved to approach the National Poor-law Officers' Association on the subject, and to request the British Medical Association to take action in the matter. A letter was read from a district medical officer of the Gainsborough Union, relating how he had been deprived of his office in order to add his district on to another neighbouring district to induce a medical practitioner to take the two. The Local Govsrnment Board had been appealed to, but, after expostulating, had consented to the guardians' action.

MIDLAND AND WESTERN COUNTIES OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting was held on Feb. 20th at the Grand Hotel, Birmingham, to found the Midland and Western Counties Obstetrical and Gynæcological Society. The chair was occupied by Mr. Christopher Martin. Mr. H. Beckwith Whitehouse read the notice convening the meeting, and Dr. E. Malins then proposed the motion that an Obstetrical and Gynæcological Society, including the Midland, Eastern, and Western Counties of Great Britain, be now formed. Dr. Malins said that a feeling had long existed that the provinces were not adequately represented in these important matters. In the large area over which it was proposed to form a new society there were large towns and a wide district where much activity was displayed in the pursuit of obstetrical and gynæcological knowledge. There were here comprised teaching centres and a number of hospitals where much valuable work was done, and a large amount of treatment carried on without due recognition or opportunity of record. It had been found that much time had been taken up with often inconvenience in journeying to and from London, and outside that great centre there was a mass of material which could not be utilised to the extent deserving of its interest and value. The provinces were overshadowed by the metropolitan societies, in which progress and interchange of opinions were naturally gathered and centralised; hence those outside had not the same proportionate advantages. This want would be supplied by the new society in which it was confidently expected there would be a willing response to the facilities afforded by the mutual coöperation of its members. The motion was seconded by Dr. John T. Hewetson and carried unanimously. Mr. J. Furneaux Jordan proposed that the society be called the "Midland and Western Counties Obstetrical and Gynæcological Society." He thought that the addition of the word "Eastern" would unnecessarily lengthen an already long title, but he hoped the society would not exclude the admission of members practising in the eastern counties. Dr. Beatrice Webb seconded the motion, which was carried unanimously. Mr. E. Tenison Collins (Cardiff), in proposing that the object of the society should be the promotion of the science and art of obstetrics and gynæcology, said that he welcomed the formation of the society, emanating as it did from Birmingham, the original home of English gynæcology. Mr. Furneaux Jordan seconded the motion. Mr. Martin then proposed that the government of the society should be vested in the office bearers, who should be elected from among the members, and should consist of a president, three vice-presidents, a treasurer, general secretary, local secretaries, and a council of not less than six. It was further proposed that the officers and council should be elected annually by ballot. Mr. Beckwith Whitehouse seconded the motion. The election of officers and council for 1912–13 then took place, when the following were unanimously elected:—President: Dr. Malins (Birmingham). Vice-Presidents: Mr. Martin (Birmingham), Dr. Walter C. Swayne (Bristol), and Mr. H. T. Hicks (Derby). Honorary treasurer: Dr. C. E. Purslow (Birmingham). Honorary general secretary: Mr. Beckwith Whitehouse (Birmingham). Honorary local secretaries: Mr. D. C. Rayner (Bristol) and Dr. T. C. Clare (Leicester). Other members of council: Dr. F. L. Harman Brown (Coventry), Mr. Tenison Collins (Cardiff), Dr. Wheelton Hind (Stoke-on-Trent), Dr. William Smith (Nottingham), Dr. Thomas Wilson (Birmingham), and Dr. C. J. Williams (Woodhall Spa). The President then took the chair and proposed that the society should be itinerant, and that arrangements for the meetings should be placed in the hands of the council. This was seconded and carried unanimously. It was further resolved that the

proceedings at each meeting should consist in the exhibition of living cases, specimens, and instruments, and the reading and discussion of "short communications" and papers. The secretary was asked to approach the editorial committee of the *Journal of Obstetrics and Gynæcology of the British Empire* with a view to the publication of the proceedings and papers read before the society. A pathological subcommittee was also formed, to which specimens of unusual interest or complexity may be submitted for report. The following were unanimously elected to serve on this committee for the year 1912-13: Professor R. F. C. Leith, Dr. John T. Hewetson, and Dr. L. G. J. Mackey. The committee has power to coöpt other members. Mr. Martin then moved that the council be empowered to draw up a set of rules and be instructed to submit the same to the next general meeting of the society. The motion was seconded by Dr. Wilson and carried unanimously.

TENURE OF OFFICE OF SANITARY OFFICIALS.—At the last meeting of the executive committee of the Mansion House Council on Health and Housing a report on the tenure of office of sanitary officials in and around London was received, and after consideration the following resolutions were passed:—

This Council are of opinion that it would be in the interests of the public and lead to the better administration of the laws relating to sanitation if the medical officers of health in Greater London who devote the whole of their time to public work, and all sanitary inspectors and inspectors of nuisances in London and Greater London respectively, were, after any necessary period of probation, appointed to their offices without limit of time, and if they were not liable to be removed from their office except by the Local Government Board or by their respective councils with the consent of the Local Government Board.

That this resolution be communicated to the Local Government Board, with the request that they will give the matter their consideration and take such steps as may seem to them suitable to give effect to this recommendation.

THE After-Care Association for Poor Persons Discharged Recovered from Asylums for the Insane held its annual meeting on Feb. 28th, at Queen's Gate Hall, South Kensington, when Lord Claud Hamilton presided. The report and balance-sheet for the year 1911 showed a very satisfactory increase, not only in contributions received, but also in cases successfully helped, these having far exceeded the number dealt with in any previous year. An urgent appeal was made for increased funds to carry on and extend the work of this, the only association of its kind in the United Kingdom.

CHELSEA CLINICAL SOCIETY.—The annual dinner of this society will take place at the Richelieu Hotel, Oxford-street, on Wednesday, March 20th, at 7.45 for 8 o'clock punctually. Professor Einthoven will be present by request. Tickets, price 7*s.* 6*d.*, may be obtained from the senior secretary, Dr. J. F. Halls Dally, 16, Lower Seymour-street, Portman-square, London, W.

GALTON EUGENICS LABORATORY (UNIVERSITY OF LONDON).—A lecture on Tuberculosis: Heredity and Environment, will be delivered by Professor Karl Pearson, F.R.S., in the Galton Eugenics Laboratory, University College, London, on Tuesday, March 12th, at 8.30 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN.—The annual general meeting of governors of this charity will be held in the board room of the hospital on Tuesday next, March 12th, at 5 P.M.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

National Insurance Lecturers.

IN the House of Commons on Thursday, Feb. 29th, certain aspects of the action of the Insurance Commissioners in appointing lecturers to explain the working of the National Insurance Act were criticised. Mr. H. LAWSON raised one point in the course of the debate which has interest to the medical profession. How, he asked, were those lecturers to deal with the medical benefit. They could not, he pointed out, explain what was contemplated, because the Insurance Commissioners had not come to terms with the medical profession. In his opinion it was doubtful whether they could come to terms. It was a very serious thing that the lecturers should be asked to deal with the claims of the medical men without knowing in what way the question would be met. Mr. MASTERMAN, who replied on behalf of the Government, did not deal at length with the point Mr. LAWSON raised. He merely referred the House to an answer which he gave to Sir PHILIP MAGNUS on Feb. 26th. That answer stated that the lecturers had been given careful instructions to explain the Act as it stood on the statute book, and the alternative attitudes which the Insurance Commissioners were empowered to adopt towards medical benefit.

Asylum Officers' Superannuation Bill.

Sir CHARLES NICHOLSON has introduced a Bill in the House of Commons "to amend the Asylum Officers' Superannuation Act, 1909." It was read a first time. This Bill is "backed" by Colonel LOCKWOOD, Mr. CROOKS, Mr. MILLAR, Mr. HARRIS, and Mr. NANNETTI.

Royal Commission on Sewage Disposal.

A sum of £3807 is proposed in the estimates for 1912-13 for the expenses of the Royal Commission on Sewage Disposal. Seven reports have been made by this commission since it was appointed in 1898. Its members are now investigating the question of the disposal of trade effluents (other than distillery effluents) when not mixed with sewage. Their observations on the effects of discharging effluents of known composition into streams are now nearly complete, and they are considering the data thus obtained in connexion with the question of standards and tests.

Miners' Phthisis.

It is stated in the estimates for temporary Commissions for the year 1912-13 that the special research which will be necessary in connexion with the important branch of the inquiry of the Royal Commission on Mines, dealing with miners' phthisis, may be prolonged. It has therefore been thought desirable to estimate for the whole year.

Royal Commission on University Education in London.

According to a statement made in the estimates for 1912-13 by the secretary of the Royal Commission on University Education in London the Commission has still a considerable amount of evidence to hear upon several different parts of its inquiry. It is not at present possible to say anything definite with regard to its probable duration.

The Health of the Army.

Colonel SEELY, the Under-Secretary of State for War, in his general statement of army policy to the House of Commons on Monday, March 4th, made an encouraging statement on the improved health of the British soldier. "The sobriety of the army," he said, "has increased out of all knowledge. In 1889, 688 men were admitted to hospital suffering from alcoholism. In 1903 the number had sunk to 169. In 1910, the last year for which we have figures, the number was 37. That is a drop from 688 to 37. The admissions to hospital for certain preventable diseases, which have done so much harm to the army in many ways, have been reduced, I am glad to tell the House, in quite an extraordinary degree. During the last seven years they have been reduced by more than half, and the deaths have been reduced to a quarter of what they were seven years ago."

HOUSE OF COMMONS.

WEDNESDAY, FEB. 28TH.

Voluntary Insurers and Medical Benefit.

Sir PHILIP MAGNUS asked the Secretary to the Treasury whether, having regard to the fact that under the National Insurance Act as it stood any person who, having been compulsorily insured for a period of five years, might become and remain a voluntary insurer entitled to medical benefit at such annual rate as might be arranged, be his income what it might, it was proposed, by regulation of the Commissioners or otherwise, to fix any limit of income beyond which such insured person should cease to be entitled to medical benefit at the common rate.—Mr. MASTERMAN replied: I beg to refer the honourable Member to Section 15, Subsection 3, of the Act. An income-limit which may be fixed under that subsection would, of course, apply to the particular class of voluntary contributors to whom he refers.

Vaccination Officers and Exemption Certificates.

Mr. TOUCHE asked the President of the Local Government Board whether he could give any indication, by way of percentage or otherwise, of the approximate reduction in each year since Jan. 1st, 1908, in the remuneration of vaccination officers arising from exemption certificates; and whether he proposed to take any steps to deal broadly and comprehensively with the cases of officers who had suffered serious pecuniary loss, and place their future remuneration on a satisfactory basis.—Mr. BURNS answered: Owing to the variety in the fees paid to vaccination officers in different districts I am not able to indicate the percentage reduction of the remuneration of these officers since 1907, but the number of vaccinations in England and Wales has declined from 696,147 in 1907 to 531,567 in 1910. I am endeavouring to deal with the cases of officers who have suffered serious primary loss.

Vaccination Exemptions.

Mr. STEWART asked the President of the Local Government Board whether he could state the number of exemptions granted against vaccination in 1908, 1909, 1910, and 1911, respectively; and the number of unvaccinated persons in the United Kingdom, as far as could be estimated, at the present moment.—Mr. BURNS answered: The number of exemptions received by vaccination officers in England and Wales was as follows: 1908, 162,799; 1909, 190,689; 1910, 230,947; 1911 (first half), 119,335. There are no data upon which an estimate of the number of unvaccinated persons in the country can be made.

THURSDAY, FEB. 29TH.

Medical Department of Ceylon.

Mr. MACCALLUM SCOTT asked the Secretary of State for the Colonies whether there were any, and, if so, what, appointments in the

Medical Department of the Government of Ceylon which were reserved for Europeans only.—Mr. L. HARCOURT replied: I am not aware that any posts are exclusively reserved for Europeans, though it is considered desirable to have a certain comparatively small number of European officers in the Medical Department.

Mr. MACCALLUM SCOTT: May I take it, then, that there are no individual posts which are exclusively reserved for Europeans?—Mr. HARCOURT: That is my impression.

A Case of Anthrax.

Mr. JOWETT asked the Secretary of State for the Home Department whether he was aware that another death had occurred from anthrax, contracted at the firm of Messrs. Campbell and Harrison, woolcombers, of Shipley, a branch of Woolcombers, Limited, and, if so, what he intended to do in the matter, having regard to the frequent loss of life from this cause at the firm in question.—Mr. MCKENNA replied: I have received full reports of this case. The man was employed in card grinding—a process which is not dealt with in the regulations, and which until recently has not been regarded as presenting specific danger of anthrax. It is evident, however, from the circumstances of this case that measures will be necessary for protecting the workers against any dangerous dust which may be given off during the process, and I am advised that the use of appliances similar to those being now generally installed in the carding-rooms of Lancashire cotton mills should form an effective safeguard. Instructions will be given to the inspector to take up the matter at once with the firm in question.

Mr. C. BATHURST: In view of the steady increase in this fatal disease amongst birds and farm animals and human beings, will the right honourable gentleman direct an inquiry to see what is the best and most effective disinfectant against its spread?—Mr. MCKENNA: I am not sure whether that question ought not really to be addressed to my right honourable friend the President of the Board of Agriculture.

Vaccination Topics.

Mr. LANSBURY asked the President of the Local Government Board whether the action of the Metropolitan Asylums Board, in declining to receive boys recommended by the Southwark board of guardians on board the training ship *Exmouth* unless they had been vaccinated, had his sanction, seeing that this ignored conscientious objection, as recognised by law, and reinstated compulsion; and, if not, whether he would take steps to restore freedom of conscience to persons under the control of the Metropolitan Asylums Board.—Mr. BURNS wrote in reply: I am advised that the Metropolitan Asylums Board have a discretion whether they will admit an unvaccinated boy to the ship.

Mr. COTTON asked the right honourable gentleman whether the lymph used in cases of vaccination in Ireland was taken from calves which had not been slaughtered, while in England the same Board insisted upon lymph being taken from calves which were afterwards slaughtered and a post mortem made with a view to seeing whether such calf or calves were affected with tuberculosis or otherwise.—Mr. BURNS (in a written answer) replied: The Local Government Board in Ireland, on the recommendation of their bacteriologist, have sanctioned the adoption of a system under which all calves used for lymph production at the National Vaccine Institute, Dublin, shall be subjected to the tuberculin test instead of being slaughtered as formerly, and a post-mortem examination held. It is considered that the new system would be less costly and more efficient, and that the tubercular foci that might escape detection at autopsy would be at once revealed on application of the tuberculin test. The Board have arranged that the bacteriologist shall personally supervise the processes and methods of tuberculin testing, and see that they are carefully carried out in the case of every calf the lymph of which is to be used for vaccination purposes. The facts as regards England are correctly stated.

MONDAY, MARCH 4TH.

Anthrax.

Captain MURRAY asked the President of the Board of Agriculture whether, in view of the uncertainty that prevailed on the subject of anthrax, he would consider the advisability of appointing a committee to inquire into anthrax and its causes.—Mr. RUNCIMAN answered: I do not think that the occasion has arisen for the appointment of a Departmental Committee. Careful and continuous investigations are being carried on by the veterinary staff of the Board, and I think that for the present we may be content to await the issue of their investigations and the results of the operation of the anthrax order of 1910, which has been in force for little more than 12 months.

Mr. CHARLES BATHURST asked the right honourable gentleman whether, in view of the recent serious outbreak of anthrax among both human beings and farm animals in this country, and of the opinion generally held by the veterinary profession that the disease was mainly traceable to imported hides and fleeces, he would take steps to secure the thorough disinfection by means of formalin, mercuric chloride, or other searching disinfectant, of such goods either prior to their embarkation abroad or to their debarkation at a British port.—Mr. RUNCIMAN answered: I anticipate that the report of the Departmental Committee on foot and mouth disease will be of considerable assistance to the Board in determining whether the disinfection of imported hides and fleeces is necessary and practicable, and I think it desirable, therefore, to await the issue of that report before taking any action in the matter.

Industrial Poisoning.

Mr. RAMSAY MACDONALD asked the Secretary of State for the Home Department whether he could give the number of cases of industrial poisoning reported in the period 1910 to 1912.—Mr. MCKENNA answered: The cases of industrial poisoning by lead, mercury, arsenic, and anthrax in factories and workshops notified under Section 73 of the Factory Act numbered in 1910, 573, of which 48 were fatal; in 1911, 755, of which 44 were fatal; in January of this year 42, of which 7 were fatal. There have been no cases of phosphorus poisoning since 1909. Cases of industrial poisoning from other causes and in other industries are not required to be notified to the Home Office.

The Inquiry into Patent Medicines.

Mr. LYNCH asked the Secretary of State for the Home Department whether he had decided on the constitution of the Joint Committee to be appointed to inquire into the traffic in patent medicines and allied matters; and whether, in view of the difficulty of disassociating the question of the sale of such drugs from that of the illicit practice of medicine, he would consent to enlarge the scope of inquiry so as to include these matters in the terms of reference.—Mr. MCKENNA said in reply: The answer to the first part of the question is in the negative. As regards the second part, I would refer the honourable member to the answer given to a similar inquiry on Dec. 13th last.

TUESDAY, MARCH 5TH.

Illness at Osborne College.

Mr. HUNT asked the First Lord of the Admiralty whether there were at present at Osborne College two cases of typhoid fever, two of bronchitis, one of pneumonia, and one of diphtheria; whether there were in the College altogether 70 people on the sick-list; and, if so, what steps were being taken to prevent the various diseases from spreading.—Mr. CHURCHILL replied: There were 32 cases of boys under medical treatment at Osborne College on March 3rd, 1912. Of these, one was a case of enteric fever, now convalescing; three cases of pneumonia; one of chicken-pox. The remaining 27 are minor diseases and injuries. There were no cases of diphtheria or bronchitis.

WEDNESDAY, MARCH 6TH.

Housing of London University.

Sir PHILIP MAGNUS asked the Prime Minister whether the Government had made itself responsible for the housing of the University of London throughout its history; whether he was aware that in the Treasury Minute, dated Feb. 16th, 1899, the liability to provide a dignified and suitable home for the University, and also to make such provision as might thereafter be needed for the full extension and development of the University under the statutes and regulations made by the Commissioners appointed by the Act of 1898 was acknowledged; and what steps His Majesty's Government proposed to take in the matter, in view of the present unsatisfactory accommodation for the University as disclosed in the Report of the Royal Commission on University Education in London, issued on Dec. 15th, 1911.—Mr. ASQUITH said, in reply: The Government have as a matter of fact provided accommodation for the London University throughout its history. The Treasury Minute cited by the honourable Member was written before the removal of the old University to South Kensington and refers to the possibility of an arrangement which was actually carried out between the authorities of the Imperial Institute and the Treasury. It must not be construed as admitting liability on the part of His Majesty's Government to provide for all possible requirements of the University in the future. The recent report of the Royal Commission points out that the University must depend to a large extent upon private endowments for its full development. The Government do not think that it would be opportune to take any step in connexion with the present accommodation for the University before the Final Report of the Royal Commission has been issued.

BOOKS, ETC., RECEIVED.

BERGMANN, J. F., Wiesbaden.

Zur J.-K.-Behandlung. Eine kritische Uebersicht der vorliegenden J.-K.-Literatur nebst vergleichend tabellarischer Zusammenstellung der therapeutischen J.-K., Tuberkulin-Heilstätten und klimatischer Heilstätten-Erfolge. Von Sophie Fuchs-Wolfring, Paris, frühere Mitarbeiterin von Dr. Carl Spengler in Davos. Price M 2.40.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

CATER, J., M.D. Brux., L.S.A., has been appointed Assistant Medical Officer of Health for Coventry.

COOK, Miss G. H., has been appointed Assistant Medical Officer at Headquarters of the General Post Office.

FERRAN, F. P., M.B., B.S. Belf., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Foxford District of the county of Mayo.

GREAVES, H. G., M.B., B.C. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Oxted District of the county of Surrey.

GRIFFIN, W. R., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Tavistock District of the county of Devon.

KENDALL, FRANK EDWARD, M.B., Ch.B. Lond., has been appointed Junior Assistant Medical Officer at the Oxford County Asylum.

KING, BARTY, M.D. Edin., M.R.C.P. Edin., has been appointed Honorary Physician for Diseases of the Chest to St. Pancras Dispensary.

LAKIN, C. ERNEST, M.D. Lond., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed Assistant Physician to the Middlesex Hospital.

LITTLEWOOD, MARTIN W., M.R.C.S., L.R.C.P. Lond., B.S. Lond., has been appointed House Surgeon at the Hampstead General Hospital.

OGILVY, DAVID, M.D., B.Ch., B.A.O Dub., has been appointed Medical Superintendent of the Long Grove Asylum.

ROBINSON, A. L., M.B., B.S. Lond., has been appointed House Physician at University College Hospital.

SIBLEY, W. KNOWSLEY, M.D. Cantab., M.R.C.P. Lond., has been appointed Physician to St. John's Hospital for Diseases of the Skin.

SPROULL, J., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Luddenden District of the county of Yorks, West Riding.

STAUNTON, M. D., L.A.H. Dub., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Swineford District of the county of Mayo.

TANNER, HAROLD H., M.B., B.S. Lond., has been appointed House Physician at the Hampstead General Hospital.

WALTON, ALBERT J., M.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Evelina Hospital for Children, Southwark.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNSLEY, BECKETT HOSPITAL.—Second House Surgeon, unmarried. Salary £100 per annum and all found.

BEDFORD COUNTY HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and laundry.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Second and Third House Surgeons. Salaries £80 and £75 per annum respectively, with board, rooms, and laundry.

BRADFORD CITY BABIES' WELCOMES.—Medical Officer (female). Salary £250 per annum.

BRADFORD ROYAL INFIRMARY.—Two House Surgeons, unmarried. Salary £100 per annum, with board, residence, and washing.

BRENTFORD UNION INFIRMARY.—First Assistant Medical Superintendent, unmarried. Salary £185 per annum, with apartments, rations, washing, &c.

BRIGHTON AND HOVE HOSPITAL FOR WOMEN.—House Surgeon, unmarried, for six months. Salary £80 per annum, with apartments, board, light, attendance, &c.

BRISTOL CITY AND COUNTY.—Female Medical Inspector of Midwives and Health Visitors. Salary £100 per annum.

BRISTOL EYE HOSPITAL.—House Surgeon. Salary £80 per annum, with board and residence.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Junior Resident Officer. Salary £90 per annum, with rooms and attendance.

BURY ST. EDMUNDS, WEST SUFFOLK GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and laundry.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—House Physician. Salary £80 per annum, with board, residence, and laundry.

CANCER HOSPITAL (FREE), Fulham-road, S.W.—Assistant Pathologist. Salary £350 per annum. Also House Surgeon for six months. Salary £70 per annum.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £150 per annum, with apartments.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant for three months.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £80 per annum, with board, lodging, and washing.

CLIFTON, YORK, NORTH RIDING LUNATIC ASYLUM.—Assistant Medical Officer. Salary £150 per annum, with board, apartments, washing, and attendance.

DORCHESTER COUNTY ASYLUM.—Second Assistant Medical Officer. Salary £200 per annum, with board, &c.

DORCHESTER, DORSET COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, &c.

DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Salary £100 per annum, with board, residence, attendance, and washing.

DUNDEE ROYAL INFIRMARY.—Medical Assistants.

EDMONTON UNION INFIRMARY, Bridport-road, Upper Edmonton.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with residential allowances.

FRIMLEY, BROMPTON HOSPITAL SANATORIUM.—Medical Superintendent. Salary £500 per annum, with board and residence.

GLOUCESTER, GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway, London, N.—House Surgeon and House Physician for six months. Salary at rate of £40 per annum in each case, with board, lodging, and laundry.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with rooms, board, and washing.

HEREFORDSHIRE GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £120 per annum, with board, apartments, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.—Assistant Physician.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—House Surgeon, unmarried, for six months. Salary £30, with board, residence, &c. Also Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board and residence, &c.

JERSEY POOR-HOUSE AND INFIRMARY (HÔPITAL-GÉNÉRAL).—Medical Officer. Salary £250 per annum.

KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, apartments, and laundry.

KENSINGTON AND FULHAM GENERAL HOSPITAL, Earl's Court, S.W.—Assistant Physician.

KING'S COLLEGE HOSPITAL, London.—Clinical Assistant.

LARBERT, STIRLING DISTRICT ASYLUM.—Second Assistant Medical Officer. Salary £140 per annum, with board, lodging, and laundry.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100 per annum, with board and lodging.

LIVERPOOL DISPENSARIES.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

LIVERPOOL HOSPITAL FOR CANCER AND SKIN DISEASES, Myrtle-street.—Honorary Surgeon.
LIVERPOOL ROYAL INFIRMARY.—Dental Surgeon.
MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board and residence.
METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Physician.
MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Senior and Junior House Surgeon for six months. Salaries at rate of £100 and £85 per annum respectively, with board, attendance, and laundry.
NAVAL FORCES IN THE UNITED KINGDOM.—Dental Surgeon. Salary £1 per day.
NEW HOSPITAL FOR WOMEN.—Female Senior Assistant. Also Clinical Assistant.
OXFORD, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Casualty Officer, unmarried, for six months. Salary at rate of £80 per annum, with board, &c.
OXFORD UNITED DISTRICTS.—Medical Officer of Health. Salary £400 per annum.
QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Surgeon-in-Charge of Ear, Nose, and Throat Department.
ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.
ROYAL EAR HOSPITAL, Soho.—House Surgeon, non-resident. Salary £40 per annum. Also Honorary Assistant Anæsthetist.
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Senior Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.
ROYAL HALIFAX INFIRMARY.—Senior House Surgeon, unmarried Salary £120 per annum, with residence, board, and washing. Also Third House Surgeon, unmarried. Salary £80 per annum, with residence, board, and washing.
ROYAL NAVAL MEDICAL SERVICE.—Fifteen Appointments.
ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—Demonstrator of Physiology.
SALFORD ROYAL HOSPITAL.—House Surgeon. Salary at rate of £75 per annum. Also Junior House Surgeon and Casualty House Surgeon. Salaries at rate of £65 per annum. All for six months, with board and residence.
SHEFFIELD UNION HOSPITAL, Firvale.—Senior Resident Assistant Medical Officer, unmarried. Salary £130 per annum, with apartments, rations, &c.
SHEFFIELD UNIVERSITY.—Demonstrator in Experimental Physiology. Salary £200 per annum.
SHREWSBURY, SALOP INFIRMARY (COUNTY HOSPITAL).—House Physician Salary at rate of £70 per annum, with board and apartments.
SOUTHAMPTON WORKHOUSE INFIRMARY, Shirley Warren.—Resident Assistant Medical Officer. Salary £130 per annum, with apartments, rations, washing, and attendance.
STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—House Physician. Salary £82 per annum, with board, residence, and laundry.
SUNDERLAND ROYAL INFIRMARY.—Junior House Surgeon for six months. Salary £80 per annum, with board, residence, and laundry.
UNIVERSITY COLLEGE HOSPITAL, Gower-street, W.C.—Assistant Surgeon.
VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Radiographer. Salary £75 per annum.
WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, &c., 73, Welbeck-street, W.—Resident House Physician for six months. Salary at rate of £50 per annum. Also Clinical Assistants.
WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer. Salary at rate of £100 per annum, with board, rooms, and laundry. Also Resident Surgical Officer. Salary £125 per annum, with board, apartments, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Blisworth, in the county of Northampton; at Gatehouse, in the county of Kirkcudbright; at Medbourne, in the county of Leicester; at Rye, in the county of Sussex; and at Salisbury, in the county of Wilts.

Births, Marriages, and Deaths.

BIRTHS.

DEWEY.—On March 1st, the wife of E. W. Dewey, M.R.C.S., L.R.C.P., of Kingswear, London-road, Portsmouth, of a son.
HUGHES.—On March 3rd, at St. Thomas-street, S.E., the wife of E. C. Hughes, F.R.C.S. Eng., of a son (still-born).
LLOYD-WILLIAMS.—On Feb. 24th, at Sandon, the wife of R. V. Lloyd-Williams, M.B., of a son.
OWEN.—On Feb. 27th, at Grove Lodge, Kingston-on-Thames, the wife of John Griffith Owen, M.R.C.S., of a son.
YULE.—On March 2nd, at St. Albans-villas, Highgate-road, N.W., Marie, the wife of Bransby Yule, M.R.C.S., L.R.C.P., of a daughter.

DEATHS.

DODD.—On March 1st, at Walthamstow, Henry Noel Nelthorpe, L.R.C.P. & S. Edin., only son of Henry Alnutt Dodd, aged 43 years. R.I.P.
ELLIOT.—On March 2nd, at Belvedere-road, Upper Norwood, George Stanley Elliot, M.R.C.P., F.R.C.S. Edin., aged 68 years.
MCNALTY.—On March 1st, at Lansdowne-road, Blackheath, George William McNalty, C.B., M.D., F.R.C.S. Irel., Lieutenant-Colonel late Army Medical Staff, in the 75th year of his age.
SIMPSON.—On Feb. 28th, at Cumberland-terrace, Regent's Park, Frank Simpson, Surgeon-Major, retired, R.A.M.C.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE GALTON LECTURES.

QUITE recently the Eugenics Education Society has endeavoured to awaken public interest in this country in eugenics as a school subject. That it can be made interesting, as well as instructive, is shown by the two lectures with which Professor Karl Pearson opened the course of Galton lectures at University College recently, while if we eliminate the allusions to specific individuals the main contention of the lecturer could be understood by many children. His purpose was to show that Galton owed his mental characteristics more to ancestry than to environment, thus using the founder of the science of eugenics as an example of its teachings. Beginning with a brief reference to the writings of Galton, in which, while fully appreciating the modifications due to environment, he holds that mental and physical characteristics are alike inherited, and that "when nature and nurture compete for supremacy on equal terms, the former proves the stronger," Professor Pearson showed on the screen many portraits of the Galton, Darwin, and other families from which Sir Francis Galton was descended. Professor Pearson then dealt with the genealogical charts with which his audience had been supplied, the drawing up of which must have entailed much labour. The lecturer referred to the difficulty of obtaining trustworthy information in the tracing back of a pedigree through the squirearchy to the yeoman class, which can always be followed until about A.D. 1600 by the church registers and until A.D. 1500 through wills; beyond that time the difficulties are very great. The charts referred to were three in number. They showed: (1) the direct ancestors of Sir Francis Galton as far as yet traced; (2) a pedigree showing the connexion of the Barclays (Lucy Barclay was the paternal grandmother of Sir Francis Galton) with noteworthy ancestors, including the Frankish kings, the Carlovingians, French kings, and the royal houses of our own country; and (3) the immediate ancestry and collaterals. Emphasising the point that nurture had not very much to do with Galton's development, Professor Pearson alluded to the fact that school life was uncongenial to both Galton and Darwin. The lecturer then commented on the various forebears of Galton—the Saviles, the Sedleys, the Colliers and Colyears, the Barclays and Darwins—and showed how one marriage brought in one dominant factor and another marriage another. Professor Pearson closed his first lecture with an interesting comparison between Darwin and Galton based on the love of travel in the Barclay strain. Darwin accepted a position in the *Beagle* not from an inherent love of travel, but because he wished to add to the stock of scientific knowledge; while Galton, in his works, rushed from point to point, showing here a new field for biologists, here a field for the psychologist, and so on, thus showing the *Wanderlust* even in his writings.

COW-DUNG AS A PREVENTIVE OF PLAGUE.

WE have received a long letter from a Sub-Assistant Surgeon at Baroda on the subject of the washing of the floors of Hindu huts with cow-dung, a proceeding advocated by Dr. C. N. Saldanha for the prevention of plague, and to which reference was made in our columns on Sept. 30th and Oct. 21st last year. In this letter, after discussing certain objections and particularly that arising from the possibility of tubercle bacilli being present in the cow-dung, our correspondent describes the two usual methods in practice of applying the dung to the floors in India, viz., (1) in the form of a thick paste, and (2) by means of a watery solution. In either case it is mixed with some other substance, usually the yellow or black earth (pili or kali mati), and the mucilaginous character of the cow-dung referred to by Dr. Saldanha is chiefly due to this admixture. The first of these methods is carried out at long intervals, extending usually over some months or even years. The thick paste after drying cracks in many places, and these fissures harbour fleas, and possibly other organisms. The second process, that is the washing of the floor with the watery solution of dung, is carried out daily, the woman of the house commonly retaining for use the same filthy rag and earthenware pot for long periods. Our correspondent sees no benefit whatever in either of these methods as regards the prevention of plague, but apprehends, on the other hand, grave danger to the inmates of the house from the tubercle bacilli that may be present in the cow-dung. He does not see much prospect of disinfection of floors in India by pesterine, carbolic acid, or other cheap antiseptic coming into general use. While admitting that, except on the score of expense, cement floors would be the best he recommends a mixture of tar and concrete as being satisfactory for the purpose; but he asks if the readers of THE LANCET can suggest a cheaper substitute, as also a cheap and effective floor-washing disinfectant, so that all grades of the population of India may be able to use it freely.

THE WOMEN'S IMPERIAL HEALTH ASSOCIATION.

WE have received the belated first annual report (1910) of this association, the aim of which is to instruct the women of the Empire in the elementary principles of hygiene, and to disseminate knowledge regarding the care and nurture of children. These ends they propose to accomplish by the organisation of instructive and educational meetings throughout London and the provinces, and the establishment of local branches throughout the Empire; by conducting health caravan tours through the villages and towns of England; the distribution of leaflets; watching legislation on various questions concerning women and children, and similar methods. Over 100,000 children, it is said, die yearly in England and Wales through parental ignorance and neglect. The ignorance of mothers as to their own health and the proper feeding of children is appalling, and many serious disorders are largely due to preventable ignorance. The report recounts the history of the association, which was founded in 1898 as the National Women's Health Association, and has already done good work in the institution of courses of lectures in and around London. Two caravan tours have also been made and have aroused considerable interest among those for whose benefit they were planned. Kinematograph displays illustrative of health matters have also been given in various London parks. Another useful work was the agitation for adequate lavatory accommodation for women. The success of the association is shown by the fact that it has been able to place no less than £1000 towards a reserve fund. The list of officials includes many well-known medical men, Lord Ilkeston, Sir T. Lauder Brunton, Sir Anderson Critchett, Lieutenant-Colonel Sir Joseph Fayrer, R.A.M.C., Sir William Bennett, Dr. Mitchell Bruce, Mr. McAdam Eccles, Dr. Clement Godson, Dr. T. N. Kelynack, Mrs. Scharlieb, M.D., and Dr. G. E. Shuttleworth being vice-presidents, while Mr. E. M. Corner is honorary treasurer. The president is Muriel Viscountess Helmsley, and the secretary Miss R. V. Gill. The offices are at 3, Princes-street, Hanover-square, W.

THE DESTRUCTION OF THE BED-BUG.

IN an annotation in THE LANCET of Feb. 24th, 1912, p. 520, reference was made to the association of the bed-bug with the propagation of kala-azar in India and to the practical application of this fact to preventive measures. Messrs. Edward Cook and Co., Limited, of Bow, London, E., point out, in reference to the methods of extermination of this loathsome insect, that their disinfectant "Cofectant" has been used with great success, quoting an instance of some old houses, the woodwork, lath, and plaster of which were infested with bugs. The Cofectant was applied in the form of spray at a dilution of 1 part in 80 parts of water (1 tablespoonful to 1 quart).

NITROUS OXIDE AND OXYGEN ANÆSTHESIA.

H. P. F.—We believe Dr. Crile's contributions on nitrous oxide and oxygen anæsthesia in major surgery have not been collected into a single volume. The most important papers have been noticed in the Annus Medicus of THE LANCET during the last five or six years under the heading "Anæsthetics." The following papers may be referred to as among the most important: "Note on Nitrous Oxide and Oxygen Anæsthesia in comparison with Ether Anæsthesia" (*Cleveland Medical Journal*, 1909, vol. viii., p. 352), and *Surgery, Gynæcology, and Obstetrics*, August, 1911—London publishers, Baillière, Tindall, and Cox. The transactions of various American societies contain papers or remarks by Dr. Crile upon this subject. These appear in abstract in the *Boston Medical and Surgical Journal*, the *Medical Record*, or the *Journal of the American Medical Association*. Files of these during the last few years should be consulted.

M.R.C.S.—Professor Dieulafoy, of Paris, died on August 16th, 1911.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March, April, and May:—

March 7th–11th (Berlin).—Thirty-third Balneological Congress.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
,, (London).—First Congress of Pure Food and Health Society of Great Britain.
,, 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
April 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
,, 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.
,, 8th–11th (Paris).—Congress of Physiotherapy for French-speaking Physicians.
,, 9th (Berlin).—Eleventh Congress of the German Society for Orthopædic Surgery.
,, 9th–13th (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
,, 10th–13th (Berlin).—Forty-first Congress of the German Surgical Society.
,, 14th (Berlin).—Eighth Congress of the German Röntgen Society.
,, 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
,, 15th–18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
,, 21st–24th (Munich).—Twenty-sixth Meeting of the Anatomical Society.
,, (London, Olympia).—Ideal Homes Exhibition.
Spring (London).—Second Optical Convention.
May 7th–17th (Washington).—Ninth International Red Cross Conference.
,, 23rd–25th (Hanover).—Nineteenth Meeting of the Union of German Laryngologists.
,, 25th–27th (Paris).—International Musical Festival.
Whitsuntide (Portrush).—British Esperanto Congress
May 27th–June 1st (London).—Eighteenth International Congress of Americanists.
,, 29th–31st (Berlin).—Fifteenth Session of the German Society for Gynæcology.
,, (London).—International Horticultural Exhibition.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—L. A. Dunn, James Berry): at 5.30 P.M.

Papers:
Mr. John Murray: Case of Pancreatic Calculus-stone Removed by Operation.
Mr. G. H. Makins, C.B., Mr. Cuthbert Wallace, and Mr. Percy Sargent: Multiple Growths of the Great Gut.
Mr. W. G. Spencer: Hydrocephalus Internus-rupture into the Subdural Space: Intracranial Tension and its Temporary Relief.
Mr. G. H. Makins, C.B.: Multiple Fibromata of the Tunica Vaginalis.

FRIDAY.

OTOLOGICAL SECTION (Hon. Secretaries—Sydney Scott, A. Logan Turner), at 11, Chandos-street, W.: at 5 P.M.

Discussion
On the Value and Significance of Hearing Tests (to be introduced by Dr. Thomas Barr (Glasgow) and Mr. Sydney Scott (London)).

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—G. Harrison Orton, Cecil R. C. Lyster): at 8.30 P.M.

Paper:
Dr. Bordier (of Lyons): The Radio-therapeutic Treatment of Uterine Fibroma.

(Members of the OBSTETRICAL AND GYNÆCOLOGICAL SECTION are specially invited to attend.)

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Mr. T. Walker: The Value of the X Rays in the Diagnosis of Hydronephrosis.—Dr. W. I. Bruce: The X Ray Examination of the Urinary Tract.

CHELSEA CLINICAL SOCIETY, Medical School, St. George's Hospital, S.W.

TUESDAY.—8.30 P.M., Annual Clinical Debate. Paper:—Prof. Sir Clifford Allbutt: The Physician and the Pathologist on Heart Failure. A Discussion will follow in which Sir Lauder Brunton, Dr. S. West, Dr. H. Mackenzie, Dr. C. C. Gibbes, Dr. F. F. Calger and others will take part.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, Lecture Theatre of the Society, 17, Bloomsbury-square, W.C.

TUESDAY.—8 P.M., Mr. R. R. Bennett and Mr. F. W. Gamble: Osmotic Pressure and its Physiological Bearing.—Mr. W. R. Pratt: Analysis of Ferri Citras cum Quinina et Strychnina (communication from the Society's Chemical Research Laboratory).

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—9 P.M., Mr. F. S. Kidd: A Fresh Aid to Prostatectomy.—Prof. W. G. Ball: Non-operative Treatment of Irreducible Herniæ.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Dr. E. K. Martin: The Effects of the Ultra Violet Rays upon the Eye (communicated by Sir J. R. Bradford, K.C.M.G.).—Dr. W. S. Lazarus-Barlow: On the Presence of Radium in Some Carcinomatous Tumours (communicated by Sir J. R. Bradford, K.C.M.G.).—Dr. C. Russ: An Improved Method for Opsonic Index Examinations Involving the Separation of Red and White Human Blood Corpuscles (communicated by Dr. A. D. Waller).—Prof. W. M. Thornton: The Electrical Conductivity of Bacteria and the Rate of Inhibition of Bacteria by Electric Currents (communicated by Prof. C. S. Sherrington).—Mr. E. C. Hort and Dr. W. J. Penfold: A Critical Study of Experimental Fever (communicated by Dr. C. J. Martin).—Mr. S. G. Shattock and Mr. L. S. Dudgeon: Certain Results of Drying Non-sporing Bacteria in a Charcoal Liquid Air Vacuum (communicated by Sir J. Dewar).

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

WEDNESDAY.—5 P.M., Fleet-Surgeon A. Gaskell: Dust Traps nd their Dangers on Board Ships.

OPHTHALMOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Cases and Card Specimens. 8.30 P.M., Papers:—Mr. Herbert: A Distinctive Conjunctival Papule.—Mr. Worth: The Operative Treatment of Conical Cornea.—Mr. H. W. Brailey: A New Cell Proliferant.—Mr. Zohrab: The Relief of Tension in Chronic Glaucoma.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Dr. R. H. Cole: Hypochondriasis, its Significance and Treatment.—Mr. V. Z. Cope: Latent Surgical Disease.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, Royal Army Medical College, Grosvenor-road, S.W.

FRIDAY.—8 P.M., Demonstration of Various Microscopic and Other Specimens of Interest.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

FRIDAY.—5 P.M., Prof. W. G. Ball: Acute Infective Processes Due to the Streptococcus, with Special Reference to the Value of Vaccines and Serums in Treatment.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Dr. T. W. Eden: Clinical Diagnosis of Cancer of the Body of the Uterus.

TUESDAY.—4 P.M., Dr. P. Parkinson: Clinique (Medical). 5.15 P.M., Lecture:—Dr. N. Raw: The Treatment of Local Tuberculous Infections.

WEDNESDAY.—4 P.M., Mr. R. P. Rowlands: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. W. H. Battle: Ventral Hernia.

THURSDAY.—4 P.M., Dr. W. P. S. Branson: Clinique (Medical). 5.15 P.M., Lecture:—Dr. R. Hutchison: Chronic Diarrhœa, its Varieties and Treatment.

FRIDAY.—4 P.M., Mr. H. L. Eason: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Edwards: Clinical Cases.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Bernstein: Blood Examination, Serology.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture V.)

THURSDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. P. Dunn: Infective Cyclitis.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: Cerebral Hæmorrhage.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

TUESDAY.—Clinic: 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Mr. H. W. Carson: Modern Methods of Investigation of the Surgical Disorders of Digestion, their Diagnosis and Treatment.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Mr. H. W. Carson: Modern Methods of Investigation of the Surgical Disorders of Digestion, their Diagnosis and Treatment.

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 2.15 P.M., Special Lecture:—Dr. S. Taylor: Rheumatoid Arthritis.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Dr. Pritchard: The Application of Pathology to Clinical Medicine.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Mr. Kellock: The Radical Cure of Inguinal Hernia.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Collier: Headache.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Collier: Ophthalmoplegia.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Mr. W. Hampson: X Rays, Deeper Tissues.

UNIVERSITY OF LONDON (UNIVERSITY COLLEGE), The Francis Galton Laboratory for National Eugenics.

TUESDAY.—8.30 P.M., Prof. K. Pearson: Tuberculosis—Heredity and Environment. (Lecture VII.)

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street Piccadilly, W.

FRIDAY.—9 P.M., Mr. F. Soddy: The Origin of Radium.

SATURDAY.—3 P.M., Prof. Sir J. J. Thomson: Molecular Physics. (Lecture IV.)

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. W. J. S. Bythell: X Ray Examination of the Stomach with Bismuth. (Post-Graduate Clinic.)

MANCHESTER ROYAL INFIRMARY.

TUESDAY.—4.30 P.M., Dr. H. Griffith: Demonstration of Cases of External Diseases of the Eye.

SALFORD ROYAL HOSPITAL.

THURSDAY.—4.30 P.M., Mr. G. Wright: Cholelithiasis. (Post-Graduate Course).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-

square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (13th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (14th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (16th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

WE much regret that in our Diary of Feb. 24th the dates of two of Professor Flexner's Harben Lectures before the Royal Institute of Public Health were incorrectly stated.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The Milroy Lectures

ON

PARATYPHOID FEVER AND MEAT POISONING.

Delivered before the Royal College of Physicians of London

BY F. A. BAINBRIDGE, M.A., M.D. CANTAB., F.R.C.P. LOND., D.P.H.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF DURHAM.

LECTURE I.

Delivered on Feb. 29th.

MR PRESIDENT AND GENTLEMEN,—I wish to offer my thanks to the College for the honour conferred in appointing me to deliver these lectures.

The clinical features of meat poisoning and paratyphoid fever are very different and at the first glance the two diseases may appear to have little or nothing in common. They are, however, linked together by the fact that they are caused by closely allied organisms.

Some writers have emphasised the clinical difference between them, whereas others have called attention to the similarity (some say the identity) of the bacilli by which they are caused. At the present time the term paratyphoid fever has, therefore, a very different meaning for various writers; and as a result the literature abounds in widely conflicting statements, and the whole subject has been rendered obscure to those who have not made a special study of it.

No serious attempt has yet been made to correlate the clinical and epidemiological characters of meat poisoning and paratyphoid fever with the nature and distribution of the bacilli with which they are associated, and the absence of an authoritative and generally accepted definition of these diseases has inevitably led to confused notions as to their relation to one another. My object in these lectures is to make it clear that they are essentially different diseases, more especially as regards their epidemiology. The recognition of this fact is a necessary preliminary to any advance in their treatment by preventive measures.

I propose first to discuss the classification of the organisms, which are associated with paratyphoid fever and meat poisoning; secondly, to state the definitions of these diseases which appear to accord best with the facts at present available; and thirdly, to describe them separately in order to bring out as sharply as possible the contrast between them. Finally, other definitions of paratyphoid fever will be considered.

HISTORICAL RÉSUMÉ.

It will be convenient, before discussing the different organisms, to give a brief historical *résumé* of the circumstances under which the various bacteria associated with these diseases were isolated, and then to classify them as far as possible.

In 1888, while investigating a large outbreak of meat poisoning Gaertner isolated from the suspected meat and from the spleen of a patient who died a bacillus which he called *B. enteritidis*. Ten years later Durham in England and De Nobele in Belgium independently and almost simultaneously isolated from cases of meat poisoning and from the meat a bacillus closely allied to Gaertner's bacillus. The new organism was called *B. aertrycke*, this being the name of the village in which occurred the outbreak recorded by De Nobele.

In 1896, Acharde and Bensaude isolated from the urine of a case of apparent enteric fever and also from a purulent arthritis following a similar illness a bacillus which they called the *paratyphoid bacillus*. And in 1900–01, Schottmüller obtained from the blood of patients whose symptoms were those of enteric fever two bacilli closely resembling the paratyphoid bacillus of Achard and Bensaude. These two organisms were named by Brion and Kayser B. paratyphosus (A) and B. paratyphosus (B).

The relationship between these four organisms was not at once recognised, but it has been shown during the last few years that they are very closely allied to each other, and also to *B. suipestifer*. This latter organism was isolated by Salmon and Theobald Smith (1885) from an outbreak of swine fever (also known as hog cholera and Schweinpest). They regarded it as the cause of swine fever and for some time its relation to disease in man was entirely unsuspected. It is now well known, through the work of De Schweinitz, Dorset, and McBryde, confirmed by others, that it is not the cause of swine fever, but is merely a secondary invader in that disease.

CLASSIFICATION.

The close relationship between these organisms necessitates the employment of rather laborious methods for their identification. Cultural tests are inadequate and must invariably be supplemented by agglutination and absorption tests.

Cultural Characters.

B. paratyphosus (A) differs culturally from the other members of the group in one important respect—namely, in its action upon litmus milk and in some minor details. The other four organisms are indistinguishable from one another by their cultural characters and their action upon carbohydrates.[1]

Agglutination Tests.

A further means of differentiation is furnished by the use of sera obtained from animals immunised with killed or living cultures of these bacilli. By the aid of such sera B. paratyphosus (A) and B. enteritidis (Gaertner) can readily be distinguished both from each other and from the remaining members of the group. B. aertrycke, B. suipestifer, and B. paratyphosus (B) cannot usually be separated by agglutination tests, although with some sera B. paratyphosus (B) can be distinguished from the other two bacilli.

TABLE I.—*Agglutination Reactions with Sera obtained from Inoculated Animals.*

—	B. paratyphosus (A).	B. paratyphosus (B).	B. suipestifer.	B. aertrycke.	B. enteritidis (Gaertner).
Serum of rabbit inoculated with—					
(1) B. paratyphosus (A).	50,000	< 100	< 100	< 100	< 100
(2) B. paratyphosus (B).	2,000	20,000	10,000	—	< 100
(3) B. suipestifer.	< 100	4,000	5,000	5,000	< 100
(4) B. aertrycke.	< 100	5,000	5,000	5,000	< 100
(5) B. enteritidis (Gaertner).	< 100	< 20	< 20	< 100	50,000

All the observations were made by the macroscopic methods.

Absorption Tests.

The serum of an animal which had been inoculated with a given bacillus often agglutinates, not only that (homologous) bacillus, but also other allied (heterologous) organisms. Sometimes the agglutination titre of the serum for both the homologous and the heterologous organisms is practically the same, and their differentiation by agglutination tests alone is impossible. The same phenomenon is observed in the serum of patients suffering from a particular infection—e.g., enteric fever.

It has been found (Castellani, Boycott, Bainbridge) that under these circumstances a heterologous organism, when added to the serum, absorbs only its own agglutinins, leaving intact the agglutinin for the homologous organism; the addition of the homologous bacillus to the serum removes all the agglutinins formed in the serum in response to its injection into the animal. The absorption method is of very great value for the differentiation of closely allied organisms

[1] The chief characters of these organisms are as follows:—They give rise to the production of acid and gas in broth containing glucose, mannite, dulcite, lævulose, galactose, arabinose, maltose, and sorbite. No apparent change occurs in broth containing lactose, saccharose, salicin, raffinose, and inulin. No indol is formed. Litmus milk inoculated with B. paratyphosus (A) shows slight acidity persisting for three weeks or more; no clot is formed. Litmus milk inoculated with any of the other organisms shows an initial transient acidity not often lasting more than 24 hours. In three to five days the milk is definitely alkaline and at the end of a week intensely alkaline; no clot is formed.

and seems to be particularly useful as regards this group. By its use, B. paratyphosus (B) can be readily distinguished from B. suipestifer and B. aertrycke, whereas the two latter organisms are indistinguishable from one another, as may be seen in Table II.

TABLE II.—*Absorption Reactions.*

—	—	Agglutination limit after absorption.		
		B. paratyphosus (B).	B. suipestifer.	B. aertrycke.
Serum of rabbit inoculated with— (1) B. paratyphosus (B).	Original titre	5000	1000	1000
	Absorbed with—			
	B. paratyphosus (B) ...	200	200	200
	B. suipestifer	4000	< 200	< 200
(2) B. suipestifer.	Original titre	4000	5000	5000
	Absorbed with—			
	B. paratyphosus (B) ...	< 200	4000	4000
	B. aertrycke	< 200	< 200	< 200

Complement Deviation.

Dean has shown that the complement deviation method yields results which correspond exactly to those obtained by the absorption method. He finds that unless a suitable dilution of anti-serum be employed the group antibodies will mask the specific nature of the reaction. They can, however, be removed by absorption previously to carrying out the complement fixation test. Thus, when B. paratyphosus (B) anti-serum is absorbed with an emulsion of paratyphoid (A) bacilli, the latter removes the group antibodies for B. paratyphosus (A), and B. typhosus, but not for B. paratyphosus (B), as is shown by subsequently applying the complement deviation test. Dean found that B. paratyphosus (B) could be differentiated from B. suipestifer and B. aertrycke, but that no difference between the two latter organisms could be demonstrated.

The methods employed for the identification of these bacilli are summarised in Table III. So far as can be judged

TABLE III.—*Method of Identifying the Members of the Salmonella Group.*

Description of organism.	Cultural characters.	Agglutination test.	Absorption test.	Complement deviation test.
(1) B. suipestifer or aertrycke.	Identical.	Usually indistinguishable.	Differentiated by this test.	Can all be differentiated.
(2) B. paratyphosus (B).				
(3) B. enteritidis (Gaertner).		Stands alone.	—	
(4) B. paratyphosus (A).	Differs from the others.	Stands alone.	—	

at present, B. suipestifer and B. aertrycke are indistinguishable from one another, and must be regarded as a single organism which has acquired two names. For several reasons it is preferable to use the name B. suipestifer rather than B. aertrycke. The other three organisms can be readily differentiated both from one another and from B. suipestifer.

The Salmonella Group.

I propose to describe these bacilli, including B. paratyphosus (A), under the term Salmonella group. Most writers exclude B. paratyphosus (A), but the advantages of including these four organisms in a single group are considerable. This name is also more distinctive than the expressions "intermediate" or "paracolon" group which are sometimes used.

In addition to these bacilli a number of organisms obtained by various workers from many sources is often included in the Salmonella group. They have usually received a name indicative of the source from which they were derived, or of the morbid condition with which they were associated. Such are (1) B. psittacosis, isolated by Nocard during an outbreak of illness occurring among parrots in Paris; (2) B. typhi murium, which has been found in mice; (3) B. morbificans bovis, which was isolated by Basenow from a diseased cow; (4) B. icteroides of Sanarelli; (5) B. Danysz and many others.

From the observations of others and of myself, it appears that all these bacilli are identical with one or other of the four organisms described above. Thus B. psittacosis is apparently identical with B. suipestifer, and B. Danysz and B. morbificans bovis are indistinguishable from B. enteritidis (Gaertner). Some of the strains described as B. typhi murium are identical with B. suipestifer, others with B. enteritidis (Gaertner), others, again, are mixtures of these two bacilli.

Nothing is gained by retaining this somewhat confusing array of different names for the same organisms; and it is both simpler and more accurate to regard the Salmonella group as consisting of only four organisms, namely: (1) B. paratyphosus (A); (2) B. paratyphosus (B); (3) B. suipestifer (or as an alternative name B. aertrycke); and (4) B. enteritidis (Gaertner).

This scheme of classification has recently been tested by Bainbridge and O'Brien. A large number of strains of bacilli belonging to the Salmonella group was obtained from food, or from cases of paratyphoid fever or meat poisoning. All the strains were readily recognised as identical with one or other of the above members of the Salmonella group. No anomalous strains were met with, and the investigation entirely confirmed the foregoing classification. They also found that all the strains of B. suipestifer were derived either from meat or from cases of meat poisoning, whereas all the strains of B. paratyphosus (B) were obtained from cases clinically resembling enteric fever or from persistent carriers after such an illness.

This classification is not accepted by most German writers, who do not make use of either the absorption or the complement deviation method for this group, and therefore draw no distinction between B. suipestifer and B. paratyphosus (B), or between paratyphoid fever and meat poisoning.

These four bacilli are evidently extremely closely related to one another, and their differentiation depends upon the use of rather delicate methods and requires careful technique. The differences, however, are constant and persistent, and I have found that the strains of these bacilli kept in the laboratory and tested from time to time during the last four years have remained absolutely stable in their characters. We shall see also that these distinctions, slight though they are, correspond with wide differences in the distribution of these bacilli and in the nature of the illness to which they give rise. I believe, therefore, that they may be regarded as entirely distinct species.

Experiments on Transmutation.

Attempts have been made, however, to show that transmutation may occur in the animal body, and even *in vitro*. Thus, Schmitt injected B. suipestifer into calves, and after a few days recovered from their blood in some cases a bacillus which corresponded in its agglutination reactions to B. enteritidis (Gaertner). Two experiments yielded a positive and three a negative result. He concludes that these two organisms are not different species, but merely varieties which can be readily transformed from one to the other in the animal body. These experiments are open to the criticism that the Gaertner's bacillus obtained from the calves may have been present in them before the injection of B. suipestifer. This possibility was not excluded by Schmitt, althought Gaertner's bacillus undoubtedly occurs at times in calves.

I have repeated this experiment by feeding healthy guinea-pigs with B. enteritidis (Gaertner) and subsequently examining their fæces from time to time. It was found that the same guinea-pig might yield in the culture at one time B. suipestifer, and at another time Gaertner's bacillus, and another time both organisms. The explanation has been shown to be that B. suipestifer is a frequent inhabitant of the alimentary canal of healthy guinea-pigs, and that in these experiments it was a matter of chance which organism was isolated.

The evidence that transmutation of these organisms takes place in the animal body is, therefore, far from convincing, and the difficulties in showing that these organisms undergo modification there are great. The fallacies which beset the question of transmutation in the animal body are largely eliminated in experiments made in vitro, and Sobernheim

and Seligmann claim to have observed the gradual transformation of culture of Gaertner's bacillus into B. suipestifer in the laboratory. This observation, however, has not been confirmed by others, and the transformation of these organisms cannot be regarded as proved.

Nevertheless, it may be conjectured that the members of the Salmonella group have arisen by a slow process of evolution from a common ancestor; and the fact that these bacilli, as we know them now, are usually found in different species of animals suggests that possibly they have become modified by prolonged existence in animals of a given species.

DEFINITION OF PARATYPHOID FEVER AND MEAT POISONING.

We may now proceed to define paratyphoid fever and meat poisoning before considering in detail the clinical and epidemiological characters of these two diseases, and the evidence on which the definition is based.

Paratyphoid fever may be defined as a disease which clinically resembles, and is often indistinguishable from, enteric fever, and which is caused either by B. paratyphosus (A) or by B. paratyphosus (B); the latent period varies generally from 8 to 18 days, and the usual mode of infection is by human carrier cases.

Meat poisoning is a disease of which the characteristic symptom is acute gastro-enteritis of comparatively brief duration, and which is caused in a very considerable proportion of cases by either B. enteritidis (Gaertner) or B. suipestifer; the latent period is short, rarely exceeding 48 hours, and the usual source of infection is contaminated meat.

Other definitions of paratyphoid fever—namely, that held by German writers and that recently suggested by Firth—will be subsequently considered.

PARATYPHOID FEVER.

The cultivation of a paratyphoid bacillus from the blood of a patient "with all the clinical features of typhoid fever" by Gwyn in 1898 represents the first definite diagnosis of a case of paratyphoid fever, although he described it as a "paracolon bacillus." Schottmüller found in similar cases two species of paratyphoid bacilli which Brion and Kayser labelled (A) and (B). The symptoms of enteric fever may be caused, therefore, either by B. typhosus or by B. paratyphosus (A) or by B. paratyphosus (B).

During the last few years a considerable number of cases of paratyphoid fever caused by B. paratyphosus (B) have been recorded; and the important investigations of the Royal Army Medical Corps workers in India have made extensive additions to our knowledge of the paratyphoid (A) bacillus fever. For the sake of convenience these two infections will be dealt with separately, although, as we shall see, their clinical features and epidemiology are practically identical.

PARATYPHOID (A) FEVER.

Paratyphoid fever caused by B. paratyphosus (A) occurs in most parts of the world, although curiously enough no case has yet been recorded in this country. In Germany 8 cases in all have been described. In France two epidemics have been recorded, one of 19 cases by Netter, and one of 16 cases by Nicolle and Cathoire. In America Proescher and Roddy examined 262 patients whose symptoms were those of enteric fever, and found B. paratyphosus (A) in 8 per cent.; the diagnosis was made by blood cultures and was confirmed by agglutination tests.

Paratyphoid fever in Europe is much more often caused by B. paratyphosus (B) than by B. paratyphosus (A). But the cases mentioned above suffice to show that paratyphosus (A) infection is not so rare in Europe as is sometimes supposed. There is no doubt, however, that it occurs much more frequently in Asia, and particularly in India, than in Europe. In India, indeed, paratyphoid (B) infection is almost unknown, and according to Castellani this holds good also for Ceylon. Paratyphoid (A) fever was first recognised in India by the members of the Enteric Fever Commission in 1906–08; B. paratyphosus (A) was isolated from four patients. Since that time cases have been described by Morrison, Harvey, Wood, Grattan, and others.

As soon as attention was drawn to the matter it became clear that paratyphoid fever was far from uncommon in India. In 1910 39 cases were isolated, and it has been calculated by Grattan and Wood that probably a third of the cases returned in India as pyrexia of uncertain origin are in reality cases of paratyphoid fever due to infection by B. paratyphosus (A). Since 4386 cases of pyrexia of uncertain origin occurred among the British troops in India in 1909, paratyphoid fever is evidently widely prevalent. A chart drawn up by Grattan and Wood shows that most of the cases have occurred in the northern half of India, although the disease has been recognised as far south as Poona. It has also been met with in Ceylon, Sumatra, and South Africa.

Prevalence as Compared with Enteric Fever.

The actual prevalence of paratyphoid fever caused by B. paratyphosus (A) is probably most readily realised by comparing it with that of enteric fever. Not only is the incidence of the latter in most countries carefully recorded, but also the large majority of paratyphoid fever cases have been met with in the course of investigations of outbreaks of enteric fever. For instance, during the years 1901–07 505 cases clinically resembling enteric fever were bacteriologically examined by Kayser in Strasburg; 473 of these yielded B. typhosus, whereas B. paratyphosus (A) was isolated in 5 cases only (just over 1 per cent.). In the series of 262 cases examined by Proescher and Roddy, B. typhosus was isolated from 11 per cent. and B. paratyphosus (A) from 8 per cent.

During the year 1910 there were in the British army in India 306 cases of enteric fever and 44 cases of paratyphoid (A) fever, the latter forming nearly 15 per cent. of the total cases. According to writers in India, the real percentage of paratyphoid cases, as compared with enteric fever, would be even higher if all the paratyphoid (A) cases were distinguished. Incidentally it may be noted that prophylactic inoculation against enteric fever does not seem to confer any protection against an attack of paratyphoid fever. Forty of the 44 cases of paratyphoid fever just mentioned had been inoculated previously against enteric fever.

Seasonal Prevalence.

In America most of the cases seem to occur in September and October, and the curve of incidence as regards the time of year closely follows that of enteric fever. So far as can be gathered, paratyphoid and enteric fever also occur for the most part at the same time of year in India—namely, the hot dry months of April and May.

Bacteriology.

In almost all the cases here referred to the bacilli were identified by both cultural and agglutination tests. They appear to correspond in all respects with strains of the bacillus isolated in Europe. One strain, however, isolated in India, although identical in its cultural characters with B. paratyphosus (A), was not agglutinated at all by a paratyphoid (A) serum. Nor did the serum of a rabbit inoculated with this organism agglutinate B. paratyphosus (A). A similar organism has been found from time to time by Morgan in the excreta of healthy men and of pigs. It is not agglutinated by the serum of animals inoculated with Schottmüller's strain of B. paratyphosus (A) and may be described as B. pseudo-paratyphosus (A), since it is analogous to the pseudo-Gaertner organisms described by Savage. It is apparently a harmless saprophyte, and it is desirable not to confuse it with the true B. paratyphosus (A). The omission of this precaution has led to erroneous statements as to the distribution of the genuine organism in man and animals.

Apart from cases of clinical paratyphoid (A) fever, the bacillus has been met with once in acute gastro-enteritis, on two occasions from the gall-bladder during operation for gall-stones, and in one instance from an abdominal abscess which followed paratyphoid (A) fever. It does not occur in healthy men except after an attack of paratyphoid fever. Nor has it been found (with one exception) either in the lower animals or in food or water. The distribution of the bacillus is practically limited, therefore, to cases of paratyphoid (A) fever, or to those who have become carriers as a sequel of this disease; and there can be little or no doubt that it is the cause of the illness with which it is associated. It thus resembles B. typhosus or B. paratyphosus (B), not only in being essentially an inhabitant of the human rather than the animal intestine, but also in its predilection for the gall-bladder.

Clinical Features.

The course of a typical case of paratyphoid (A) fever closely resembles that of mild enteric fever. The incubation

period varies from 10 to 18 days, and is usually about 15 days. The onset of the illness is gradual, the patient complaining of severe frontal headache and pains in the back and limbs. Bronchitis and sore throat are not infrequent. The temperature rises in a step-like fashion, reaching its maximum by the fifth or seventh day; it falls gradually and becomes normal at the end of the second week. In severe cases the temperature may remain raised for three or four weeks. In contrast with mild enteric fever the pulse is rapid and is quite often as much as 110; the frequency of the pulse in paratyphoid fever does not necessarily indicate that the attack is a severe one. The abdomen is slightly distended, the spleen is enlarged, and constipation is the rule. The typical rash (rose spots) is often present and other forms of rash—e.g., purpuric or morbilliform—are occasionally seen.

Relapses are not infrequent and phlebitis, cholecystitis, and anæmia are not uncommon complications. Intestinal hæmorrhage and perforation have been observed, but are rare. Although practically every symptom and complication of enteric fever also occur in paratyphoid (A) fever the majority of the cases are of a mild character; sometimes the illness is so slight that it may be readily overlooked, and ambulant cases have been met with.

Post-mortem Appearances.

I have met with only one record of a post-mortem examination (Grattan and Wood). In this case the man died from perforation of the only ulcer which could be found at the necropsy; the Peyer's patches were not obviously enlarged, but the lower part of the ileum showed signs of inflammation. The spleen weighed 6 oz. and the wall of the gall-bladder was thickened and inflamed.

Mortality.

The death-rate is very low; Proescher and Roddy place it at less than 2 per cent. During the year 1910, 44 cases occurred in the British army in India, all of which recovered. This striking difference between the mortality of enteric and paratyphoid (A) fever is of considerable importance. In the first place, the recognition of a given case as paratyphoid fever at once enables a favourable prognosis to be made. Secondly, the fact that a large number of cases which have been formerly described as enteric fever are paratyphoid (A) fever must considerably modify our views as to the mortality of enteric fever. In the British Army during the year 1910 there occurred 306 cases of enteric fever, with 47 deaths, a mortality of 15·3 per cent. If we add to these the 44 cases of paratyphoid fever which *formerly* would have been recorded as enteric fever we arrive at a mortality of 13·4 per cent.

Diagnosis.

1. *Isolation of the bacillus.*—The only certain means of diagnosing paratyphoid (A) fever is the isolation of the bacillus from the blood or stools of the patient during life, or from the spleen or other organs after death. Paratyphoid (A) fever is a septicæmia, and blood cultures made during the first week of the illness give a positive result in the vast majority of instances.

2. *Serum reactions.*—The diagnosis of this disease in India by the serum reaction of the patient is complicated by the fact that most of them have been previously vaccinated against enteric fever. In such instances it has been found that, even when the cause of the illness is B. paratyphosus (A), the agglutination titre of the serum for B. typhosus rises considerably, and may be higher than that for B. paratyphosus (A). Even under the most favourable circumstances the patient's serum rarely gives a positive reaction for the latter organism in a higher dilution than 1–100. Sometimes the agglutination of B. typhosus is marked, whereas B. paratyphosus (A) is not agglutinated by a 1–10 dilution of the serum. In other cases of undoubted paratyphoid (A) fever the patient's serum agglutinates at one time only B. typhosus, at another only B. paratyphosus (A).

Harvey and Wood have shown that the use of the absorption method often gives valuable information as to the true cause of the illness. In cases of paratyphoid (A) fever in which the patient's serum agglutinated both the typhoid and the paratyphoid (A) bacillus they found that absorption with B. paratyphosus (A) removed all the agglutinins present, whereas absorption with B. typhosus removed only the co-agglutinins for that organism, leaving intact the specific agglutinin for B. paratyphosus (A). The absorption method is also of value in those instances in which the patient's serum agglutinates B. typhosus but not B. paratyphosus (A); absorption with B. paratyphosus (A) removes all the agglutinins from the serum.

The variable and comparatively feeble production of agglutinins in paratyphoid (A) fever has been noticed not only in India but also in Europe, and it seems to be characteristic of infections with B. paratyphosus (A).

The fact that the serum of a patient suffering from enteric fever may agglutinate not only B. typhosus but also B. paratyphosus (A) must be taken into consideration. Boycott examined 86 cases of enteric fever, and found that in 48 of these the patients' serum contained secondary agglutinins for B. paratyphosus (A). The secondary agglutinin was usually small in amount, and only in one patient was the agglutination titre identical for both B. typhosus and B. paratyphosus (A). Occasionally, however, the amount of secondary agglutinin may be considerable. Mixed infection with the typhoid and paratyphoid (A) bacilli is also possible, although it has not yet been observed.

It is clear that as a means of diagnosing paratyphoid (A) fever serological observations are beset by many sources of error and need very careful technique. They cannot be relied upon as a trustworthy routine method of diagnosis.

Epidemiology.

Our knowledge of the epidemiological characters of this disease is entirely due to the work of the Royal Army Medical Corps in India. The accumulation of evidence as to its spread in India has been materially assisted by two factors. In the first place, a large proportion of the patients admitted to hospital as suffering from enteric fever have been vaccinated against this disease, and the occurrence of symptoms of enteric fever in vaccinated individuals has naturally caused their blood and excreta to be examined with unusual care. Secondly, in some stations the medical officers have been able to make almost daily examinations of the excreta of these patients over a period of many weeks or even months.

For these reasons attention has been more readily called to cases of paratyphoid fever which might have escaped diagnosis if occurring in an unvaccinated population. It is probable, indeed, that the prevalence of paratyphoid fever in India has become so evident partly owing to the comparative infrequency of enteric fever in the British army. However this may be, the routine examination of convalescent cases of paratyphoid (A) fever has yielded extremely valuable information with regard to the existence of human carriers of B. paratyphosus (A).

Carrier Cases.

During 1910–11 at Naini Tal enteric depot 10 carriers were discovered out of 157 convalescent paratyphoid cases. Nine of these carriers were acute and ceased to excrete bacilli within three months of the termination of their illness. In the tenth case the excretion of the bacilli ceased at the end of five months. All these cases were fæcal carriers; no urinary carriers were discovered. In this respect paratyphoid fever seems at first sight to differ from enteric fever, in which about 2 per cent. of the total cases become *chronic* fæcal carriers.

It may be noted, however, that almost all the paratyphoid (A) cases described in India occurred in men and that cholecystitis or other evidence of infection of the gall-bladder was comparatively rare. It will be remembered that the large proportion of chronic carriers of B. typhosus are women, and that many of them are suffering from disease of the gall-bladder. It seems not improbable, therefore, that the infrequency of chronic paratyphoid (A) carriers in India results from the special circumstances under which it has been studied in that country, and is not necessarily a constant characteristic. There is, in fact, definite evidence of the existence of chronic carriers of B. paratyphosus (A).

Blumenthal has recorded the case of a woman who was operated on for gall-stones. B. paratyphosus (A) was obtained both from the gall-stones and from her stools, although the patient had not recently suffered from paratyphoid fever. The organism was agglutinated by the patient's serum in a dilution of 1–300. Another chronic carrier, also a woman, was met with by Aoki; in this case the patient became a carrier after an illness resembling mild enteric fever, and her serum also agglutinated the bacillus.

Dr. Ledingham also informs me that he has met with a chronic carrier (a man) who had had paratyphoid (A) fever 8–10 years previously.

There appears, indeed, to be no essential difference between enteric and paratyphoid (A) fever as regards the occurrence and character of carrier cases.

Infection Caused by Carriers.

The comparative mildness of most cases of paratyphoid (A) fever in India apparently causes the true nature of the illness to be overlooked from time to time. Moreover, ambulant cases are not unknown, two having been described by Grattan and Wood. Cases of this kind are obviously liable, whether they become carriers or not, to serve as centres for the spread of the disease.

There is also strong presumptive evidence that patients who have recovered from paratyphoid fever, but are acute carriers, can give rise to outbreaks of this disease. For example, Harvey and Grattan have described a small outbreak (8 cases) of paratyphoid (A) fever in which the evidence suggested that the illness was caused by a cook who had recently suffered from this disease complicated by cholecystitis. The serum of the cook was tested and gave a positive reaction to B. paratyphosus (A), and shortly after he was found to be passing this bacillus in large numbers in his stools. The cases of paratyphoid fever began to occur a fortnight after the cook had been discharged from the hospital, and the last case was admitted 12 days after he was isolated for the second time. All the cases took place, therefore, during a period in which infection by this cook was possible, and only during that period. These facts point to this man being the actual source of the infection, the more so as other sources had been excluded as far as possible.

It is not known whether the more frequent source of the spread of the disease is infection by acute carriers or by unrecognised cases. Grattan and Wood, however, consider the acute convalescent carrier to be the chief cause of the spread of the disease in India. So far as can be gathered, there is nothing to show that water-supplies or flies play any part in the spread of infection.

A Clinical Lecture
ON
DERANGEMENTS OF THE KNEE FOLLOWING STRAINS AND BLOWS.

BY ARTHUR E. BARKER, F.R.C.S.,

SURGEON TO UNIVERSITY COLLEGE HOSPITAL AND CONSULTING SURGEON TO THE QUEEN ALEXANDRA MILITARY HOSPITAL, MILLBANK, S.W.

GENTLEMEN,—It is impossible to say whether strains and consequent derangements of function of the knee-joint are more frequent now than some years ago, but I can vouch for the fact that one is consulted about these injuries more often nowadays than formerly, both in and out of hospital. Also that the varieties of lesions which one sees appear to be greater for some reason. This may be an actual fact, but is more probably due to the acquisition of a greater power of discrimination between the various mechanical lesions met with.

I want to-day to discuss with you some of these strains and blows and their consequences, in the light of many cases about which I have been consulted here in the hospital and elsewhere.

PARTIAL SEPARATION OF SEMILUNAR CARTILAGE.

To begin with, I may mention a case which I saw a few days ago with a fairly common history.

CASE 1.—The patient was an ardent football player, and last autumn, during a game, an opponent flung himself violently against the outer side of his left knee while the leg was extended and the foot was resting firmly on the ground. This, of course, forced the knee inwards and put a very severe strain on the internal lateral ligament. The pain was severe, but was described as seated over the outer side of the joint, and not the inner, where the chief strain would mechanically fall. It may have been due to the actual blow upon the outer side. However, this pain passed off, and—as I understood the patient—without any effusion into the knee. Then a month or so later in kicking off with the same leg he felt violent pain in the knee, this time on the inner side, at about the lower insertion of the internal lateral ligament. The accident was followed by great effusion, distending the synovial pouches on either side. This subsided in about four days, and when I was consulted three weeks later there was no trace of it. The joint appeared normal in every way except for a little tenderness over the internal lateral ligament. The only complaint made now by the patient was that if he kicked out with the limb he felt violent pain on the inner side of the knee. When walking he felt no trouble of any kind, and could flex and extend his knee without difficulty. There was never, he said, any catch or "locking" of the bones.

The interpretation of this condition is, to my mind, not quite easy. One's first thought is that it might be explained by the strain alone of the two lateral ligaments, and a certain amount of tenderness when any unusual tension was exerted on them, as in energetic kicking. But that view is not quite satisfactory, for it does not fit in with the absence of effusion on the first lateral injury, and the rapid filling of the joint and pain on the inner side with the second, the strain this time being applied in the movement of forced extension.

What appears more probable is that the first accident stretched the internal lateral ligament and capsule on the inner side of the knee. The internal semilunar cartilage being held in its place by its attachment to the capsule would be rendered more mobile by this loosening of the capsule. Remember that during flexion of the knee the internal semilunar cartilage moves normally backwards and towards the centre of this joint, following the convexity of the femur, the expansion of the quadriceps at the same time being lax. When extension begins the tendinous expansions of the extensor muscles are rendered tense over the front and sides of the joint, and with them the capsule underlying them. This should draw out the semilunar cartilage into its normal position as the femur slides upon the tibia. But if, as after stretching or partial tearing of the internal lateral ligament and the adjacent capsule, the semilunar cartilage has receded further inwards than normal, it can on extension be jammed between the condyle and the tibia, and held thus while the capsule and muscular expansion are drawn tightly outwards. The result of this is that the two bones are kept apart by the meniscus wedged between them, instead of following their movements, and as the leverage is great the internal lateral ligament is stretched and great pain is felt.

Besides this, the capsule, being drawn away from the fixed semilunar cartilage, is often more or less torn off its outer periphery, adding to the pain, as it is highly furnished with nerves. Neither the encrusting cartilage of the bones nor the meniscus is sensitive. The pain is always due to the strain or tearing of the ligaments and capsule. The rent between the outer border of the meniscus and the capsule may be very slight when the catch occurs for the first time, and I have seen it not more than half an inch long. But this is quite enough to increase the mobility of the cartilage and to admit of its receding further than before into the joint during each subsequent flexion, especially if combined with eversion of the tibia.

Such a strain as I suppose to have occurred in this case increases the liability to subsequent jamming of the meniscus between the bones, and, consequently, to extension of the rent begun by the preceding catch. In this way, by successive jamming of the free margin of the semilunar cartilage between the two bones, the capsule may ultimately be completely torn away from the thick border of the meniscus, which at last may be only attached to the tibia by its cornua, and otherwise float free in the joint as one has often seen. Such a separation rarely takes place as the result of one accident. It is the sequel to many separate catches and drags. Each of these strains produces more or less traumatic synovitis, which, as a rule, however, soon subsides. But in many cases each attack leaves behind it some hyperæmia and weakness of the joint, and as the problem of relief is purely a mechanical one the loose cartilage should be removed before the joint becomes permanently overstrained and damaged.

In the case above related I say that I believe the lesion to be a partial separation of the semilunar cartilage due to stretching of the internal lateral ligament and capsule. But one cannot be certain as yet and I have advised support of

the knee by an elastic bandage and easy exercise. If the pain persists on sudden flexion of the knee I shall advise an exploration of the joint. For it cannot be denied that as a rule a displaced meniscus is accompanied by some arrest of movement, either in extension or more rarely in flexion, and there is none in this case. And it may be that the pain on sudden extension in this case felt on kicking out may be due to the first stretching of the lateral ligaments, combined with some consequent synovitis and hypersensitiveness of the swollen membrane.

ENLARGED SYNOVIAL MEMBRANE.

That a swollen synovial membrane, after strains and blows on the knee, may give rise to symptoms closely simulating a displacement of the semilunar cartilage, is clear from many cases which we have seen and operated on. In these cases we have a history of injury such as a violent wrench of the knee, almost invariably with the foot and tibia everted. After this there is effusion, and when this has passed off a sense of weakness, which in the position of partial flexion often "lets the patient down." There may even be a slight catch or locking of the joint for a moment, but never in my experience a complete arrest of movement, such as we often get in typical dislocation of the meniscus.

Still there is evidence that the obstacle to the easy movements of the articulation is a mechanical one, and when on this ground we have felt justified in exploring the joint in some cases redundant fringes of hypertrophied synovial membrane have been found, and on their removal all symptoms have been relieved. They are usually most redundant behind the patella, and can be drawn into our usual incision and cut off with scissors. They consist of fringes of synovial tissue, thickened and swollen by inflammatory exudation.

All these cases of chronically enlarged synovial fringes do not require operation, however. Under treatment of rest, with blistering or the use of Bier's bandage, they may be reduced in size and give no more trouble. It is only when this treatment fails that they require excision. Another point about them is that they are often met with in rheumatic people, and the doubt may arise as to whether the pain is not all rheumatic.

RHEUMATOID ARTHRITIS IN THE KNEE.

This point opens up an interesting question. Many patients with more or less obvious rheumatoid arthritis of the knee-joint often develop after a strain or a blow, symptoms which suggest a displacement of a semilunar cartilage. There are pain and stiffness sometimes amounting almost to "locking" in one position. Here it is necessary to consider whether the movements are affected by irregularity of the joint surfaces due to the osteo-arthritis, or actually to a loosening or displacement of the meniscus. Both may be present. For it is well known that in rheumatoid arthritis the semilunar cartilages become less elastic and their surfaces less polished, as does also the cartilage covering the condyles, so that two factors are present likely to lead to their being caught between the bones when having receded between them during flexion they ought to return during extension.

This is a very difficult matter to decide on, and sometimes quite impossible without operation. For my own part I have long hesitated to operate in these doubtful cases. But in several, with some hesitation, I have opened the joint and found *both* conditions present. In these I have removed the meniscus, and afterwards cut away the osteo-arthritic excrescences at the borders of the bones, with complete relief. Of one of these I have heard since that he was climbing the mountains in Switzerland, and the other patient has recently consulted me about another ailment, the knee I had operated on giving him no further trouble. In other cases the treatment has been that for the rheumatoid condition alone, and has been as successful as could be expected.

TYPICAL DISPLACEMENT OF MENISCUS.

The history and symptoms of a typical displacement of the internal meniscus are so clear that they can hardly be mistaken. It is very rare for the external to be dislocated.

Please remember that the attitude of the knee, in which jamming of the thin edge of the cartilage between the bones is most likely to take place, is one of flexion, in-bending of the joint, and *eversion* of the tibia. This normally brings the cartilage well in between the condyles and the tibia as far as its peripheral attachments will allow it to go. The force applied will nearly always be such as to have produced this attitude if we inquire into it closely. It is sometimes a fall, sometimes a wrench at football, or a long jump, and often appears to develop slowly after a series of trifling jars, such as knocking the foot against the treads of a staircase in ascending or flinging the leg over a bicycle.

Symptoms.

But, however caused, the symptoms are the same. There is severe pain usually over the inner side of the knee, and a "locking" when the patient tries to extend the limb. This locking may be very transient or last for hours or days, and may disappear during sleep or after the limb has been well flexed and then inverted before being again extended. When it has disappeared the movements of the joint are perfect and painless unless there is much effusion, which is common, but does not last long. It may be weeks or months before another catch occurs, and in the meantime the patient may be unconscious of anything being amiss with the joint until after extension with the foot everted it may suddenly and unexpectedly get caught again with the same pain. The intervals between these attacks usually become shorter and shorter as the semilunar cartilage becomes looser. In a few cases the meniscus when quite detached, except at its cornua, seems to shrivel up into the intercondyloid notch and gives no further trouble at all, but such cases are rare.

Position and Amount of Detachment.

The detachment commences most frequently, in my experience, as seen in operations, on the anterior and outer aspect of the periphery of the meniscus, and the rent extends from this point forwards and backwards. But occasionally it begins behind the internal lateral ligament and extends only backwards, rarely until the posterior cornu is separated from the bone.

These are the cases in which it is sometimes difficult to detect the lesion when the joint has been opened, for the rent is hidden. But the separation is rendered clear by putting a small steel hook into the meniscus far back during extreme flexion and eversion of the leg and pulling it forward. If it is detached it will slip over the convexity of the condyle more or less, or actually into the anterior part of the joint, and be seen to be loose. In this condition it may often be possible to demonstrate the particular movements of the joint which dislocate it. For instance, it may be pushed back into its normal position and the knee extended once more. Then if the joint be slowly flexed with the leg everted, while the wound is held open, it may be seen at one particular moment that the cartilage slips over the convexity of the condyle with a sudden jerk and even a sound which are very characteristic.

It is remarkable what a small amount of separation of the external attachment of the meniscus is enough to produce definite symptoms of catching and pain in the joint. Several times I have seen on operating, where the evidence of displacement was clear, a rent of not more than half an inch long between the anterior border of the semilunar cartilage and the capsule stained by the remains of blood-clot and still showing the ragged, torn surface.

As a rule, however, where several "attacks" have taken place this ragged, torn surface is seen to have healed and become rounded and polished. But it is clear that it requires very little separation of the meniscus from its peripheral anchorage to enable its free margin to get caught between the bones, whether the rent be in the posterior or the anterior part of the periphery of the meniscus. This is hardly to be wondered at when the extremely delicate mechanism of the joint is considered.

Mechanism of Knee-joint.

The crude conception of the knee as a simple hinge is far from covering the whole mechanism. The play of each condyle on the tibia and semilunar cartilages has in some respects more of the elements of a ball-and-socket movement than is commonly supposed. And if there is any loosening of the various guiding ligaments in its movements, and particularly if there is any striation or loss of polish on the surfaces as the gliding takes place, derangements are not to be wondered at.

The mere play of the capsule over the "lipped" borders of rheumatic bones may also give rise to unusual dragging sensations in the movements of the joints, just as one has often seen one of the inner hamstring tendons caught either in

front of or behind a small exostosis which has appeared and grown larger and larger on the inner side of the head of the tibia. Moreover, an osteo-arthritic nodule on the border of the encrusting cartilage of either femur or tibia may interfere with the free play of the internal lateral ligament during flexion and extension and give rise to much pain and even a suspicion of derangement of the semilunar cartilage when a more or less sudden catch occurs.

It will remain for the future to determine whether in cases where we have reason to suppose that the osteo-arthritic nodules are in the way of either the capsule or lateral ligament it would not be proper to remove them by operation. In two or three cases in which after removing a displaced meniscus I have chiseled or pared them off, I thought the conditions were improved very much.

CHIPS OF ARTICULAR CARTILAGE FREE IN THE JOINT.

In addition to the effects of blows and strains just mentioned, it must not be forgotten that pieces of articular cartilage may be chipped off by direct impact upon the lateral aspect of the knee. I believe that it is usually the femur which is affected. So far I have only seen one quite unmistakeable instance of this in my own work.

CASE 2.—The patient was a girl who was struck sharply on the inner side of the knee, and who developed signs of "locking" after effusion had gone down. Nothing could be felt at first, but later a small solid mass which could be moved by the fingers could be felt at the inner border of the joint under the capsule. When manipulated it disappeared. I opened the joint and found a flattened scale of bone covered with encrusting cartilage, and also the depression on the border of the cartilage of the femur, from which it obviously had been broken.

The specimen is on the table before you. It is, as you see, about the size of a sixpenny-bit and four times as thick. I cannot imagine such a chip being broken off the tibia and getting free into the joint, for it would lie under the semilunar cartilage. Moreover, the configuration of the upper surface of the tibia is such that mechanically it would be difficult. Again, the femur, being much broader than the tibia, would receive most of the blows in that region before the tibia could be touched.

RUPTURE OF LATERAL LIGAMENTS.

Very violent wrenches to the knee-joint may produce some most interesting lesions short of the classical fractures of femur, tibia, and patella. Thus extreme extension may stretch or actually rupture the lateral ligaments.

The symptoms are undue lateral mobility when the limb is fully extended, with great unsteadiness on walking, if not complete inability to use the limb when the pain and effusion into the joint have subsided. It is well known that in full extension there ought to be no trace of lateral movement in the knee. But with rupture of the lateral ligaments this lateral rigidity is gone, for the external crucial ligament cannot restrain the bones when the supports at the side are removed. But besides this, a certain amount of rotation is present of tibia and femur, which becomes more free than normal in slight flexion.

This is a very serious injury, and it is questionable whether any operative treatment is likely to be of use. Immobilisation of the limb in slight flexion is probably the best we can do, care being taken that the fixation is not too prolonged.

RUPTURE OF CRUCIAL AND PROBABLY OF LATERAL LIGAMENTS.

Another result of violent strain on the knee was once described to me so clearly by a patient who came home for advice from Africa as to remove any doubt as to its nature which I might otherwise have had.

CASE 3.—The patient was a mining engineer on the Rand, and was overwhelmed, when down a shaft, by falling earth and rock. According to his description, this fell upon his bent shoulders and thrust him forwards while his legs were pinned firmly. When he was rescued one of his legs was much distorted. The tibia was, according to him, dislocated backwards into the ham, and the femur projected far beyond it forwards. The whole lower leg became black and threatened gangrene. Amputation was urged upon the patient as the only means of saving life, but was absolutely declined at no matter what cost. The surgeons on the spot recognised a total dislocation of the tibia backwards, and were hopeless of saving the limb or life except by amputation. On the patient's refusal, a last attempt at reduction was made and was successful.

To me the most remarkable fact about this case was this, that when the patient consulted me some months later he could walk well, and the movements of the joint were free and fairly firm. His object in seeking advice was really to know whether he would be wise to undertake the same work again. I advised him to go to his home, in the South-West of England, for a few months, and to have sea-bathing, when I should be better able to judge. At the end of that time he was quite well, and quite fit to return to his position in the mines. This case impressed me much. From his description, and from what the surgeons who saw him after the accident told him, I think there can be no doubt that there was a complete dislocation of the tibia backwards, and pressure on the popliteal vessels. It is hard to suppose such a displacement without rupture of the crucial ligaments, and probably of the lateral as well. And yet the result of reduction was complete restoration of the movements of the articulation, and ultimately of a firm limb.

The possibility of union of these ligaments when the limb is brought into good position seemed to me to be proved by this result. Another case, however, suggested a doubt on this point. Curiously enough this patient, too, came for advice from the Rand mines in Africa and had received his injury much in the same way. I recorded the case at the time in full[1] and now give you a digest of the report.

FRACTURE OF TIBIAL SPINE OR DEGENERATIVE CHANGES?

CASE 4.—The patient was aged 30 and perfectly healthy. When in the mine a large, flat stone fell from a height of about 20 feet upon his back as he stooped, and rendered him unconscious. When he recovered his left knee was much swollen and very painful. Ice was applied, but the swelling did not subside for 12 days. At the end of that time the knee was flexed by a doctor forcibly, producing a snap in the joint and a feeling of faintness for some hours. He was then treated by rest for five weeks in a plaster-of-Paris splint. On its removal he tried to walk for a fortnight and had again a plaster case applied for five weeks. After that only a leather splint was worn.

Condition on examination.—On entering my room the patient walked with a stiff leg, wearing the splint. On its removal the first thing noticed was a lateral yielding of the knee and a tendency when weight was thrown upon it to assume a position of genu valgum. It was evident that the patient walked with great insecurity and a distinct snap could be heard as the knee bent inwards and forwards. There was some pain, but the chief complaint was of the total absence of any sense of security in walking on the leg and its tendency to give way suddenly inwards with the snap described, which was quite audible at the end of a long room.

On examining the limb by passive motion there was a large amount of lateral movement of the tibia on the femur in the sense of lateral flexion. Rotation, also, of the tibia on the femur was much freer than normal. Slight over-extension of the knee was also possible. Lateral displacement of the tibia on the femur was doubtful, and if present at all was only so to a very small extent. On the other hand, the tibia could be suddenly slipped back either by passive movement or the patient could throw it back by muscular action himself. When thus displaced he could not bring it forward again by the action of the muscles, but with his hand in the ham he could easily bring it into position in a moment, but not beyond the natural limits.

Traction produced no trace of separation between the surfaces of femur and tibia. There was some thickening of the synovial membrane and slight crackling on movement. It was thought, also, that there was some lipping of the cartilage at the borders of the tibia on the affected (left) side, not on the right. There were no symptoms of locomotor ataxy and no "locking" of the knee in any position.

On first seeing the patient I was inclined to think that the internal lateral ligament was stretched or torn, and that this would account for the inbending of the knee. But when the tibia was seen to slip back on the femur, the possibility of rupture of one or both of the crucial ligaments, or tearing off of the spine of the tibia at once suggested itself.

The fact that traction on the tibia produced no separation of the bones appeared to negative rupture of the lateral

[1] Clinical Society's Transactions, vol. xxix., p. 11.

ligaments, and it was difficult to account for the very remarkable slipping back of the tibia on the femur except by supposing that the control of the crucials had been lost either by rupture or by the spine of the tibia having been torn away with them. The increased power of rotation of the tibia on its long axis appeared also to favour the view that the lesion was in or about the crucial ligaments. The description of the accident, in which the knee was probably forcibly over-flexed, lent support to this view.

As to treatment of this case it was quite clear that immobilisation of the joint for just one year had been productive of no benefit, and further rest offered but little prospect of improvement. On the other hand, if the joint were opened and a lesion either of the crucial ligaments or of the spine of the tibia were found, it was problematical that any fixation of the ruptured tissues could be brought about. It seemed, however, possible that perhaps though I might not be able to suture the ligaments or pin down the spine of the tibia, after so long a period, still the opening of the joint and the mechanical irritation might provoke enough plastic exudation in the ligaments and capsule as to thicken them and perhaps lead to their shrinking somewhat and so giving more support to the joint. Should any greater stiffness result from faulty asepsis the limb would be more useful than in its present flail-like condition. After this was explained to the patient he was eager for operation.

Operation.—I performed it as follows. A transverse cut was made across the middle of the patella and it was sawn across. The capsule was divided in the same line as far as the lateral ligaments, which were left intact.

The knee was then flexed, and it was seen that there was very little osteo-arthritic "lipping" of the femur. The synovial membrane was everywhere hyperæmic and swollen, and its fringes were hypertrophied. The cartilage of the femur was striated, and over the outer condyle on its lower surface there was an area of erosion of the cartilage which was ragged, though the bone was not exposed. The anterior or external crucial ligament was intact. To obtain a more complete view of the joint a vertical cut was made downwards on each side from the ends of the transverse incision for an inch or two, and the resulting flap was turned down with the lower half of the patella.

The semilunar cartilages were now seen to be in their normal position. Round the outer side of the spine of the tibia there was an irregularity of the articular cartilage between the ends of the outer semilunar cartilage. From this a groove passed round the base of the spine of the tibia. This groove was large enough to take the end of a dissecting forceps or blunt periosteal elevator. When these were pressed into the groove they did not touch bone but rather soft tissue. The groove had all the appearance of having resulted from a horizontal fracture of the spine of the tibia with imperfect co-aptation of the broken surfaces.

With a blunt elevator I made a cautious attempt to move the fragment, and thought at one moment that it was not fixed. But this was uncertain. At all events, it seemed improbable that any good would result from pegging it, even if it were loose. One had to recognise that the derangements present could be produced by changes of measurement of only a millimetre or two. Nothing further was done except to wire the patella and stitch up the capsule first and then the skin. There was no drainage.

The wound healed perfectly under one dressing, and the limb was kept upon a splint for some weeks. The patient went on a visit to his friends five weeks after operation. I next saw him at my house three months later. He walked into the room with a good deal of stiffness, but stated that the limb was far more useful to him than before the operation, and that he was soon going back to his work in Africa. On manual examination I found the patella moveable and a certain amount of flexion possible. There were still some fulness about the knee and a little tenderness. The patient was well content with the result, which gave him a much firmer joint. He had not yet attempted to flex the knee actively, and I cautioned him against doing so for a long time to come, although I was able to bend it by passive movement. He promised to abstain from over-exertion.

In this case the alternative diagnoses considered before operation were either rupture of the external crucial ligament or tearing off of that part of the tibia into which the latter is inserted. The operation showed a groove round the base of the tibial spine, which may have represented the result of this fracture, but may have been due to degenerative changes in the cartilage, the result of rheumatoid disease. It also showed, I thought, that no efficient pegging-down of the fragment could be done after so long a lapse of time, though I believe this operation has since been performed in some fresh cases of the lesion.

A case was also shown at the Clinical Society by Mr. Stanley Boyd about the same time as this one in which the diagnosis was rupture of the external crucial ligament. The tibia in his case could be thrown both in front of and behind its normal axis. In my case it could only be jerked behind it, and when brought forward only came into its normal position.

I saw my case for the last time more than a year after operation. He walked well, and none of the abnormal movements observed were now present. Flexion was still somewhat limited, and I urged the patient still to abstain from forcing it. He was about to return to Africa, and was well contented with the result of the operation.

Besides the results of blows and strains of the knee-joint given above, you must remember that a blow may knock off a *rheumatic nodule*, which will then give all the symptoms of a loose body in the joint requiring removal by operation.

EFFUSION OF BLOOD.

Another cause of troublesome effects due to knocks and strains is the blood effusion which often follows them. This may be either into the cavity of the joint or into the tissues outside the synovial membrane.

From the first several different troubles may arise; the blood may clot and shrink into fibrinous masses and become rolled into pellets, playing henceforth the rôle of loose bodies and giving rise to the same symptoms until they are removed by operation. Doubtless, when the amount of blood is small the clots are broken up and absorbed in many cases. But these fibrinous masses are found when the blood is not absorbed.

Again, a large effusion may take place, remain unabsorbed, and cause irritation of the surfaces to an extent sufficient to produce plastic exudation. If this become organised the result is more or less fibrous ankylosis of the joint. This is clearly seen in a well-known preparation made by Volckmann. It was a case of simple transverse fracture of the patella treated on splints without any operation. Complete stiffness of the joint resulted, and the specimen was subsequently obtained. A frontal section through the joint shows an intimate union of the femur and tibia by firm fibrous tissue.

The reason why blood effused into one joint will produce distinct irritation of its surfaces and into another very little or none is not clear, and the various theories held in regard to the point would carry us too far to-day. But the fact remains. The removal of this blood is always indicated if it is seen to distend the joint, and this may be done with an aspirator, or in rare cases by an incision where the clots cannot be drawn off through the aspirator.

When blood is effused as the consequence of blow or strain into the tissue of and around the synovial sac, but not actually into the joint, it may also give rise to thickenings and rigidity of the membrane which cause a good deal of stiffness in movement.

Such patients are inclined to avoid all flexion and extension, or to keep the part fixed more or less in flexion. This is a serious matter if it be allowed to persist too long, especially in neurotic patients. There is considerable danger that the free play of the joint may be damaged unless passive movement and massage be begun fairly early and continued regularly.

These are the cases in which such remarkable results are obtained by forcible flexion and extension under an anæsthetic after all acute signs have passed off. They often bring much credit to the so-called "bone-setters," who announce that the joint "is out" and promise to put it in. What they really achieve is a breaking down of adhesions and restoration of movement. But you can do the same and ought to do so when you have sufficiently studied these conditions and are sure that you are not dealing with a latent tuberculous process which would be injured by forcible movements as I have seen after manipulation by a bone-setter.

HYSTERICAL AFFECTIONS OF THE KNEE.

It would lead me too far to-day to speak to you at any length of so-called hysterical affections of the knee which so often follow injury by strain or blow and which make up a very considerable proportion of the cases about which you are consulted. But you must always bear in mind that such cases are common and be on your guard.

I will mention one very remarkable case sent to me from a distance in July, 1910, to illustrate the need of great care in dealing with them and to what extent we may be deceived by them.

CASE 5.—The patient was an unmarried, healthy-looking woman, aged 27. When ten years old she had had her right foot accidentally trodden on and crushed, and it was some years before the hurt was healed. Since then she said she was unable to walk for 17 years—i.e., up to the date of admission. She underwent several operations, and was at last given up as hopeless. Some scars about the popliteal space suggest tenotomies.

Condition on examination.—The foot was pointed, the knee flexed to a right angle, and the thigh and hip were fixed in strong flexion and adduction. Nothing in the way of traction could alter the position of the limb either at the hip or knee, and the doctor who sent the patient to me referred to the condition as one of ankylosis of many years' standing—a view which, I believe, was endorsed by those who saw her first at hospital.

The history of not having walked for 17 years seemed to support the view, as did the facts that traction on the hip only produced lordosis, and traction on the knee caused no change in the attitude of the joint of right-angled flexion. It struck me, however, after one or two examinations that when one tried to extend the knee the hamstring muscles undoubtedly acted strongly, while an attempt at flexion was followed by a hardening of the extensors of the knee. As the joint was not tender there was no reason for this, and the patient's expression and whole demeanour suggested a highly neurotic person.

Examining further, I was convinced that there was no organic disease in hip or knee, and never had been; that the patient had been simply contracting both joints to avoid walking for reasons which appeared sufficient to a so-called hysterical woman. How she could have kept up this deception or self-deception for 17 years and undergone several operations on the limb is one of those mysteries about such cases which have yet to be explained.

Straightening of the limb under spinal anæsthesia.—The remedy appeared obvious: to give an anæsthetic and straighten the limb. But as I wanted the patient to see for herself that all the motions of hip and knee were perfect, and not only that, but to realise that all present in the operating theatre could vouch for her deception, I gave her spinal analgesia instead of a general anæsthetic. When sensation and motion were gone I took away the screen, and while she looked on carried both joints easily through all their normal movements, to her utter confusion. And not only this, but took hold of the foot which she had always complained of being exquisitely painful and stiff and forced it about in various directions, while she looked on in amazement and apparent chagrin. The limb was then kept extended on a splint, and the foot, which was, of course, atrophied by long years of disuse following the suppurative condition, had to be rubbed and gradually strengthened before it could be well used.

At the end of a fortnight she was walking about the ward with some stiffness, and the sole of the foot was not yet flat on the ground. But this was not to be wondered at considering the atrophic changes that could take place in all the structures of the part during 17 years. She got stronger and stronger every day and left the hospital just five weeks after the two "ankylosed" joints (!) had been proved to be quite sound, but still limping a little on the atrophied foot, as was to be expected.

The moral effect of seeing the three joints—hip, knee, and ankle—which she had been holding rigid for 17 years flexed and extended, and as regards the ankle, rather forcibly dealt with, was very great, and as she was witness to it herself there was no escape. A general anæsthetic would almost certainly have left her unconvinced. The publicity of our demonstration while she herself looked on brought conviction without a possibility of doubt.

HYPERSENSITIVENESS:

THE PARALLELISM IN THE PHENOMENA OF HYPERSENSITIVENESS AND CERTAIN CLINICAL MANIFESTATIONS OF OBSCURE NATURE.[1]

BY H. BATTY SHAW, M.D. LOND., F.R.C.P. LOND.,

PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; LECTURER IN THERAPEUTICS, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL; AND ASSISTANT PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

TWO or three years ago I overheard your secretary put a question to a colleague of mine which interested me very much, and for the reason that the inquiry was one which for years had required a solution, and just at that date there was little known which could in any way provide a solution. Dr. C. H. Hall raised the question, "Why it was that a healthy woman recently confined suddenly became comatose, and as quickly recovered completely?" I need not give you reasons why this unanswered question should have remained in my mind to the present moment, but the incident recurred to me when the same interrogator asked me if I would address you on the present occasion. It seems to me that a good reason why a teacher of medicine should undertake to address a number of practitioners like yourselves may well be that there is the necessity to place before you new facts and theories which since your own student days have come to the front to explain those hiatuses in medical knowledge which every medical man has to face when he settles down to the calls of general practice. The episode already referred to is a case in point.

Before attempting to give an answer to the problem raised, and other problems of kindred obscurity and importance, certain spade-work must be carried out by an attempt on my part to put before you certain new conceptions. Those conceptions have been attained to by the carrying out of animal experiments.

What is Hypersensitiveness?

The term "hypersensitiveness" is chosen with the distinct intention of endeavouring to avoid too technical language. It expresses in English a condition in which an animal is made more sensitive, rather than less sensitive, to the effects of certain poisons. Though the effects of a first injection may be *nil* or very small, those of a second may be severe, and always are characteristic.

It is interesting to note how the phenomena of hypersensitiveness came under observation. When this address is finished if any of you would recall the earlier experiments from which so much that is of importance to you, as I hope to show, has had its birth, I think you will admit, if ever you hesitated, that it is essential for advance in medicine that as a nation we must make provision for more research even though many of the objects of research appear to have little practical bearing.

It will provoke a smile when I tell you that the whole of this address has as its inspiration some of the countless investigations which have followed a simple observation made by Richet and Portier nine years ago, that if a preparation made by powdering up the tentacles of a sea anenome is injected on two occasions into a dog the second injection is followed by a group of symptoms which are familiar to every medical man—dyspnœa, vomiting, blood-stained evacuations, collapse, and death. The condition of the animal which rendered possible the occurrence of such symptoms was spoken of by Richet and Portier as anaphylaxis; to-night we use the term hypersensitiveness instead, which is more homely and a good deal in use amongst English and American writers. In fairness to other workers, it must be at once stated that some of the observations made by these two workers had been anticipated by v. Majendie, Flexner, v. Behring, Knorr, Kitashima, and others, but to Richet and Portier is due the crystallisation of the theory of hypersensitiveness.

The Expansion of Richet and Portier's Observations.

At first sight nothing could appear more alien to a consideration and explanation of the symptomatology of disease in man than this brief description of Richet and Portier's

[1] A paper read before the Watford Medical Society on Nov. 17th, 1911.

experiments. In the first place, the hypersensitiveness developed in the dog was produced by the introduction of derivatives of quite a different form of life; secondly, the route of introduction was one which can hardly occur in human pathology except as a result of trauma—a factor which has a somewhat limited application in medical disorders. Richet introduced the foreign substance by a route other than the alimentary canal.

These two points have, however, attracted the attention of Richet and Portier and numerous other workers, and the net result to-day is that it may be said that symptoms of hypersensitiveness may be produced whenever certain proteins derived from the vegetable kingdom are introduced into the body of an animal; or when proteins derived from one animal are introduced into another animal of different species. It will be subsequently seen that the field has been enlarged, and in a most important way so far as human pathology is concerned, for the organs of an animal have been shown to provoke the phenomena of hypersensitiveness when injected into the same animal. The results are more likely to follow if the protein is introduced by a route other than the intestinal one—e.g., through the veins, into the cellular tissues, or into serous cavities such as the peritoneum or upon mucous surfaces such as those of the nose and eye, or even into the heart.

To attempt to put before you the stages of those experimental inquiries would be impossible in this address; already one writer is able to give the number of papers bearing on the subject as 422. No doubt, however, there are many amongst you who will have noted that already there is some reason to feel that Richet and Portier's experiment, after all, has something to do with the explanation of some of the phenomena met with in practice in view of the expansion of their ideas and observations. Are you not already familiar with the various manifestations which occur after the use of anti-diphtheritic serum?—the joint pains, the fever, the rashes, and general disturbances which occur some 11 or 12 days after the injection. It is true that these phenomena occur after but *one* injection of serum in only a small proportion of the cases; but when it is remembered that similar and more intense symptoms may occur, and more frequently, after a second injection of the serum, then you will realise still more readily that the subject of the hypersensitiveness is of importance to you.

The Symptomatology of Hypersensitiveness.

The first purpose of this address is to put before you the various symptoms produced experimentally in animals when hypersensitiveness is induced; also to detail those symptoms which investigations have shown to occur when hypersensitiveness is induced in man as a result of the neo-therapy by means of vaccines, sera, &c., and then to ask you to recall certain symptoms present in familiar maladies, the nature of which is a perfect enigma even in these days of investigation, and to see whether it is not possible for us by a comparison of the known with the unknown to reasonably speculate as to the true nature of the latter.

"*Hypersensitive*" *Symptoms: (a) In Dogs.*

The animal will show a curious exaltation: it will become restless and tug at its chain within 30 seconds of the second injection of horse or ox serum; there will be prompt efforts at vomiting, the urine and stools will be voided, and in a short time the animal will become quiet; it will become so weak as to be unable to stand; it falls about, eventually appears to be paralysed, and lies with outstretched legs breathing quietly. Dyspnœa, however, is never noticed. The corneal reflexes persist. By touching the animal or stimulating the skin reaction will occur. The paralytic stage—although often disturbed by powerful efforts at expiration, by vomiting and evacuation of stools—is marked by general depression, muscular weakness, and strange to say, by complete anuria. The animal may succumb after several hours or quickly recover and the next day be no worse for the stormy experiences above related. Sudden death is never noticed following immediately on the re-injection.

Even more remarkable results are found if observations are made on the blood pressure during the condition of hypersensitiveness. A decided fall occurs, and with this fall there is a remarkable increase of the pulse-rate and the development of a small pulse. You will recall that a blood pressure trace shows in a normal animal considerable fluctuations in the pressure curve determined by the respiration, but in the condition of hypersensitiveness such influence is gradually lost. With the recovery of the animal in some hours the respiratory influence on the pressure trace is restored to normal. Of all the above symptoms, one of the most reliable manifestations of hypersensitiveness, even when its degree is slight, is this fall of pressure.

It has been shown that this remarkable phenomenon is dependent upon vaso-dilatation, particularly of the splanchnic area, and possibly this is the explanation of the hyperæmia and congestion of the abdominal viscera which is associated with increase of the intestinal peristalsis and the evacuation of liquid stools. Lest the fashion of former physiological teaching should indicate that this is due to central disturbance of the nervous system, it is necessary to point out that really it is due to peripheral vasomotor paralysis, for adrenalin—which operates on the neuro-muscular junction—when subsequently injected is incapable of producing the familiar rise of pressure which it ordinarily brings about.

Other remarkable changes are those found in the blood—a great reduction of the coagulability of the blood and an extraordinary reduction of the leucocytes, the polymorphonuclear cells almost disappearing.

(*b*) *Guinea-pigs and Rabbits.*

Guinea-pigs show most remarkably all the above symptoms, but owing to special anatomical features of the animal it is much less easy than in the above experiments to inject by the venous route. Injections in these animals are made, as a rule, into the peritoneal cavity, and the effects are more slowly and gradually developed.

It has been possible at the hands of only some workers by intravenous injection to produce in the guinea-pig hypersensitiveness ending after a long interval in death, as in the dog. After intravenous injections the guinea-pig as a rule manifests immediate symptoms much more quickly, and we meet with sudden dyspnœa as a sign of excitation. Cramp of various groups of muscles suddenly develops—e.g., in the muscles of the chest, in the diaphragm, and in the respiratory abdominal muscles. In a short time all respiratory movements are cramp-like, and the animal dies cyanosed. A still more peculiar occurrence in the guinea-pig is the immediate rise of blood pressure, not a fall as in the dog, which soon, however, with impending death falls to nothing. The temperature in fatal cases falls, but not very much below the normal level.

The post-mortem examination of these guinea-pigs shows extreme emphysema dependent upon expansion of the alveoli, and the large and small bronchi are strongly contracted, the mucosa being plicated; this latter phenomenon has been shown to be due to cramp of the bronchial muscles. No doubt death is largely due, therefore, to asphyxiation.

If the second injection of serum is made by the intraperitoneal or subcutaneous route, the guinea-pig will still show great restlessness and terror; the urine and fæces will be evacuated, and there is developed a sort of pruritus, occasioning scratching of the skin. Dyspnœa eventually develops, and great depression, and even Cheyne-Stokes breathing, has been noted. Owing to the slower course of the hypersensitiveness in intraperitoneal injections it is possible to make more protracted observation on the temperature, and this is found to fall very considerably. Emphysema is not so exquisitely developed in these conditions. The blood pressure also constantly falls instead of rising at first. Death in such cases is not so much due to asphyxia as to the fall of blood pressure. Paralysis and coma are met with in the cases which end fatally. If the second injection is made under the skin, there may be local necrosis and hæmorrhage at the site of the first injection. A still more remarkable effect is the reduction of complement, a biological agent which abounds in this animal normally. Leucopenia and diminution of the coagulability of the blood are met with in these animals just as in dogs.

The rabbit shows similar reaction, but to a much less degree. Injections of emulsions of the organs such as the liver, kidney, spleen, &c., produce identical results if they are used instead of serum.

(*c*) *In Man.*

So far our knowledge of the symptomatology of hypersensitiveness in man is confined to the results of injections of normal or antitoxic serum when introduced subcutaneously or intravenously. Symptoms develop after a single injection

in about 6·45 per cent. of all the cases, and this group of symptoms is the expression of what is known as the "serum disease." It is not at present quite clear why there should be this natural hypersensitiveness; but it has been noted that certain asthmatic patients are rather more inclined to suffer after the injection of serum than are those free from this symptom-complex. If a second dose of serum be given a few days later (say about 10 days) then symptoms occur which are readily perceived to be due to hypersensitiveness brought about by the earlier injection.

CHART 1.

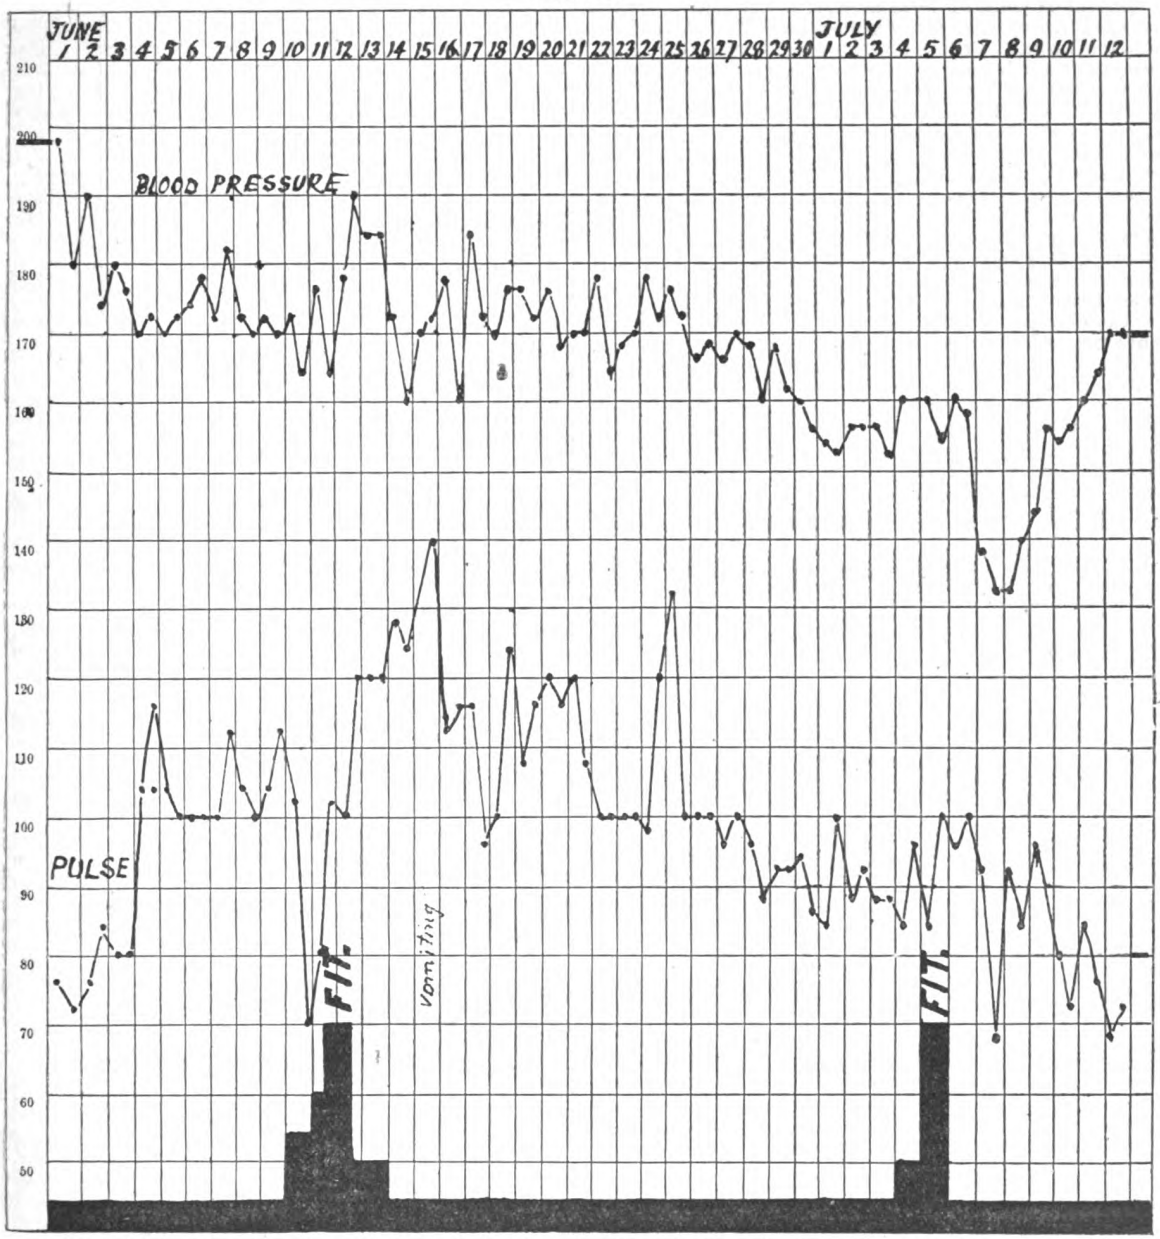

Chart of blood pressure and pulse-rate, showing two attacks of loss of consciousness. Blood pressure in millimetres of mercury.

Symptoms of the "Serum-Disease"—i.e., Symptoms following a First Injection of Serum.

These symptoms are already familiar to you. As a rule, they develop within 7–12 days after the first injection, the time depending upon the individual and upon the mass or concentration of the dose of serum. The occurrence of the symptoms has been reduced to the low figure of 6·45 per cent. by using smaller volumes of serum of a higher value than when anti-diphtheritic serum was first introduced. It is important to realise that these signs do not arise at once; there is a pre-hypersensitive period—i.e., an interval of incubation during which subtle changes are taking place within the body.

Swelling takes place at the site of the injection which is suggestive of urticaria; there is also irritation at the site of injection, and the associated lymphatic glands swell. The rash spreads and may involve the whole body and may assume the character of measles or scarlet fever, or may even be polymorphous. When general symptoms arise, all the lymphatic glands may be enlarged and may be tender.

In only 1·9 per cent. of the cases joint symptoms occur, and it has been surmised that the changes in the joints are of the same order as the skin changes. Œdema of the face may occur and may affect other parts of the body, even the glottis. Albuminuria occurs too, but is rare. Diarrhœa and diffuse bronchitis are also met with. During the incubation period, the leucocytes increase very much, and this increase

is followed by a leucopenia in which the polymorphonuclear cells are diminished. There is a rise of temperature which may last through a fortnight, but general symptoms are not marked. Complete disappearance of symptoms is the rule.

Symptoms following a Second Injection of Serum.

There is considerable variation in the symptomatology of a second injection of serum in man which depends to some extent upon the interval which elapses between the two injections.

(*a*) *The immediate effects.*—The second injection produces changes at the site of the first injection, and especially important is œdema; local necrosis is not known. There may be a rise of temperature and swelling of adjacent glands in a few hours. Urticaria with extreme irritability of the skin may be a feature. Œdema of the face occurs without albuminuria, and there is a marked leucopenia. Only very rarely is there collapse as a result of the injection. Local symptoms are more marked in children, general in adults. General symptoms usually subside in 24 hours, and local ones within two to five days.

(*b*) *The deferred or delayed effects.*—The most characteristic features develop when the second injection takes place between the forty-fifth and 180th day after the first injection. They show themselves on the fifth to seventh day after the second injection—a circumstance which should be noted because it is much shorter than the incubation period for the development of symptoms after the first injection. The symptoms of hypersensitiveness are much more marked, develop with greater rapidity, and subside also more quickly.

If the second injection takes place within six days of the first one no symptoms of hypersensitiveness occur at all. Between the twelfth and fortieth day there may be immediate effects, but no delayed ones. If the second injection takes place after the 180th day then no immediate reactions occur, but delayed ones may occur.

Analysis of the Symptoms Met with in the Condition of Hypersensitiveness.

Respiratory system.—Tachypnœa, attacks of spasmodic or irregular breathing, Cheyne-Stokes breathing, bronchitis, spasm of the bronchioles, emphysema, œdema of the lung.

Muscular system.—Spasm of certain groups, tonic or clonic, especially of those concerned in respiration. Paralysis or weakness of all muscles. Relaxation of sphincters.

Digestive tract.—Vomiting. Blood-stained, loose, and frequent stools. Increase of intestinal peristalsis.

Urinary system.—Anuria, albuminuria.

Circulatory system.—Generally marked fall of blood pressure (in guinea-pigs according to circumstances a brief rise); collapse and death (vaso-motor paresis). Frequency of pulse increased and volume reduced.

Nervous system.—Excitation. Depression. Fits, paralysis, and coma.

Cutaneous system.—Pruritus, local necrosis, and hæmorrhage (at site of injection). Localised and general œdema (without albuminuria). Morbilliform, scarlatiniform, erythematous, or polymorphous rashes. Œdema of the glottis (akin to œdema of the skin).

Blood.—Diminution of coagulability. Leucocytosis. Leucopenia. Reduction of complement.

Temperature.—Rise or fall (apparently in part due to effect of "mass dose").

Joints.—Symptoms of pains, &c.

Post-mortem investigations.—Emphysema with dilatation of alveoli. Spasm of bronchial muscles with plication of mucous membranes. Congestion of abdominal viscera, hæmorrhagic stools.

Issue.—Recovery. Death. Liability to recurrences with repetition of injection. Increase, not decrease, of sensitiveness by repetition of injection.

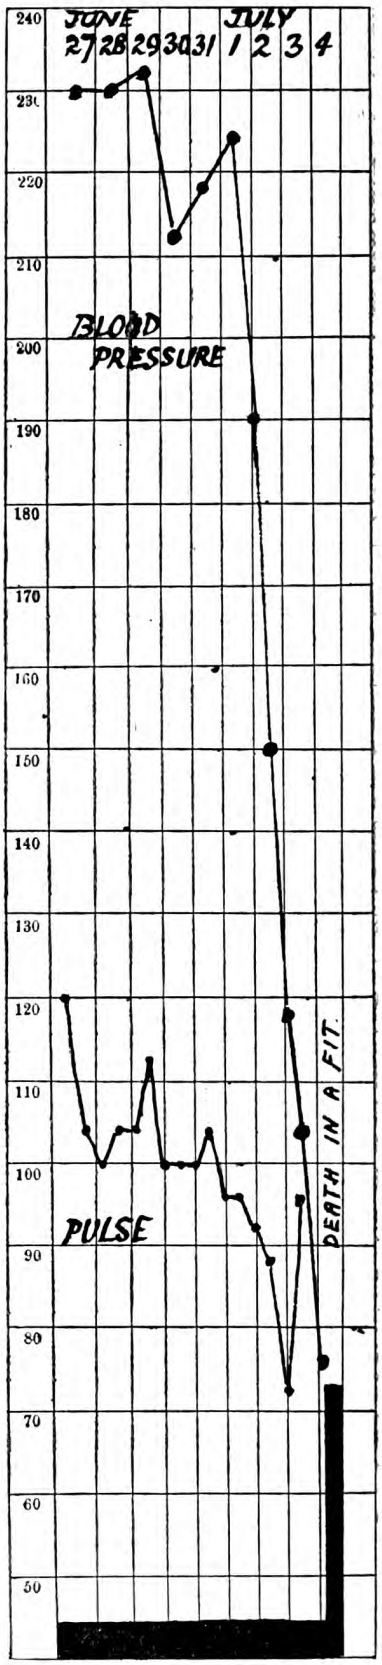
Parallel Clinical Phenomena.

We now come to considerations of parallel phenomena occurring clinically, but yet not apparently due to the introduction of protein matter intravenously or subcutaneously, or by any known route. I am going to ask you to fall back upon your clinical experiences to recall phenomena which have puzzled you and even alarmed you. You have been quite unable to explain them, and this ignorance has brought in its wake a feeling of insecurity, for you are not able to foresee their occurrence or recurrence, nor are you able to deal with them satisfactorily.

Disorders of Respiration.

The phenomena of so-called *asthma* are only too well known to any practitioner. Asthma may depend upon nasa disorders (for example, nasal polypi), upon disease of the heart (e.g., on mitral stenosis), upon renal disease, and, finally, there is a group of asthma cases which are attributable to spasm of the bronchial muscles. The mechanism by which each of these primary disorders is brought about remains a puzzle. Hay fever or the pollen disease alone has received an explanation which possesses anything like definition; the

CHART 2.



Blood pressure and pulse-rate chart, showing great fall in blood pressure preceding death in a fit.

remaining forms are unexplained or the explanations given are unsatisfactory.

Emphysema is recognised as dependent upon a variety of causes, but excluding those which appear to depend upon laborious muscular work, athleticism, the blowing of wind instruments, little has been done to explain cases in which none of these factors come into play, and they are very numerous.

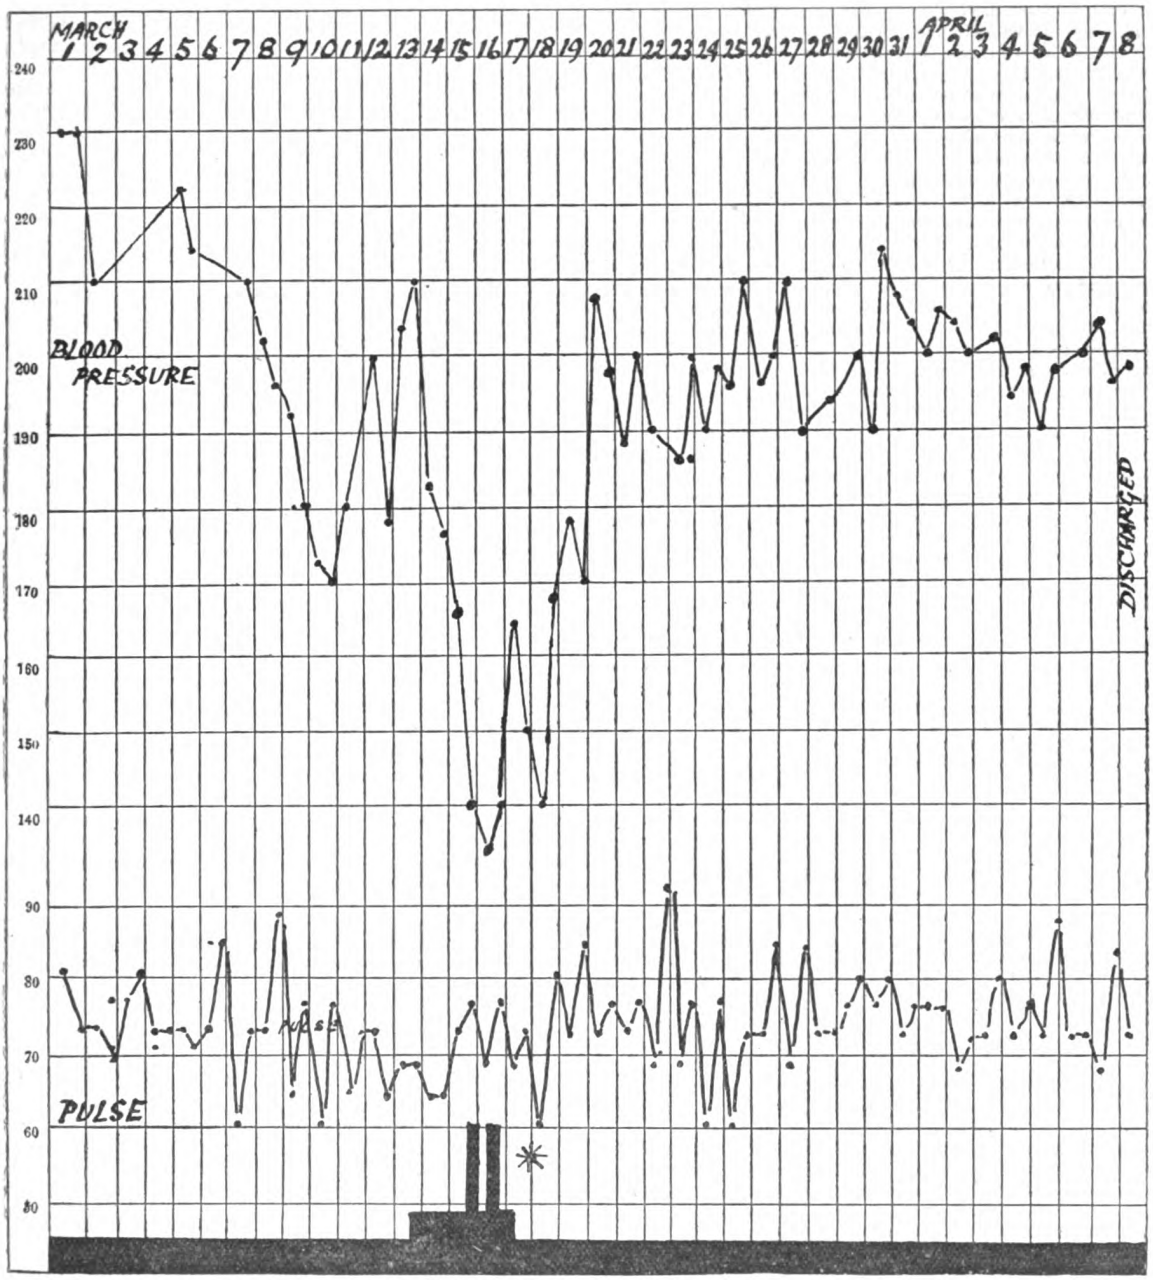
Œdema of the lung independent of infection or of the effect of irritating vapours as ether, is a common occurrence, met with in a large group of maladies, but in none so puzzling as in Bright's disease, especially in those cases in which œdema of other parts of the body is non-existent. It is possible that these manifestations are all the expressions of the existence of hypersensitiveness.

Disorders of the Nervous System, including Disturbance of the Circulatory, Muscular, and Digestive Systems.

Here, again, clinical difficulties are numerous in the extreme. Nothing can be more dramatic than the occurrence of idiopathic epilepsy. In the rehearsal of the symptoms of hypersensitiveness all must be impressed with the parallelism which many of them display with the phenomena of epilepsy. There are the initial terror and excitement of the animal, the development of actual fits, and the supervention of a sort of post-epileptic state—muscular paralysis, relaxation of sphincters, torpor, coma, and even death.

In the accompanying chart (Chart 1) there are shown observations of the blood pressure and pulse-rate of a man who had had several attacks of loss of consciousness. Fortunately, one occurred whilst in the hospital, so that close observation could be made.

CHART 3.



Blood pressure and pulse-rate chart. Two attacks o loss of consciousness represented at ✱.

The patient had had a fairly uniform high blood pressure and a perfectly normal pulse-rate up to June 1st, 1911. On and after July 12th his pressure remained uniformly still high, but at a lower level than on June 1st. Between these dates the blood pressure showed a general subsidence from a high to a less high pressure, but on July 7th, 8th, and

9th it fell to almost normal. The pulse-rate was still more remarkable in its change; for between June 1st and July 12th it rose to considerable heights, maximum 140, and was normal before and after this period.

About June 10th and July 5th he had two fits which were epileptic; he lost consciousness, had convulsions, voided stools and urine, bit his tongue, and showed post-epileptic conditions such as drowsiness. Both fits were ushered in by periods of mental instability, such as getting out of bed at odd times and walking about the wards without any reason. That he had renal disease and symptoms of tabo-paresis only helps to a small extent, because we do not know for certain how epileptic seizures which occur in these maladies are brought about, though the possible influence of choline, a derivative of nerve tissue, in the production of the seizures of general paralysis, as shown by Professor W. D. Halliburton and Dr. F. W. Mott, must be borne in mind. What we must note is that these remarkable seizures were accompanied by obvious increase of pulse-rate, and a fall of blood pressure occurred a little later than the second fit. We have seen that both these phenomena are accepted as characteristic signs in conditions of hypersensitiveness.

In cases of hypersensitiveness it is well known that a fall of blood pressure is a frequent picture in the last few hours of life. (See Chart 2.) It will be seen that there had been a great increase of pulse-rate, which had given place to slowing, and this again was followed by an increase of rate until no doubt they become so small as to be uncountable.

Striking as such pictures are, their significance is still further accentuated when we know that this patient for the last seven days of life was afflicted with diarrhœa—another feature in experimental hypersensitiveness.

Chart 3 affords still another possible example of hypersensitiveness in disease. The extraordinary fall of pressure which occurred on March 16th was accompanied by two attacks of loss of consciousness. The pulse-rate in this case showed little or no change, and, as the chart indicates, there was recovery.

Elsewhere[2] I have published results of experiments and observations which show that hypertension may be a result of the escape of kidney substance into the circulation. I may leave it to you to pass a verdict on the plausibleness of such a possibility in view of the phenomena exhibited by the patients whose blood-pressure charts have been shown to you to-day. I think it is quite possible that the experiments on hypersensitiveness give confirmation to such a view.

Cutaneous System.

To entrench upon the difficult problems of dermatology is more than could be allowed on this present occasion: but it is very much to the point to ask why it is that certain skin rashes occur and recur.

A familiar clinical picture is met with in angio-neurotic œdema. This is a common enough picture in the young, and is accompanied by fever, so that the unwary are caught and incise the area of œdema, thinking they have to do with suppuration. We have all seen such mistakes, and indeed they constitute one of the pitfalls of our days as "dresser for the week." I have seen operations done for patches of œdema in which the orbital tissue, even the tissues of the groin and scrotum, were laid open for the relief of what was supposed to be respectively cellulitis or a strangulated hernia. Rarely it happens that the œdema occurs in the mouth and tongue and even in the glottis, thereby jeopardising life. The reason for the occurrence and recurrence of this manifestation is unknown to us.

Again the reason for the development of the rashes of the acute exanthemata presents a great difficulty, no less than the explanation of the incubation periods, or as we might say the pre-hypersensitive period, which shows a remarkable parallelism in point of duration with the period which elapses after an injection of protein before the symptoms of hypersensitiveness develop. We can further hardly but wonder at the parallelism between these rashes and those of scarlatiniform, morbilliform, and polymorphous rashes met with in the "serum disease."

It is also a familiar fact that in certain cases of diffuse dermatitis such as pityriasis rubra suppression of urine closes the scene. Quite remarkable is a case I have recently shown before the Clinical Section of the Royal Society of Medicine of recurrence of asthma in a girl who also suffered from nasal polypi. With each attack of asthma, and at no other time, she had diffuse erythema of the limbs and body; the asthma and the rash no longer occurred if the polypi were removed; with their recurrence both asthma and rash recurred. Possibly either the substance of the polypi or the organisms resident upon or in them have created influences akin to those of hypersensitiveness.

Temperature.

Though rises and falls of temperature are met with in attacks of hypersensitiveness, I would especially call your attention to the fall in the accompanying chart. You will see what I believe is a possible example of hypersensitiveness brought about by vaccination. I am indebted to Dr. M. J. Rowlands for the opportunity of showing the chart. (Chart 4.)

The patient was aged 23. He suffered from pleuro-pneumonia, and the expectoration was loaded with streptococci. Four days had elapsed and there was no amelioration of symptoms. He was injected with an anti-vaccine, and, as the chart shows, by the end of 24 hours his temperature was normal, and his pulse-rate, from always being over 100, fell to the eighties. On the evening of the sixth day—i.e., 24 hours after his temperature had reached normal—it had risen to its former level. On the eighth day he was again vaccinated, and his temperature and pulse again reached normal within 24 hours and remained normal.

It is no purpose of this address to enter on the vexed question of the value of vaccination, but it appears to me that this was an ordinary case of pleuro-pneumonia, resolving on the eighth day, and that the first fall after vaccination may just as well have been a response to agencies of hypersensitiveness as to those of immunity. The patient before the first injection was charged with the products of disintegrated streptococci. Simply because he received a dose of the same material by vaccination he may be considered to have developed a condition of hypersensitiveness, and his temperature fell as a consequence. I think it is quite possible that the improvement in the temperature chart was merely an example of the working of the mechanism of hypersensitiveness, a view already enunciated by Dr. F. W. Andrewes in his Croonian lectures[3] as a result of his observations on leucopenia as a result of vaccination. It was but temporary: the next dose again restored the temperature to normal, and this was permanent and as likely as not was due to the chance synchronism of the second vaccination with the period of involution of the pleuro-pneumonic attack.

Urinary System.—The Blood.

We have seen that in animals hypersensitiveness may be accompanied by anuria and by albuminuria. The study of renal diseases shows frequently that the final stages are accompanied by scantiness and even suppression of urine with a relative increase of albumin. In certain cases this is due simply to accompanying diarrhœa and vomiting, but in others no such symptoms occur. The occurrence even of diarrhœa and vomiting in uræmia also provokes an inquiry whether they are symptoms of hypersensitiveness.

I am not able to offer you examples showing the alteration of the leucocytes or the fall of complement in cases occurring at the bedside, but I would refer you to Dr. Andrewes's observations on leucopenia in vaccination mentioned above.

Correlation of the above Clinical Symptoms with Phenomena of Hypersensitiveness.

I now come to the part of my task which is most difficult. So comparatively new is the subject of hypersensitiveness as a possible explanation of bedside symptoms, and so scanty are the clinical investigations which support the idea, that at present it is little more than an ingenious surmise to say that the mechanism of hypersensitiveness has anything to do with the various clinical manifestations above cited.

Returning to the opening remarks of this address, it will be remembered that hypersensitiveness has been demonstrated experimentally by the introduction of proteins of animal (or vegetable) origin into the body of an animal, other than the animal from which such proteins were derived, by a route other than the alimentary tract. How could it be argued that symptoms occurring in man could ever be dependent upon such circumstances? In the case of bacterial proteins the task is easy, and already there are several papers calling attention to the possible explanations

[2] THE LANCET, 1906, vol. i., pp. 1295, 1375, 1455.

[3] THE LANCET, vol. i., 1911, p. 1737; vol. ii., pp. 8, 83, 153.

of the recrudescences, &c., of the temperature in pneumonia and typhoid fever, of the incubation periods of the acute exanthemata and the development of their respective rashes, by a reference to the theory of hypersensitiveness.

Is there any justification for thinking that clinical manifestations which are independent of infection could possibly be due to the same mechanism? Attention must be called to the well-known existence of sclerosis of certain organs such as the liver, kidney, and brain. The parenchyma of these organs has disappeared and been replaced by fibrous tissues; the dislocated tissues may readily reach the vascular system.

It is therefore possible that subjects who suffer from these disorders, in which sclerosis and loss of parenchyma are features, have been rendered hypersensitive to their own organs.

But the objection may be raised that so far as animal experiments have been detailed to you, none have been concerned with the production of hypersensitiveness of an animal to its own organs. Fortunately, however, such experiments have been made, and with positive results. On the high authority of Uhlenhuth, characteristic symptoms of hypersensitiveness are developed when an animal, the guinea-pig, after the intravenous injection of an emulsion of one of its own lenses, is three weeks later injected with an emulsion of its remaining lens. V. Dungern and Dunbar, Gräfenberg and Thies have shown the same thing by the injection of an animal's own spermatozoa.

These experiments then give great support to the view that in clinical medicine certain unexplained phenomena may after all be due to the mechanism of hypersensitiveness. It may be that asthma, epileptic seizures (for example, those found to follow upon infantile hemiplegia), the coma met with in cirrhosis of the liver and granular kidney, "uræmic" palsies, "uræmic" fits, "uræmic" diarrhœa and vomiting, various forms of local or general œdema occurring independently of albuminuria and kidney disease or other ordinarily accepted cause, the convulsive seizures of general paralysis, eclamptic convulsions or the coma met with by your secretary occurring just after confinement in a woman otherwise apparently quite healthy, may all be examples of hypersensitiveness.

It has been found that if an animal is injected with the serum of an eclamptic woman, and two days later is injected with amniotic fluid, "hypersensitive" phenomena develop. They do not do so in a guinea-pig not previously injected with eclamptic serum. From which it may be concluded that possibly an eclamptic woman is really suffering from absorption of amniotic fluid; her serum develops changes as a result, and such changed conditions are communicated to the animal into which such serum is injected; it becomes "passively" hypersensitive, so that on injection of amniotic fluid the phenomena of hypersensitiveness are revealed.

Recurrent œdema of the lungs independent of an infection, even emphysema itself not dependent upon excessive muscular exercise, recurrent hemi- and monoplegia, which are entirely recovered from, and which can be traced to no known cause, the excitation and depression which are such marked features in insanity, pruritus, and the many unexplained skin manifestations such as urticaria, also may be due to hypersensitiveness. The proteins responsible for the production of these phenomena may be derived from the individual so afflicted.

This list of clinical manifestations may appear to you as an ambitious one. The dissatisfaction we all feel when asked to give an explanation of them, however, in terms of pathological principles which have been accepted in the past, must be the excuse for my offering to you explanations based upon newer theories. If the proof is meagre at present, yet the impetus given to clinical study is one which promises much for the future. For further information—indeed, for the sources of all the theoretical considerations put before you this evening—I would refer you to an address by Dr. W. D'Este Emery on Anaphylaxis,[4] and to two luminous and suggestive articles by Dr. Friedberger,[5] whose views I have described.[6] For further references I mention monographs by Pfeiffer,[7] Moro,[8] and Besredka and Biedl and Kraus.[9]

Harley-street, W.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The annual meeting of this institution will be held at Devonshire House, Piccadilly, on March 29th at 3.30 P.M. The Duchess of Albany has signified her intention of being present, and Earl Curzon of Kedleston has promised to make an appeal on behalf of the financial needs of the hospital.

THE BED ISOLATION OF CASES OF INFECTIOUS DISEASE.

BY C. RUNDLE, M.D. LOND.,
MEDICAL SUPERINTENDENT, CITY HOSPITAL, FAZAKERLEY, LIVERPOOL;
AND
A. H. G. BURTON, M.D. LOND.,
SENIOR RESIDENT MEDICAL OFFICER, CITY HOSPITAL, FAZAKERLEY, LIVERPOOL.

IT is the practice to admit to the Fazakerley City Hospital patients suffering from the infectious illnesses commonly admitted to hospitals of this character. In addition to scarlet fever, diphtheria, and typhoid fever, there are during the greater part of the year under treatment at one time cases of erysipelas, puerperal fever, measles, chicken-pox, and infantile diarrhœa. To these may be added a variety of conditions admitted under a mistaken diagnosis, the nature of which will be familiar to those who have been responsible for the administration of large fever hospitals. In addition, 60 beds are set aside for the sanatorium treatment of consumptives. There is in all accommodation for 520 patients.

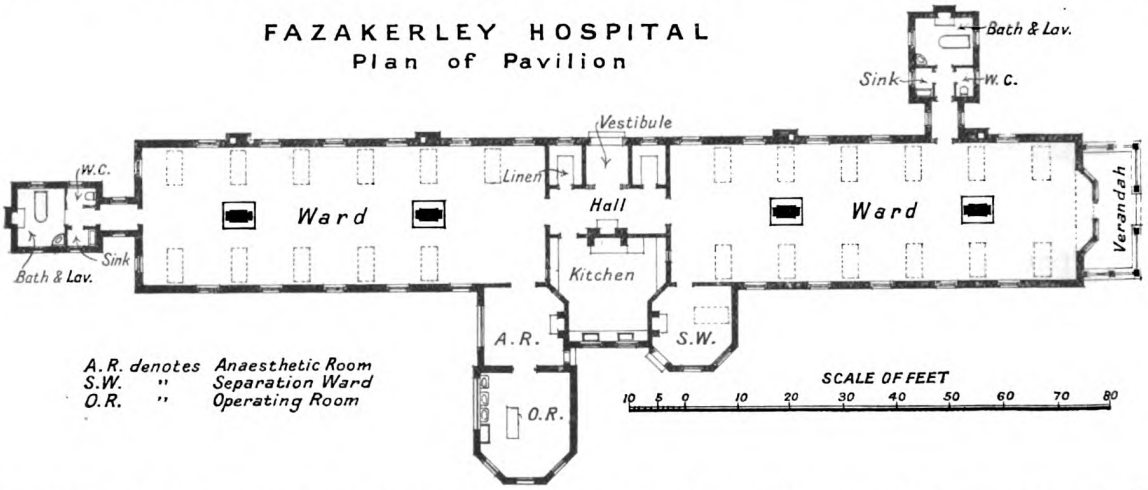
The requirements of modern methods of nursing, the separation of acute patients from those more convalescent, the isolation of those suffering from septic complications, and the large proportion of patients admitted under the heading of "Other Diseases," make it impossible to reserve to each variety of infection a pavilion for the purpose of that infection only, the structural and administrative cost would be obviously prohibitive. As an alternative to a strict limitation of the number of diseases admitted for treatment, with a corresponding restriction in the utility of the hospital, the following systems have been practised in various institutions whereby patients suffering from different infections may be brought administratively under the control of a limited number of nurses: (1) Treatment in separate rooms opening on to a common duty room—i.e., the system of isolation nests; (2) the glass cubicle system; and (3) the system of bed isolation whereby patients suffering from different infectious diseases are treated in the same ward under the same nurses, measures of strict asepsis alone being relied upon for the prevention of cross infection. The results obtained from a somewhat extensive trial of this last system made during the years 1910 and 1911 at the City Hospital, Fazakerley, form the subject of this paper.

The necessary administrative and economic disadvantages attached to the system of isolation by separate wards need not be noticed here; structural changes in many directions have been made with a view of minimising these difficulties, and the glass cubicle system may be regarded as the most recent attempt to provide a physical obstacle to the transmission of infections at a reasonable administrative cost. This method, although of great value, has limitations (apart from initial cost of construction), which have been readily admitted by those who have had experience of its use, and the object of the investigation made at this hospital has been to show whether nursing on lines of strict surgical asepsis might safely take the place of the structural methods hitherto adopted.

The principles of the bed isolation of cases of infectious disease have been observed for a number of years under the system of "barrier" isolation, but the practice of this system has been reserved in the majority of instances for the separation of different types of the same disease. By this method, for example, septic types of scarlet fever have been effectively isolated from types of a less severe character, and children have been separated from their fellows during the incubation period of a secondary infectious disease to which they have been exposed. No investigations have hitherto been made on a scale sufficiently extensive to be of value to suggest how far these same principles might be safely utilised in the separation of patients suffering from a variety of different specific infectious diseases.

The ward pavilion used for the purpose of this work has male and female wards separated by an entrance hall, kitchen, pantry, and linen cupboard (see figure). The female ward has a roofed verandah at the south end, the sanitary offices being placed at the side, while the male ward has its lavatory accommodation at the extreme north end. The beds are arranged on the ordinary plan with a window between each bed. The air-space in cubic feet per patient is 2100. Opening out of each ward of the pavilion is a small observation ward with an inspection window to each from the kitchen; that on the female side is of the usual type accommodating one bed and a cot and has an outside door. On the male side the isolation ward has been converted into an anæsthetic room; it holds one bed and opens into a large and well-appointed operating theatre. The remaining appointments of the ward require no further description, being of the usual type found in isolation hospitals.

FAZAKERLEY HOSPITAL
Plan of Pavilion



The diseases which are admitted to the ward are as follows: (1) All cases of puerperal fever and erysipelas, and most cases of pertussis, rubella, and varicella; (2) all cases notified as suffering from an infectious disease, but found on admission to have no infectious condition; (3) cases in which the diagnosis is doubtful and observation is necessary, such as "query" scarlet fever or diphtheria cases; (4) cases from other wards in the hospital requiring operative treatment in which the after-treatment may be prolonged; (5) convalescent cases of diphtheria or measles when the wards receiving these patients are pressed by a sudden rise in the incidence of the disease; (6) cases of epidemic diarrhœa when these are few in number. The method of isolating these various diseases in one ward has been, in brief, the observation of strict cleanliness after examining or attending to a patient with a primary infectious disease or suspected to be suffering from such.

The hospital has had the advantage of possessing a highly trained sister in charge of the ward pavilion with special surgical and fever experience, who has supervised the wards since their inception. Each ward, male and female, is in charge, under the sister, of a general hospital-trained nurse with some fever experience; one probationer is also allocated to each ward. The night staff consists of two nurses, one of

whom has frequently had three years' general training. The wards are consequently well staffed both as regards the number and the qualifications of the nurses in charge. Each case of puerperal fever is placed on admission in the side ward off the operating theatre until it is decided what operative measures, if any, may be required. As long as active treatment, such as douching, is required the nurse in charge is not allowed to assist in the dressing of any case of erysipelas or cellulitis. Coats are worn by the doctor and nurse when attending to the case, and rubber gloves if douching or dressing is needed. When the operation has been performed and another case has been admitted requiring operative treatment, the first case is transferred to the main ward. Thus during the same week there were six cases of puerperal fever in the main ward and one case in the side ward.

The cases of erysipelas and cellulitis are treated with ordinary cleanliness only, no special isolation measures being adopted. The same remark applies to patients having no infectious disorder but some such condition as lobar pneumonia or a non-infective skin disease.

With cases of varicella, pertussis, and doubtful or genuine cases of scarlet fever or diphtheria, more rigid measures are adopted. Two long coats kept for each case are worn, one by the doctor and the other by the nurse, whilst examining or attending to the patient. Drinking-vessels, knife, fork, spoon, and spitting-mug are boiled after use, and separate sanitary utensils, bowl and brush for washing, and bath blankets are reserved for the use of each of these patients. No interchange of toys or books is permitted. After removing the coat worn in attending to the case the doctor or nurse washes the hands before proceeding to another patient. For this purpose a table with three bowls is kept half-way down each ward; additional bowls are placed on the locker of the patient concerned if isolation measures are likely to be prolonged or if the case is requiring frequent attention.

Temperatures are taken in the axilla and the thermometers washed in lysol after use. In the case of patients suffering from varicella or enteric fever a separate thermometer is kept for each patient.

If the case is one of the prime infections mentioned this routine is adopted until the patient is considered non-infectious, in cases of doubtful diagnosis until a negative opinion is arrived at. The patient is allowed to get up when all signs of acute disease likely to prove infectious have subsided. From now on he is allowed to mix freely with the other convalescent patients until discharged, provided that he is not a scarlet fever or diphtheria patient with rhinorrhœa or otorrhœa, in which cases a longer stay in bed is adopted, in the former case until the rhinorrhœa has ceased. Special precautions are, of course, adopted in dealing with nose or ear discharges. The convalescent transfers from other wards are similarly allowed freely to mix with the convalescent patients of the ward.

The total number of cases admitted to the ward during the years 1910 and 1911 was 668. Of this number, as will be seen in the following table, 27 showed no actual disease; a large proportion of these 27 cases were babies admitted with their mothers, the latter suffering from puerperal fever.

Table giving Varieties of Cases Admitted during the Years 1910 and 1911.

Infectious Diseases.

Disease.	Total cases.	Convalescent transfers.
Scarlet fever	69	16

No disease.—27.

During the two years under review the number of patients who developed an infectious disease whilst under treatment was two. One instance occurred in a girl, aged 7 years, who had been admitted suffering from rubella, but notified as a case of scarlet fever. After 14 days' stay in bed she was allowed up, but 13 days later was again confined to bed with a typical attack of scarlet fever. The other secondary case was that of a girl, aged 10 years, admitted with a mild attack of faucial diphtheria. After 28 days in bed she was allowed up, and in six days' time developed scarlet fever.

In the list of cases given attention may be drawn to the large number of non-infectious patients, many of whom—as, e.g., those sufferiug from epidemic diarrhœa—were young children. None of these contracted any infectious disease while in the ward.

The above figures represent the result of two years' observation, and although not large they certainly justify a continuation of this work and support the opinions arrived at by Martin, of the Institut Pasteur, Crookshank,[1] and others.

Caiger[2] in a recent paper defines three methods by which infection may be transmitted from one patient to another, both occupying beds in a hospital ward: 1. By "direct projection of infective particles from the patient's mouth or nose, the recipient being in immediate proximity." 2. By "mediate infection"—i.e., the indirect conveyance of recent infective material from the patient to the recipient by means of some article common to both. Under this heading may be included spread of infection "by fomites." 3. By "aerial infection"—i.e., infection at a distance (such as that intervening between neighbouring beds) by means of minute droplets of saliva, mucus, &c.

A consideration of the results obtained by bed isolation compared with those of cubicle isolation should be of definite value in deciding upon the comparative importance of these three modes of infection. Facilities for the spread of infection by method (3)—i.e., aerial infection—are obviously greater under the system of bed isolation than that of cubicle isolation; in fact, a total breakdown of the system of bed isolation might be expected if "aerial infection" were of common occurrence. In the light, however, of the very satisfactory results obtained by this latter system, as compared with those of cubicle isolation,[3] it may be fairly argued that the danger of spread of infection in a hospital ward by means of "aerial infection" is to be disregarded for practical purposes. It would appear that the practice of rigorous asepsis on surgical lines has a value equal to, or greater than, that of any of the accepted methods of separation by artificial barrier.

If the suggestion be accepted that "aerial infection" is a factor of limited importance, a suggestion receiving support from the results of this investigation, it may be questioned whether glass partitions do not involve a false security in regard to the nursing staff, rather than that protection to the patient which is claimed for them. In short, it would appear that in this matter of individual or "unit" isolation, the quality of nursing obtainable is the sole factor of success or failure. In probably no other branch of her professional work is a nurse called upon to display so large a capacity for detail and administrative control as in the bed isolation of cases of infectious disease.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TWO CASES OF "ACUTE ABDOMEN."

BY J. J. W. EVANS, F.R.C.S. ENG.,
MEDICAL OFFICER IN CHARGE, WESTMINSTER HOSPITAL.

THE following two cases are of interest because they show the extreme difficulty of diagnosis in atypical abdominal conditions. A perusal of them will demonstrate their extreme similarity in all clinical aspects and their great divergence in pathological detail.

CASE 1.—A single woman, aged 45, was admitted to the Westminster Hospital in December, 1911. In the past she had had two attacks of "gastric ulcer" in 1906 and 1910, being laid up in the first instance five and in the second three months; in both instances she suffered from severe abdominal pain and persistent vomiting. She also had pleuro-pneumonia in 1907. There was a history of dysmenorrhœa as a young woman, but she had not suffered of late years. Two days before admission she was suddenly attacked with acute abdominal pain and vomiting which persisted up to the time of admission. When first seen the patient had a temperature of 99·4° F. and a pulse rate of 136; she had been given morphia before the journey. The abdomen was a little distended and only moved slightly on respiration; there were general tenderness, most marked on the left side, and absolutely no rigidity or any sign of fluid in the abdominal cavity. The pelvis was normal. The liver dulness was diminished. The heart and lungs appeared normal. A diagnosis of perforated gastric ulcer was made and laparotomy was performed. An incision was made in the middle line above the umbilicus but nothing abnormal was found in the upper part of the abdomen, which was then further explored below with a like result. The wounds were closed and the patient put back to bed, where her pulse-rate immediately fell to 120. With the exception of two days' pain and vomiting the patient made an uneventful recovery.

CASE 2.—A married woman, aged 34, with one child and no miscarriages, was admitted in December, 1911. Her past history showed that she had been laid up for a fortnight with "gastric ulcer" in 1903. Three days before admission she developed pain in the abdomen, most marked on the left side; there was no vomiting and the bowels were confined. When admitted the patient had a temperature of 100·8° F. and a pulse-rate of 132; morphia had been administered before the journey to hospital. The abdomen was not distended and moved on respiration; it was very tender all over, but there was no resistance or any sign of free fluid. The pelvis seemed normal. The liver dulness was present. The heart and lungs were examined and presented no abnormality. Laparotomy was performed, the incision being made in the middle line below the umbilicus. The abdominal cavity was found to contain a large quantity of pus distributed all over it; there was also an abscess cavity in the pelvis which had burst and contained a gangrenous appendix. The appendix was removed and the abdomen washed out and drained. Pus from the abdominal cavity showed on cultivation the streptococcus pyogenes and the bacillus coli communis. The patient made a slow but good recovery. The circumstances of both cases were such that no leucocyte count was possible.

The first case shows very well the impossibility of making a certain diagnosis in some abdominal conditions, which are fortunately of rare occurrence. The anomalous nature of the physical signs in the second case may have been accounted for by the recent administration of morphia. But however one may regard such cases one is forced to admit the advisability of prompt treatment.

I wish to express my thanks to the staff of the hospital for permission to publish these reports.

A CASE OF SURGICAL EMPHYSEMA DURING LABOUR.

BY MARION STOCKS, M.B., B S. LOND.,
ASSISTANT MEDICAL OFFICER, SHEFFIELD UNION HOSPITAL.

THE patient was a strong healthy girl, aged 20 years, a primipara, who had been in the Sheffield Union Hospital during the last two months of pregnancy.

Labour began on Feb. 14th at 1.30 A.M. when it was found that the vertex was presenting. Dilatation was complete and the membranes ruptured at 10.30 A.M.; the presenting part, however, remained high up in the pelvis. The uterine contractions were good and were supplemented by the strong voluntary efforts the patient herself made during the second stage. She had also frequent attacks of vomiting.

When seen at 2.5 P.M. her general condition was satisfactory, and the head was then beginning to make pressure on the perineum. Very shortly afterwards, however, the maternity sister reported that the patient's face was swelling, that this increased and was accompanied by cyanosis during the pains. The crackling sensation of subcutaneous emphysema was found present over the swollen area, extending over the neck and right side of the face; the right palpebral fissure was reduced to a slit. Forceps were applied and the patient was delivered of a living child.

At 10 P.M. the emphysema was found present over an area including both sides of the neck, both sides of the face up to the orbital ridges, the whole of the right side of the thorax limited by the costal margin below, the spine behind, and the sternum in front; the right upper arm to the extent of a third, and the left shoulder. Apart from some pain in the chest and at the back of the neck, of which complaint was made, the patient appeared to be little the worse. She made a good recovery, the whole of the swelling having disappeared at the end of eight days.

Sheffield.

A CASE OF MENINGITIS IN WHICH THE BACILLUS COLI COMMUNIS WAS OBTAINED FROM THE CEREBRO-SPINAL FLUID.

BY G. H. PEARSON, M.R.C.S. ENG., L.R.C.P. LOND.

A GIRL, 3 months old, was admitted to the East London Hospital for Children, Shadwell, E., on Jan. 25th, 1912, with obvious signs of meningitis. Lumbar puncture was performed under strict aseptic precautions and a turbid fluid, not under tension, was withdrawn. On examination four hours later the fluid showed numerous bacilli, extra- and intra-cellular, and a large number of polynuclear neutrophiles. A white count the same day as the puncture was done showed the number to be 16,000 per cubic millimetre.

The child died six days after admission, and at the post-mortem examination the diagnosis of septic meningitis was proved to be correct. The brain was entirely covered—more especially the anterior two-thirds—with purulent and offensive pus. There was no localisation of pus at any point. The ventricles were dilated and full of pus, which also surrounded the cord, especially between the cervical and lumbar enlargements. The left middle ear was full of pus, while the right was healthy and dry. No thrombosed vein or caries of bone was found. During life no symptoms of middle-ear mischief had been present. The bacillus, which was remarkably plentiful in the cerebro-spinal fluid, had all the morphological and cultural characteristics typical of the colon bacillus.

Cases of meningitis due to the colon bacillus are of great rarity, and there is little doubt that in some of the recorded cases the bacillus was found either as a result of a contamination in performing the lumbar puncture or as an ante-mortem phenomenon. In this case an obvious focus of entry for the bacillus was found post mortem, and the fluid withdrawn during life was examined shortly after removal from the body and found swarming with bacilli.

In the cases recorded by D'Allocco,[1] Nobecourt and Du Pasquer,[2] and Concetti,[3] where the bacillus was obtained from cerebro-spinal fluid by lumbar puncture, meningitis was

accompanied by very severe gastro-intestinal disturbances. Recovery is reported in most of the cases. In this case, however, these symptoms only appeared at the close, and there seems no doubt that the primary focus was the middle ear. Forbes[4] also mentions a case of spina bifida from which he obtained the colon bacillus from the cerebro-spinal fluid. The child recovered.

I am very much indebted to Dr. A. M. Gossage, under whose care the child was, for permission to publish the case, and also to Dr. P. N. Panton, of the London Hospital, for his kindness in confirming the cultural results.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Fibrinous Discharge from the Nose.—Ruptured Intestine.—Exhibition of Cases.

A MEETING of this section was held on March 8th, Mr. W. G. SPENCER, Vice-President, being in the chair.

Dr. A. M. GOSSAGE read a paper entitled, "A Family with Fibrinous Discharge from the Nose." He pointed out that fibrinous rhinitis was not very uncommon in children. According to Lambert Lack it was commonest in early childhood and was ushered in by slight malaise which was not sufficient to cause the child to lie up and only lasted for a day or two. There was a nasal discharge associated with fibrinous or membranous exudation on the nasal mucous membrane which persisted for six to eight weeks and then cleared up, leaving no sequelæ. In nearly all the cases bacilli indistinguishable from the Klebs-Löffler bacillus could be found, but although the disease was infectious, it did not seem to give rise to true clinical diphtheria. True diphtheria, of course, invaded the nostrils not infrequently and gave rise to a severe illness with formation of membrane in the nose. A further type of membranous formation in the nose had been described by Baumgarten. A strong baby girl had been noticed from birth to have crusts about the nose. With a probe and wool a long thin tube, like parchment, could be obtained from the nostrils, which took three to four days to re-form. At the age of 3 years a bad smell had been noticed, and after 4 years typical ozæna had developed. When the child was 2 months old the nose had been washed out with iodoglycerine, and after this no more tubes were formed, but occasionally there were slight crusts; later even these disappeared. The mother had suffered from ozæna, but there was no other abnormality in the family; a twin sister was quite normal. Baumgarten further stated that he had met with two other similar cases: tube formation in early infancy and development of ozæna about the fifth year of life. He considered that ozæna is frequently inherited chiefly from mother to daughter, and is much commoner in women. Dr. Gossage had recently come across a remarkable family, several members of which had a persistent fibrinous discharge from the nose. The condition was first noticed at birth and apparently persisted throughout life. It caused no impairment of health, the bronchitis from which the first member he had seen was suffering having been probably an accidental concomitant. There was only very slight discomfort, though there was a tendency to the development of a bad smell if the nostrils were not kept clear. In no case, however, was there any sign of ozæna. Specimens of the discharge, which usually took about 12 hours to re-form, were obtained from the father and two of the children, and in all cases were found to be a more or less complete fibrinous cast of the nostrils. Dr. Ross, pathologist to the East London Hospital for Children, had kindly examined the discharge and reported as follows: Film preparations showed polymorphonuclear cells embedded in a network of fibrinous matter. The organisms present were bacilli, diplococci, and short diplo-bacilli; no evidence of bacillus diphtheriæ or bacillus xerosis. Attempts to embed in paraffin and cut sections failed owing to the friability of the material. One of the boys had been taken into the hospital for 24 hours, but unfortunately had no discharge during that time. The nostrils had been examined on several occasions, and nothing abnormal could be seen, except once, when some fibrinous exudation was found over one lower turbinate bone. At least four generations had been affected, and males and females were attacked equally. Of the children of affected persons with normal mates, roughly half were affected and half normal. This suggested that the inheritance afforded another example of Mendelism in human beings, and that the abnormal condition was dominant to the normal. Unfortunately, there was no record of any offspring from the normal members of the family, so that it was impossible to say whether all their children were normal, as would be expected. It was a matter of great interest to find a fibrinous exudation on a mucous membrane resulting from a congenital abnormality, and not from some infective inflammatory process. He had not been able to find any record of a similar condition in medical literature.

Mr. WILFRED TROTTER communicated a note on a case of Ruptured Intestine, with especial reference to the mode of production of the lesion. The case was one which appeared to throw some light upon a subject about which there had been some controversy—viz., the mechanics of the production of traumatic rupture of the intestine. The patient, a youth, aged 18, was admitted to the University College Hospital during the evening of August 30th, 1910. Some hours earlier, in the course of his work as a navvy, he was caught between the buffers of two ballast wagons and severely crushed. The wagons being a good deal lower than ordinary railway trucks the buffers caught him over the lower half of the abdomen. He was held by them for a few moments under severe pressure. Operation was undertaken somewhat less than 24 hours after the accident. A median incision was made below the umbilicus. The intestinal coils in the lower half of the abdomen were found to be inflamed and somewhat matted together. Amongst them was turbid fluid mixed with a considerable quantity of fæces. Separation of the coils revealed a segment of ileum lying to the left of the spine against the posterior abdominal wall and showing an opening half an inch across which was discharging semi-solid fæces of a green colour. Examination of the damaged loop showed at once that suture was not possible. Enterectomy was therefore done and the bowel united end to end. The features of the injury could be seen well in the specimen shown, which preserved most of the appearances visible at the operation, and in a drawing. For a distance of about 2 inches the peritoneum of the bowel had been torn through and had shrunk back. Through this opening the tube of mucous membrane had protruded after being torn away from the outer coats. In the most prominent part of the prolapsed mucous membrane was a round opening of the size of a sixpence. The appearances seemed to show that the lesion was produced by a true bursting of the intestine. Traumatic rupture of the intestine had been attributed, and no doubt was due, to the action of one or other of three different mechanisms—viz., crushing, laceration, and bursting. There was no doubt that one or other of the two former caused the lesion of the bowel in many cases. Upon the third, however, a good deal of doubt had been thrown, and some authorities were inclined to question whether it was ever a cause of rupture. Experiments had shown that when the abdomen was compressed the pressure within the bowel, as might have been expected, was not increased above the general intra-abdominal pressure, and that therefore there was no tendency for bursting of the bowel to occur. When, however, a loop of bowel was not supported by the general intra-abdominal pressure—when, that is to say, it lay at a hernial opening or within a hernial sac—rupture was likely to occur if the abdomen was violently compressed. It had been shown comparatively recently that the influence of a hernia in predisposing to the occurrence of rupture was an important one. While admitting this, he was not prepared to agree that bursting could occur only in presence of a hernia. None such was discoverable in his case. It seemed, however, that bursting might be brought about in another way. If a loop of bowel were caught between the compressing force and the spine in such a way that both limbs of the loop were occluded, the contents of the latter might be put under such pressure that bursting occurred. Some such mechanism as that appeared

[4] Quarterly Journal of Medicine, Oxford, 1908, vol. i., p. 109.

to be the explanation of the state of affairs found in his case.

Dr. JAMES GALLOWAY showed a case of Progressive Muscular Dystrophy. The patient, a man, aged 31, presented the characteristic features of the better known types of this disease. The case was noteworthy on account of the want of evidence of heredity, the late onset of symptoms, the possible influence of severe muscular exertion, the arrest or retardation of the disease for some years, and the advance of symptoms when, for a transient illness, he stopped exercise and remained in bed for a fortnight.

Dr. HERBERT FRENCH showed a case of Paralysis of the Right Vocal Cord, Obstruction to the Superior Vena Cava, and Partial Obliteration of the Right Radial Pulse from Mediastinal Fibrosis, probably Syphilitic. The patient began to suffer from fulness in the head and from congestion in his upper extremities, with consequent difficulty in doing his work. The symptoms rapidly increased, and for upwards of a year he was unable to do any work, all the veins of his forehead, face, neck, and arms standing out like cords on the least exertion, and his facies presenting the suffused and livid appearance of considerable venous obstruction. During the past year these congestive symptoms had diminished sufficiently to allow him to do light work, probably as the result of the development of a deep collateral circulation. There was no marked degree of fulness of his superficial thoracic veins when he did not work or when the weather was cool, but on working, or when the weather was hot, many dilated superficial veins stood out upon his chest wall, his arms, neck, and forehead. The upper part of his right chest and shoulder were filled out as though by a tumour, especially at the root of the neck above the right clavicle. The patient had a bovine cough, and there was paralysis of the right vocal cord. The right radial pulse was hardly perceptible, whilst the left was strong. X ray examination showed no bulging of the aorta, but a dense shadow in the superior mediastinum, and particularly upon the right side, corresponding with the fulness that could be felt there. Malignant neoplasms would seem to be excluded by the facts that there had been improvement during the last year, and that the duration had already been two years without any loss of weight. Benign neoplasm within the thorax was a possibility; but the patient when a young man had syphilis and gave a positive Wassermann reaction when he first came under observation, so that it was thought that the lesion was mediastinal fibrosis from the healing of former gummata within the thorax, leading to stenosis of the superior vena cava, stenosis of the innominate artery or right subclavian artery, paralysis of the right recurrent laryngeal nerve, and interference with the upper lobe of the right lung. There was apparently no interference with the nerves of the brachial plexus.

Dr. FRENCH also showed a man; aged 61, who had Two Aneurysms of the Thoracic Aorta.

The following cases were also shown:—

Mr. ALBERT CARLESS: A case of Sarcoma of the Ilium treated by Coley's Fluid.

Mr. W. H. BATTLE: A case of Mikulicz's Disease.

Mr. TROTTER: Two cases illustrating Rupture of the Extensor Tendon of the Terminal Phalanx of the Finger.

Dr. E. B. WAGGETT and Mr. EDWARD D. DAVIS: A case of Hyperostosis Cranii.

SECTION OF ANÆSTHETICS, WITH SECTIONS OF SURGERY AND MEDICINE.

Exophthalmic Goitre.

THE adjourned debate on this subject took place on March 5th, Dr. W. J. MCCARDIE, the President of the Section of Anæsthetics, being in the chair.

The debate was resumed by Mr. A. E. BARKER. He said that though he had operated upon a large number of cases of thyroid tumour of all kinds, and in various positions, he had only dealt with a limited number of cases of Graves's disease. Though he had listened, in Berlin five or six years ago, to Professor Kocher's analysis of his work in this sphere, and the discussion which followed it, and had studied the literature since, he did not feel that a strong case had yet been made out for the operative treatment of Graves's disease, and the able contributions to the present discussion had not materially modified his views. Indeed, the ingenious way in which Dr. Hale White put the matter at the first of these meetings[1] had greatly strengthened the feeling he originally had. The intrinsic difficulties of the operation were a deterrent, and the effect of thyroidism on the nervous system was such that the liability to shock was much increased. It seemed that the mortality from Graves's disease when it was treated medically was about double that of ordinary people of the same age not suffering from exophthalmic goitre. The mortality from operations for the condition was variously given as from 4 to 10 per cent. The latter figure was Mr. Wilfred Trotter's,[2] and was about what one would expect from the operation. For most of his thyroid operations he had relied upon local analgesia, and had been well satisfied with it, though his experience comprised but few cases of extreme degree. This method should always be combined with morphia or some other efficient general sedative. The infiltration should be done by a surgeon who was familiar with the ground which he would have to cover, and the amount of force which would be necessary for the dissection. In conclusion, he spoke highly of the great help given to the surgeon by the expert anæsthetist.

Mr. CHARTERS J. SYMONDS regarded this discussion as forming an epoch in the operative surgery and general treatment of exophthalmic goitre. Dr. Dunhill's paper[3] seemed to convey a too great feeling of safety with regard to the operation itself, and he (Mr. Symonds) insisted upon the need of differentiating between patients who were nervous and had a goitre and patients with true hypothyroidism. Finer distinctions were necessary, based upon a closer examination of other organs of the body and of the blood. There was room for a more frequent consultation between physician and surgeon in selecting cases, and operating upon only the suitable ones. If cases could be seen earlier, he had hopes that operation for Graves's disease would become as safe as that of ordinary thyroidectomy. He feared that, in a general way, there was at present too strong an inclination to operate, and the blame for that must not be given wholly to the surgeon, for he was sometimes asked to open an abdomen because the physician was not ready to rest upon the obvious symptoms. There were some operations which, in order to insure safety, needed to have been frequently performed by the particular surgeon, who should possess the experience gained from operating in general and not alone in one particular region. This skill and knowledge would enable him to know how to act when his first course failed. He still looked upon operations for exophthalmic goitre as very serious, and much remained to be learned before success could be commanded. In all the cases of goitre, except two, which he had operated upon chloroform was the anæsthetic, and he had not had anxiety about them.

Mr. DONALD J. ARMOUR gave his experience in connexion with 26 cases, all but two of whom were females. He had had one operative death, and that patient should not have been operated upon, as she was in the last extremity of the disease. It was the only one for which local anæsthesia was given. She died a few minutes after the operation had been completed. He did ligature in the first four cases, but he had now given that up in favour of partial thyroidectomy, removing one lobe and the isthmus and, if advisable, part of the second lobe. All rough handling and squeezing of the gland should be avoided. In one case crushing of the gland sent the pulse up to 180 per minute. For two days following the operation the patient should have large quantities of saline fluid. He only occasionally employed drainage. The cases which had been traced were either cured or very much better.

Mr. WALTER EDMUNDS said that in Dr. Dunhill's fourth class he placed cases of adenoma of the thyroid with some tremor, some staring of the eyes, and an easily excited heart. These should be regarded as undoubted cases of Graves's disease, as they have both its symptoms and its pathology; two cases were cited in which an adenoma was accompanied with all the symptoms including exophthalmos, and in which the symptoms completely disappeared on the removal of the tumour, and in which, under the microscope, the tumour showed the characteristic appearances. Besides this, ordinary cases of Graves's disease (Dr. Dunhill's Class 1) sometimes contain an adenoma showing the usual changes; a case in which such an adenoma, together with other portions of the goitre, was removed was referred to; the symptoms

[1] THE LANCET, Feb. 24th, 1912, p. 504.
[2] THE LANCET, March 9th, 1912, p. 641.
[3] THE LANCET, Feb. 17th, 1912, p. 422.

promptly disappeared. A series of 13 cases of Graves's disease treated with milk from thyroidless goats[4] and other ways, but without operation, was referred to. Ten of the cases became much better or completely cured, one remained about the same, and two died. It seems probable that some of the ten cases might have been operated on, and if they had been that they would have been better or well sooner. The case that was about the same might have been operated on, and if all had gone well would have been now better or well; but the most important question is about the two who died. They were both very severe cases, and it is very doubtful if there ever was a stage in either case in which they could or should have been operated on; in one there was unilateral exophthalmos nine years before the goitre appeared, and also an attack of unconsciousness followed by convulsions of one arm one year before the goitre; the goitre grew with great rapidity and a rapid pulse and œdema of feet soon followed. The other case was also very severe, and a bad prognosis was given early; a sister had previously died from the same disease. Neither of these cases could be regarded as simply hypersecretion of the thyroid to be treated by removing part of the gland, and hoping that the remainder would atrophy. The observation that after the removal of one lobe and part of the other the eye on the side of the only partly removed lobe is often more prominent is very important, as it seems to show that the disease is not due merely to an over-secretion circulating in the blood.

Dr. H. J. SCHARLIEB considered that the safety of chloroform and ether made it undesirable to use local analgesia for these cases, on account of their great nervousness and the liability to psychic shock. If a general anæsthetic were given he considered it absolutely necessary to give previously from 1/100th to 1/50th grain of atropine hypodermically—i.e., half an hour before the operation. The patient should assume a position of comfort and have time to get breath after being placed on the operating table. One should begin with a mixture of chloroform and ether, or chloroform and absolute alcohol. One could then change to open ether or chloroform, administered by any dosimetric method. The anæsthesia should be full for the first incision, being considerably lightened later, and deepened again for the final suturing.

Dr. G. A. H. BARTON did not consider that local analgesia had any advantages over general anæsthesia. He had notes of 33 consecutive cases, and they confirmed his view that these cases could be safely and satisfactorily managed under general anæsthesia. Having separated out his 33 cases into Dr. Dunhill's categories, he said that some blueness was noticed in only 5 and a tendency to respiratory failure in 1. Hypodermic injections preliminary to operation were not given in the first 14 cases, except 1/100th of a grain of atropine five minutes before the anæsthetic. In 8 cases there were minor difficulties from cough, and in 2 considerable hæmorrhage. In one case of obstructed airway he administered oxygen throughout. If scopolamine and morphia were given, followed by open ether, with or without oxygen, much less general anæsthetic was required.

Mr. RUPERT FARRANT pointed out that there was a definite cycle from thyroid excess to thyroid insufficiency. At the commencement of this circle hypothyroidism would be so slight as to be overlooked. It was impossible to say to what height hypothyroidism might rise before the stage of insufficiency commenced. His examination of a thousand lunatics showed that they had a cycle of thyroid changes, which ran parallel with the mental symptoms. In conclusion, he expressed the view that if hyperthyroidism were recognised from one to three years sooner than is usually the case Graves's disease would largely cease to exist.

Mr. HERBERT J. PATERSON contended that, no matter what anæsthetic were used, its administration in Graves's disease was always attended with considerable risk. Chloroform, even when given by a supposed dosimetric method, was very hazardous. If any general anæsthetic were given it should be open ether, preceded by morphia and atropine. He had seen six deaths directly after thyroid operations; probably there were more such immediate deaths from operations for this condition than for any other. Therefore it would be disastrous for anyone unskilled in anæsthetics to lightly give an anæsthetic. He did not agree with deepening the anæsthesia for the final suturing, as that prevented the oozing points being seized and tied before the wound was sewn up. He pointed out that the mortality from operations for exophthalmic goitre at the clinique of the Mayo brothers at Rochester, U.S.A., had been reduced to 3·9 per cent. The practice of the Mayos was to use X rays to the tumour for some weeks before operation, and during that time the patient was kept at absolute rest, and belladonna was administered. He (Mr. Paterson) always tried to have the patient in hospital for three or four weeks prior to operating, and carried out the preliminaries just mentioned, the rest being absolute. Having paid a high tribute to the surgical skill of Mr. James Berry in this operation, he expressed the opinion that if exophthalmos had been marked it never entirely disappeared.

Mr. H. M. PAGE related the experience, from an anæsthesia point of view, of 25 cases, many of which were those referred to by Mr. Donald Armour. In only one of the cases was there any real increase of pulsation at the end of the operation.

Mr. H. BETHAM ROBINSON said he had hoped to hear reference made to intravenous anæsthesia, and spoke of the apparent success of the intravenous administration of hedonal in a case of exophthalmic goitre, as shown by the comfort of the patient and the absence of engorgement at the surface of the cavity, as well as the fact that he did not have to ligature any vessel, and there was no trouble afterwards.

Mrs. DICKINSON BERRY commented upon the absence of light in the discussion as to how far general anæsthesia was an additional risk in these cases, even when taken well. She spoke of two cases, operated upon by different surgeons, chloroform being used in one case and ether in the other, in which the patients died within a comparatively few hours following the operation. She also spoke of the small amount of discomfort complained of by the patients after local analgesia.

The PRESIDENT spoke of the association of the condition of status lymphaticus with exophthalmic goitre in its relation to anæsthesia. It was generally agreed that the thymus coöperated in causing exophthalmic goitre, and there was reason to suppose that the size of the former gland might be some indication as to the severity of the lymphatism present. He had seen several of the operations done under local analgesia, and the strain of the injection, if it were thoroughly done, was sometimes described by the patient as being equal to that of the operation itself. There was no general verdict on the question of the anæsthetic in these cases among those whose operative experience was the widest. An objection to local analgesia seemed to be its prevention of venous oozing. In the worst cases of exophthalmic goitre even the slight degree of toxic effect produced by a general anæsthetic should be avoided.

Mr. JAMES BERRY, who was responsible for the debate being arranged, wound up the discussion in a general way. He said it was unnecessary for him to enter at full length upon his views and methods, as he did that about two years ago in the debate at the Hunterian Society. He had operated on the thyroid gland in over 670 cases, and of those only 11 were genuine Graves's disease, though he had often been asked to perform the operation in that disease in the acute stage, but had declined, on account of the risks being so great. Much yet remained to be done before operating on Graves's disease could be considered satisfactory. The idea that Graves's disease had only to be operated upon to be cured, though prevalent in some quarters, was to be deprecated, as it was a grave mistake. Owing to the kindness of registrars of various large London hospitals he had collected records of 97 cases in the last few years, all well-marked and typical examples of the disease. The results had been much the same at the various hospitals, except that at the Middlesex Hospital there were 10 cases reported without a death. The deaths in the 97 cases numbered 16, and of these 12 occurred within 48 hours of the operation, and most of them within 24 hours. In only 10 was local analgesia employed. In 55 the anæsthetic was chloroform, and in most of the others ether. Possibly the poor results were largely due to the operation not having been done early enough. On the other hand, under medical treatment the prognosis in early cases was by no means wholly bad. Many patients recovered completely under medical treatment. There was much uncertainty about prognosis in these cases. But, as Mr. Wilfred

[4] THE LANCET, Jan. 25th, 1908, p. 227; April 10th, 1909, p. 1040; April 23rd, 1910, p. 1135.

Trotter so well said, not only the mortality from the procedure should be taken into account, but the wretched and miserable condition of the patient also must have its weight. Operations for true Graves's disease must always be regarded as serious and even dangerous. He strongly urged that false cases, which were not Graves's disease at all, should be ruled out of statistics on the subject. In the operation he supported those who advocated gentle manipulation, scrupulous asepsis, and exact hæmostasis. There should also be considerable judgment as to how much of the gland to remove. In most cases he did hemi-thyroidectomy from choice. In very bad cases he inclined to ligature of one or both superior thyroid arteries at first. But death might follow even this simple operation. The administration of large quantities of fluid was, perhaps, the most important point in the after-treatment. He considered that chloroform, however skilfully administered, added materially to the risks of the operation. Those who operated for Graves's disease should not publish simply gross statistics, but lists of cases in which details were carefully given, including the condition of the patient before operation, and a considerable time afterwards. That would constitute the best guide for future operative policy.

SECTION OF BALNEOLOGY AND CLIMATOLOGY.

Spa Treatment of Neuritis.

A MEETING of this section was held on March 6th at 15, Cavendish-square, W., Mr. G. H. THOMPSON (Buxton), the President, being in the chair.

Mr. WILLIAM ARMSTRONG (Buxton) read a paper on the Spa Treatment of Neuritis. He emphasised the paramount necessity of definite diagnosis between neuritis, neuralgia, and fibrositis, as the successful prescription of spa treatment depended almost entirely on accuracy in this particular. He briefly indicated the points by which this could be done, and also the structural changes found in the nerve tissues in cases of neuritis. The various forms and stages were noted and the following general lines of treatment laid down: 1. The building up of general nerve health. 2. Rest—general, local, and physiological. 3. Avoidance of all violent and irritating methods of treatment. 4. Elimination of toxic products and correction of faulty metabolism. 5. The removal of nerve inflammation. 6. The improvement of nerve nutrition and the repair of nerve mischief The special spa methods recommended were: In acute neuritis applications of superheated air general or local, the Greville method being the safest and most effective. Hot packs of radio-active earths with or without ionisation. Cocaine ionisation with low strength currents, followed by light applications of the electric cautery over the tender nerve points, especially at the spinal nerve exits. Oxygen baths, which have a peculiarly soothing and tonic influence on the general nervous system. The drinking of the various natural waters to eliminate toxins. Massage and strong irritating electrical current are contra-indicated in the acute stage of the disease. In subacute and chronic cases the eliminating effect by kidneys, skin, and lungs of the radio-active waters such as Bath and Buxton, and through the bowels and liver of those of Harrogate, Llandrindod, and Strathpeffer is of notable value. The radio-active waters are also very helpful in the form of inhalation and baths, their efficacy being much increased by the addition of oxygen. Warm mineral baths with hot gentle *under water* douching are useful, preceded by the local application of dry superheated air or of very hot vaporised mineral water. Ionisation with cocaine, radio-active earth, or sodii salicyl., with or without the electric cautery application, is most valuable—as are Moor baths; and in the more chronic cases gentle application of electricity by means of the Schnee bath, wave static, or high-frequency currents. Hot massage baths on the Buxton, Aix, or Vichy systems may at this stage be employed with care and gentleness. The Plombières douche is indicated if the urine shows excess of aromatic sulphates. The researches of Lazarus, Saubermann, and others were mentioned in regard to the remarkable action of radium emanations in greatly increasing the output of uric acid by the kidneys, urea and butyric acid by the skin, and carbon dioxide by the lungs, while at the same time building up the vital forces, the use of these emanations being especially indicated in the class of case under discussion. Considerable stress was laid on the necessity in cases of obstinate neuritis of being on the look-out for pressure causes, especially from malignant growths and aneurysms.

The PRESIDENT said that it was necessary to differentiate neuritis from cases of painful but less serious forms of neuralgia, otherwise treatment suitable to the latter would produce results profoundly disappointing. The great essential in severe and early cases was rest, and it was often difficult to get the patient to concur, as he looked upon his visit to a spa as a sure and certain escape from such restraint. Mr. Armstrong had given the most approved and successful forms of treatment. Similar treatment of like conditions sometimes gave dissimilar results. In severe cases Mr. Thompson had good results with a 2 per cent. salicylate ionisation. In cases where blistering was used, he had found a dilute solution of formalin very effective in keeping open the part.

Mr. W. J. MIDELTON (Bournemouth) said he had employed the blister followed by savin ointment, and also a form of acupuncture, followed by the application of a mixture of croton oil, cantharides, acetic acid, and almond oil, in the treatment of neuritis, and quoted cases in which he had obtained marked success by one or other of these methods. He doubted if other methods were superior in any way to the above, and as the result of long experience he had succeeded in devising details by which practically all severe pain and discomfort wers eliminated.

Mr. E. SOLLY (Harrogate) said that in his experience many cases of so-called neuritis were primarily due to the condition now usually spoken of as "fibrositis," in which the symptoms were more manifest in the perineural tissue than in the fibrous tissues generally. In these cases treatment should be directed to the injured nerve tissue, and should consist of soothing treatment by rest and local application of heat; whereas in fibrositis affecting the coarser forms of fibrous tissue, forcible massage and stimulating forms of electric treatment were necessary.

Dr. LÉON BLANC (Aix-les-Bains) referred to the distinction between neurasthenic and neuritic pain. He said that as long ago as 1846 Baron D'Espin had pointed out that massage must not be used to the affected part. He advocated the use of the under-water douche after vapour baths, and considered that the radio-active mineral baths and packs were of the greatest value.

Dr. C. W. BUCKLEY (Buxton) laid stress on the necessity of distinguishing between parenchymatous neuritis and neuritis associated with fibrositis, which was very common. He pointed out that American observers had shown that many cases of so-called brachial neuritis were really affections of the subacromial bursa and not of the brachial nerves. He divided the treatment into three stages: in the first stage rest, with methods of inducing hyperæmia; in the second, hyperæmia again, with ionisation and mineral-water treatment; in the third, massage, ionisation with iodine, and hot douching.

Dr. WILLIAM EWART inquired whether the radio-active oxygen baths had led to any favourable results in the clinical behaviour of patients as regards their temperature and general metabolism. He also wished to know whether any good effect had been obtained from a mild systematic eliminant treatment in cases of a plethoric tendency.

MEDICAL SOCIETY OF LONDON.

X Rays in the Diagnosis of Hydronephrosis.—The X Ray Examination of the Urinary Tract.

A MEETING of this society was held on March 11th, Dr. J. MITCHELL BRUCE, the President, being in the chair.

Mr. J. W. THOMSON WALKER read a paper entitled "The Value of the X Rays in the Diagnosis of Hydronephrosis." The means of diagnosis of hydronephrosis and their practical value were shortly stated. Hydronephrosis presented two clinical stages, the first in which symptoms alone were present, and the second in which a swelling was found in the loin. The functional value of the kidney in the second stage was greatly impaired, and after relief of the obstruction the kidney did not return to its normal state. In the first stage there were two groups of cases. In one there was an obvious cause of hydronephrosis present (ureteric calculus, moveable kidney), in the other no such cause could be demonstrated (hydronephrosis due to valves,

stenosis, aberrant vessels). The symptoms of commencing dilatation in these groups were discussed and it was stated that they were variable and of little diagnostic value. Dilatation of the kidney was seldom diagnosed before a palpable tumour appeared in the loin. Exploratory operation was too serious a method for adoption in all cases. The X ray diagnosis consists in: (*a*) finding an increase in the shadow thrown by the kidney. In early dilatation special measurements must be made in a fixed position in order to recognise the enlargement. (*b*) Pyelography, which consisted in filling the pelvis of the kidney with an innocuous fluid opaque to the X rays (collargol) and obtaining a radiogram. The dilated pelvis was less sensitive to distension than the normal pelvis. Commencing dilatation was shown by clubbing and elongation of the calyces, and the pelvis became globular. The angle of union of the renal pelvis and ureter was shown by pyelography, and kinking could be demonstrated. The ureter, pelvis, and upper renal calyx should be in a straight or slightly curved line. The angle formed by the ureter, pelvis, and lower calyx should be wide. The position of the obstruction was shown by a stone shadow, a kink at the junction of the ureter and pelvis, or the shape of the collargol shadow. Illustrations were given of the value of pyelography in the diagnosis of commencing dilatation of the kidney in ureteric calculus, of persistent dilatation of the kidney after relief of obstruction, of the presence or absence of dilatation in moveable kidney and after nephropexy, of kinking of the uretero-pelvic junction, and in the demonstration of an actively contracting ureter in hydronephrosis due to moveable kidney, and in the diagnosis of hydronephrosis due to aberrant renal vessels.

Dr. W. IRONSIDE BRUCE read a paper entitled "The X Ray Examination of the Urinary Tract," which will later be published in THE LANCET.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Relation of Local Authorities to the National Insurance Act.

A MEETING of this society was held on March 8th, Professor A. BOSTOCK HILL, the President, occupying the chair.

Dr. A. K. CHALMERS opened a discussion upon the Relation of Local Authorities to the National Insurance Act. He stated that the sanitary legislation of the last century was concerned primarily with the removal of barriers against healthy living, which in ignorance of their effect had been allowed to grow up around large centres of population, but that during the past ten years inquiries had revealed how large was the sum of inefficiency in individuals which might be hidden beneath a too rigid insistence on the value of general averages, even though they pointed to a reducing prevalence of fatal disease and to an extended duration of life at its most productive ages. The National Insurance Act might be regarded as providing for a large part of the adult community a scrutiny similar in its character to that which was yielding hopeful results in the movement for the reduction of infant mortality and for the detection of disease among children of school ages. When considering the provisions of the Act which enabled county or county borough councils to share with the Treasury the payment of any deficit estimated as likely to arise in connexion with the administration of medical benefits, Dr. Chalmers expressed the opinion that in ordinary circumstances a deficit was not likely to arise. He spoke approvingly of the use of the word tuberculosis rather than phthisis in the Act if only for the reason that should the extension of sanatorium benefit to the families of insured persons become general preventive measures could be taken against consumption at a time when the lungs, if not entirely free from the disease, were at least free from phthisis in the sense that no open tuberculous lesions were present. He suggested that the extension of sanatorium benefits to dependents in reality simplified the problem for the local authorities who had not hitherto displayed any eagerness to provide for consumptives facilities for hospital treatment, mainly for the reason that they were not convinced that as an administrative weapon sanatorium treatment applied solely to the treatment of consumption could stand alone or as the dominant factor in the effort to reduce the prevalence of tuberculosis. Dr. Chalmers pointed out many difficulties surrounding the successful administration of Section 63 of the Act, which provides that a sanitary authority in whose area there may be shown to be excessive sickness due to the neglect of the authority shall pay out of its funds any extra expenditure alleged to have been incurred by the Insurance Committee as a consequence of the excess.

Mr. F. E. FREMANTLE deprecated the exclusion of the county councils and the sanitary authorities from direct participation in the administration of the Act. He considered that the scheme should be worked through the sanitary authorities with the county councils as intermediate authorities.

Dr. G. F. MCCLEARY attached great importance to the preventive side of the Act and could conceive circumstances in which Section 63 could be put in force with advantage, such, for example, as in the typhoid epidemic at Lincoln.

Dr. A. H. BYGOTT considered that the Act constituted a first line of defence against disease and that a second line could be provided by making more use of the Public Health Act of 1875 to provide institutional treatment.

Dr. E. W. HOPE pointed out that every Act of Parliament required for its administration knowledge and experience, both of which, however, could only be obtained in the case of the Insurance Act after it had been in force. He considered that sanatorium treatment must be regarded in the broadest manner, and that it was absurd to limit it to those cases which would come out as a success.

Dr. R. A. LYSTER said that those who were to control the Act were the insured, and that it was idle to talk to them of general measures of prevention. They would expect to have individual treatment. He hoped medical officers of health would not urge preventive measures too freely, for it could not be expected that these would produce as good results in the next few years as they had done in the past.

Mr. E. H. T. NASH emphasised the importance of dealing with pre-tubercular cases which were being gathered in by the school medical officer.

Mr. HERBERT JONES considered that Section 63 would have far-reaching effects if only as a lever to arouse into activity rural district councils. The section was justified by the large number of reports of medical inspectors of the Local Government Board in which sanitary authorities had been shown to be neglecting their duties.

The PRESIDENT, while agreeing that it was important to get hold of the pre-tubercular cases, feared that there would be many difficulties in doing so in rural districts, for local sanitary authorities had not yet had awakened in them the sanitary conscience.

LIVERPOOL MEDICAL INSTITUTION.

Calculi in the Ureter.—Diabetes Mellitus.

A MEETING of this society was held on March 7th, Mr. ROBERT JONES, the President, being in the chair.

Mr. W. THELWALL THOMAS read a short paper on the Diagnosis and Treatment of Calculi in the Ureter. He gave a tabulated analysis of 17 cases on which he had operated, and said the symptoms which were most marked were pain, hæmaturia, and pyuria. In all his cases pain had been present. In most cases there was aching pain often shooting into the testicle, sometimes unilateral, but not always felt on the side on which a calculus was found by the X rays. In 11 cases the pain had been intermittent and colicky. Hæmaturia was present in 10 of the cases, in some of these in very small amounts. Pyuria was present in about half the cases; in some along with hæmaturia. In 3 cases there had been neither hæmaturia nor pyuria. The most reliable indication was the presence of well-marked shadows on the radiogram in the line of the ureter, but even this was not absolute in the lower inch or so of the duct. In such cases the cystoscope helped. The ureteral bougie had been used, but it might pass beyond a stone and so lead to wrong conclusions. Mr. Thomas had not found any treatment of use that aimed at dissolving the calculi; large quantities of fluid might by washing the stone through the ureter lead to its expulsion. The stones had all been analysed by Professor B. Moore, and found to consist of insoluble salts of lime. Mr. Thomas had operated by the perineal and by the vaginal routes, but preferred and recommended the iliac route for all cases. With the patient in the

Trendelenburg position, an incision was made in the direction of the fibres of the external oblique over McBurney's point, the muscle was split and retracted, the internal oblique was also split and the peritoneum opened. It was possible by this method to reach the whole course of the ureter and even to excise the kidney. Dujardin's forceps for the bile passages had been found useful for the extraction of impacted stones, but hardly strong enough in their grip for some cases. A good head light was essential for this work. The ureter was opened on the anterior surface and the stones removed; the ureter was sutured with fine catgut, a drain was inserted, and the abdominal wall sutured in layers. Mr. Thomas showed lantern slides of the radiograms and of the steps in the operation.—In the discussion which followed Mr. F. T. PAUL said that division of the muscles had never given any trouble if the incision were well to the outside of the rectus muscle. He had found laryngeal forceps useful. He showed forceps which he had devised with a long flexible shaft and alligator jaws.—Mr. C. T. HOLLAND said it was impossible in some cases to be absolutely certain that shadows shown by radiograph were due to stone in the ureter. Calcareous glands were common in that region; also phleboliths were found at most all ages. The vermiform appendix and calcareous deposit in the fibrous tissues of the sacro-iliac joints might also give misleading shadows. He emphasised the need for a radiographic examination on the day of the operation as the stones moved and might disappear.

Dr. O. T. WILLIAMS and Dr. P. MILDRED POWELL gave the salient points of a long and elaborate paper on the Treatment of Diabetes Mellitus. Allusion was made to the work of Dr. Mathew Dobson, a physician of Liverpool, who, in 1775, was the first to demonstrate sugar by crystallising it out and obtaining alcohol by its fermentation. Dr. Williams briefly reviewed our knowledge of carbohydrate metabolism and the influence of ductless glands and the nervous system in relation to glycogenolysis. Charts were shown compiled from daily observations made for months by Dr. Powell on patients in the Royal Infirmary. In the study of the cases treated by diastase there was no obvious action on nitrogen or on carbohydrate metabolism, or on the organic acids. Throughout the whole series of cases there were small changes in reactivity of the urine to different indicators. Whether the diastase were given in liquid or solid form or in capsules insoluble in the stomach, the changes were not due to the ferment. The charts showed that the most successful cases had been treated by limited amounts of carbohydrate diet varying with the needs and idiosyncrasies of the patient; in some cases the urine had become sugar-free, body weight was gained and acidity diminished under a dietary where oatmeal was given up to 8 ounces per day. The recent discoveries of the effects of the removal of the cuticle of rice in producing beri-beri and the effect on the disease of giving the pericarp of the cereal suggested that there may be some part of the potato, of oats, and of rice which has a specific action on metabolism, and which, if it can be isolated from the cereals or from the preparations of diastase, may prove to have specific action in the treatment of this disease.—A discussion followed, in which Dr. C. J. MACALISTER, Dr. W. B. WARRINGTON, Dr. T. R. BRADSHAW, and Mr. T. H. BICKERTON took part. The last speaker mentioned that Dr. Mathew Dobson was not only a distinguished discoverer and physician, but was the first president of the Liverpool Medical Society.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Sloughing Bladder from Pressure of a Pelvic Myoma.—Cancer of Stomach simulating Ovarian Cyst.—Summer Diarrhœa in Infants.

A MEETING of this section was held on Feb. 16th, Mr. A. J. HORNE, the President, being in the chair.

Dr. H. JELLETT showed a post-mortem specimen of Sloughing Bladder due to Urethral Compression by Pelvic Myoma, consisting of the bladder, the uterus enlarged by a myoma, and the vagina. The patient, aged 40, suffered from acute retention of urine for a fortnight previous to admission to the Rotunda. A medical man had passed a catheter, and ordered this to be done twice daily. On admission the physical signs were: A hard tumour incorporated with the uterus, filling the pouch of Douglas, in front of which was the bladder reaching almost to the umbilicus. The urine was exceedingly dark and foul-smelling, contained blood, was alkaline; specific gravity, 1020. The bladder was washed out with a solution of permanganate of potash, and a permanent rubber catheter left in. The uterus was pushed out of the pelvis with difficulty. The patient gradually sank, and died the following day from septicæmia due to general poisoning from the bladder. Post-mortem examination showed great thickening of the bladder, and the mucous membrane had practically disappeared. The point of importance was that patients suffering from retention of urine should be submitted to pelvic examination.—Mr. H. B. GOULDING said that in a case recently observed the patient suddenly developed symptoms of being unable to pass urine. He recommended operation at once, and she was now quite well.—Sir W. J. SMYLY said that he had seen this case at the Rotunda in the absence of the Master, and it seemed to him exactly like a case of retroverted pregnant uterus. He referred to similar cases, but retention was not complete and there was no sloughing of the bladder.—Dr. A. P. BARRY and the PRESIDENT also discussed the case.—Dr. JELLETT, replying, said that death occurred in some cases from nephritis, but in this case apparently from general poisoning. Patients with myomata should be operated on while in good health without waiting for serious symptoms.

Dr. JELLETT showed a specimen of Cancer of the Stomach simulating Ovarian Cyst. The patient, aged 64, had six children, the last pregnancy being in 1888. She was admitted on Jan. 16th complaining of pain in the abdomen, which for six months had been getting larger. The uterus was small and atrophied, the abdomen containing a semi-cystic tumour about the size of a seven months pregnancy; there were some nodules in the right iliac fossa; no gastric symptoms were present. On opening the abdomen a swelling of the size of a football—tense and covered with large veins—was discovered. It was attached to the liver, and below it lay the transverse colon and small intestines. There was a firm adhesion between the abdominal wall and the tumour on the left side. A couple of hard nodular masses were to be felt to the right of the tumour in the region of the right kidney. She died about a week after the operation from heart failure. At the necropsy it was found that the tumour was a malignant growth originating in the stomach.—Dr. T. P. C. KIRKPATRICK said that in view of the fact that the patient had no gastric symptoms he might mention that this year he had heard of four such cases, in one of which practically the whole stomach was involved, yet the patient presented no gastric symptoms. It was well to remember that malignant disease of the stomach might reach an advanced stage without any signs of gastric trouble.—Dr. JELLETT, in replying, said that the tumour filled the whole abdomen, the liver being displaced and rotated.

Dr. J. SPENCER SHEILL read a paper on the Recent Epidemic of So-called Summer Diarrhœa amongst Infants, which was discussed by Dr. E. H. TWEEDY, Dr. KIRKPATRICK, Mr. J. S. ASHE, Dr. B. A. H. SOLOMONS, Dr. JELLETT, Mr. G. C. SNEYD, Dr. BARRY, Dr. ELLA WEBB, and the PRESIDENT.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on Feb. 23rd, Professor A. H. WHITE, the President, being in the chair.

Sir JOHN MOORE showed the Heart of a woman, aged 34, who was admitted to Meath Hospital on Jan. 12th last. Notes of the case showed that the area of cardiac dulness was much increased and the apex beat could not be made out. The pulse was small and scarcely collapsing in character. Systolic murmurs were heard both in the aortic area and at the apex of the heart, and at times a diastolic murmur under the sternum. An occasional doubling of the first sound and an inconstant presystolic murmur heard to the right of the left mamma further suggested mitral stenosis or some form of mitral obstruction. The average pulse-rate was 100 in the morning and 104 in the evening; respirations 31 in the morning and 34 in the evening. The diagnosis was combined aortic and mitral valve disease of rheumatic

origin. Death took place rather suddenly. On post-mortem examination the aorta was healthy. When opened and emptied of clots the heart weighed 29 oz.; there was a milk spot on the anterior surface of the right ventricle; the pericardium otherwise was normal. The walls of the left ventricle were greatly hypertrophied, and its cavity was dilated. Early fatty degeneration was shown by well-marked "thrush-breast" mottling of the musculi papillares. The right valves were normal. On the left side extensive acute vegetative endocarditis was found implanted on old fibrous disease of the mitral and aortic cusps, most exuberant on the anterior and right posterior segments of the aortic valve, and small crops sprouting from the orifices of the coronary arteries. The acute process had also spread from the mitral flaps to the inner surface of the dilated auricle. There must have been aortic insufficiency of old standing, and probably a little mitral regurgitation. The mitral orifice was not materially stretched.

Dr. WILLIAM BOXWELL read the clinical notes, and exhibited the heart and lungs, of a child of 8 years who was obviously in a serious condition when admitted suffering from pain and dyspnœa and showing the anxious expression and livid lips of pericardial effusion. He had never suffered from rheumatism or scarlet fever. He had been a particularly healthy child, well-grown and vigorous—facts of interest in view of the post-mortem findings. His present illness had been of a week's duration. Physical examination disclosed a marked increase of cardiac dulness, a loud shuffling friction sound, with a sharp thrill and a blowing systolic murmur. A pleural effusion was noted. Exploration with the hollow needle was without result. The child was *in extremis* and died next morning. At the necropsy a large sero-fibrinous effusion was found laterally and behind the heart. The mitral and aortic valves showed acute simple endocarditis. The right auricle was markedly dilated. There was a large patent foramen ovale with no attempt at valve formation. The tricuspid orifice was a mere hole, without any anterior cusp. To the right of this was a second orifice of the size of a child's thimble guarded by diminutive valve cusps and papillary muscles. Dr. Boxwell said he was more impressed than ever with the futility of the hollow needle for either exploration or treatment, and strongly advocated free incision and exploration with the finger of all cases of pericardial effusion requiring surgical interference.

In the absence of Dr. GEORGE PEACOCKE, Professor ALFRED SCOTT showed a specimen of Cancer of the Pancreas with Pancreatic Cyst from a woman, aged 39, but looking much older, who was admitted to Adelaide Hospital on Dec. 3rd, 1911. She had never been sick until about two months previously, when she began to suffer with flatulence, loss of appetite, and constipation. She noticed a lump in her abdomen on the left side, which, though not tender, caused a dull aching pain. She had not vomited. On Dec. 1st she noticed that she was jaundiced. She did not notice much loss in weight. On admission she was deeply jaundiced. The urine contained bile and the stools were light in colour. Her thoracic organs appeared normal. Examination revealed a large tumour, occupying chiefly the left side of the abdomen, coming from under the costal margin on the left side, extending below the umbilicus, its inner margin being felt slightly to the right of the middle line. The edge of the liver could be made out separate from the tumour, which was dull on percussion, did not move on respiration, and was not tender on palpation. Until a few days before death vomiting was only occasional, and was never a marked symptom. The patient died on Jan. 26th. The specimen showed the surface of the liver covered with numerous nodules, having the dimpled and typical appearance of secondary growths. The tumour contained a vast quantity of fluid and a number of cells in a state of fatty degeneration. The fluid had a trivial action on starch and protein, but there was nothing remarkable in it. The cyst had cavities and there was moderately dense connective tissue. Lower down was a very mottled greenish-white mass, which sections showed to be a small round-celled cancer.

Professor SCOTT also exhibited for Dr. Peacocke a specimen of Miliary Cancer of the Peritoneum in a woman, aged 47, admitted to the Adelaide Hospital on Feb. 8th, who had enjoyed excellent health up to two months previously. On admission she was very ill—marked dyspnœa, cyanosis, and an almost imperceptible pulse. Fifteen ounces of bloody serum were withdrawn from the chest, with slight relief, but she died on Feb. 10th. Post mortem the right and left side of the pleura, as well as the abdomen, were filled with fluid, the lung collapsed, and all tissues very much matted. The mesentery was thick and covered with little growths, which had the appearance of either tubercle or cancer. The liver was adherent to the diaphragm, but there were some little white growths on the surface. All over the peritoneum there were miliary growths. Sections of the liver showed it to be carcinoma. The starting point could not be traced as there appeared to be no focus. No explanation could be found for the onset of the disease.—The cases were discussed by Dr. J. A. MATSON, Dr. R. J. ROWLETTE, Mr. W. I. DE C. WHEELER, Dr. W. D. O'KELLY, the PRESIDENT, and Mr. K. E. L. G. GUNN.—Professor SCOTT, replying, said with regard to the first specimen the urine contained nothing except bile. Cammidge's reaction was not done. With regard to the second case the ovaries appeared to be normal.

Mr. WHEELER showed a specimen of Abdominal Aneurysm from a man on whom he operated some months ago. The patient, after the introduction of 150 inches of wire and the performance of a gastro-enterostomy, developed intestinal obstruction. The abdomen was again opened, and a loop of jejunum was found compressed between the tumour formed by the aneurysm and the stomach and abdominal wall. The obstruction was relieved, but the patient died in a week from rupture of the aneurysm at a point remote from where the wire was introduced. The wisp of wire (Colt's) was found situated between the layers of laminated clot (formed before operation), and had not expanded to any extent. Mr. Wheeler considered that the lesson to be learned from this information was not to introduce the wire until there was a free flow of blood through the cannula in order to be certain that the wire would enter the lumen of the aneurysm and not be pushed between layers of clot. If necessary two or three punctures should be made before pushing the wire home. The two cases operated upon previously by Mr. Wheeler were alive and well—17 and 8 months respectively after operation. Mr. Wheeler also showed four specimens of Stomach Cancer removed by operation.—Dr. ADRIAN STOKES and Mr. GUNN discussed the cases, and Mr. WHEELER, in reply, said that the stretching of the peritoneum in pancreatic cyst and hydronephrosis was not accompanied by pain, but where there was marked pulsation it appeared to him that the stretching plus the pulsation might cause it. The great pain was not of necessity due to the erosion of the vertebræ.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 1st, Mr. H. Littlewood, the President, being in the chair.—Dr. J. B. Hellier read a paper on Vesicular Mole—Benign and Malignant. This was illustrated by lantern slides and by an excellent series of microscopic sections arranged by Dr. M. J. Stewart, and by micro-photographs kindly lent by Dr. J. H. Teacher of Glasgow. Dr. Hellier dealt chiefly with the clinical features of the conditions under consideration. He mentioned two cases where excessive vomiting in pregnancy had been due to vesicular mole. He dwelt on the great difficulty sometimes experienced in the early diagnosis of the malignant from the benign form, showing that the proliferation of the trophoblastic layer in the two forms respectively was one of degree rather than kind. He spoke also of the occasional retrogression and healing of choric-epithelioma.—Dr. Stewart read a short paper on the Pathological Questions most under Discussion at Present in Regard to Chorio-epithelioma.—Mr. Walter Thompson described a case on which he had recently operated successfully for Chorio-epithelioma following vesicular mole.—Dr. T. Churton showed a child, aged 3 years, with Obliteration of the Hepatic Veins which produced rapidly recurring Ascites. This was finally treated by incision, and recovery occurred with dilatation of the superficial abdominal veins.—Mr. J. F. Dobson showed a Gall-stone removed from the Ileum, where it had produced acute intestinal obstruction, and also Gall-bladders which had been in fistulous communication with (*a*) the colon and (*b*) the duodenum.—Mr. A. L. Whitehead showed a case of Tuberculous Iritis.—Mr. Michael A. Teale showed two sisters showing Congenital Dislocation of the Lens of Each Eye.—

Other cases and specimens were shown by Mr. H. Secker Walker, Mr. Thompson, Mr. E. W. Bain, Dr. R. A. Veale, Mr. R. Lawford Knaggs, Dr. W. H. Maxwell Telling, Dr. G. W. Watson, Mr. H. Littlewood, and Dr. L. A. Rowden.

At the previous meeting of the society, on Feb. 16th, Dr. Myer Coplans read a paper entitled "Some Gleanings from Leeds Markets," which was by inadvertence not referred to in the report published in THE LANCET. He said: With the advent of the Insurance Act a new condition arises whereby all care for the sick workers is placed directly in the keeping of the medical practitioners of this country, and there follows the natural corollary that there will arise in preventive medicine a new movement for the extension of its domains and over-lordship, one having for its principal exponents and votaries all who are like to be harassed and unjustly penalised for every infraction of the canons of sanitation, be the offender the individual or the community. The new Health Committees in their anxiety for the maintenance of public health are like to regard the behaviour of the sanitary committees of the local authorities with the proverbial care, attention, and watchfulness of the cat towards a mouse. Many problems await solution, one of them that of a pure food-supply; and inasmuch as a considerable proportion of the food consumed by the workers of Leeds passes through the Leeds markets some gleanings of the immediate condition of affairs may not be untimely. For food totally unfit for human consumption the Legislature has already provided drastic measures. Still, there remains a wide and extensive borderland to which the terms tainted, degraded, and unwholesome are the only just qualifications. The sale of such food is free and unrestrained. Not one of us would permit its use for the sustenance of a sick man, yet we are all cognisant of the elementary and compelling consideration that its consumption will undermine the healthy; and the pity of it all is that the poor and ignorant of this country do, for some reason, harbour the belief that the mere fact of exposure of food for sale in a public place is of itself a sufficient guarantee of wholesomeness. With the modern development of quick transit and cold storage we have reached a carnival of misdescription and fraud. Take a walk through the markets at noon, day by day, for a week, and watch the fish, the poultry, the game, and the meat in particular. The fish has lost its freshness; the frequently invoked hose-pipe has washed away all its scales and odours, and withal an appropriate dab from a kindly-placed bowl of ox-blood gives semblance to a recently departed life. That "filleted haddock" yonder is dogfish or catfish, or cod or ling dyed yellow, and the "finney" haddock was smoked in London; true enough, there is some haddock, buff-dyed, on sale, but it is to be found in the cheap tins labelled "salmon." The baskets and boxes of dressed rabbits will interest you; the former, 5 per cent. of the total, contain locally trapped animals—the latter, foreign and colonial produce, have undergone cold storage and are but recently thawed. Yet all are unblushingly described as Yorkshire trapped rabbits, and it is obvious that with many some degree of putrefaction had preceded the cold storage. Yet follow their market history. The boxes are opened on Tuesday and the market price is 10*d*. On Wednesday they are skinned and the price is 9*d*. On Thursday it is 8*d*. and 7*d*. The flesh and the parietal fat are alike changing colour, and all the while they are being exposed to the dust and dirt of the market ways. On Friday the parietal fat is stripped and the price is 6*d*. The carcass is now appreciably smaller in size and strips of decayed flesh have been removed. Last scene of all is late Saturday night; the price is reduced to 4*d*. Clearance is imperative and the buyer must be tempted, for evidently cold storage is too expensive. At this late hour fish, which earlier in the week was sold at 3*d*. per pound and upwards, is now retailed at 5 pounds for 2*d*., and the stall-holder does not hesitate to express the private view that the food is unfit for his own dog, and that people who buy food at such prices deserve all the ills they suffer. Many of the stall-holders possess branch shops in the town, and to the market at this late hour returns all unsold material; nor does the yellow glare of the stall lamps facilitate any too nice distinction in the various flesh tints. Of the meat and poultry, the less said the better; in and out of the refrigerator they go after exposure to the market dirt, and when during the all-busy Saturday night they arrive once again on the stalls the salesman is ever-ready with his assurance of freshness of condition, knowing full well that putrefaction has simply been stayed and all keeping qualities have departed. About Christmas time you will see old dates and figs undergoing a curious washing process, immediately afterwards to appear on the stalls as "newly arrived" fruit at bargain prices, and on Boxing Day you may witness the sight of unsold turkeys being prepared for their second and perhaps third annual arctic sojourn in the local "frig." Everywhere you may purchase in their dyed skins dyed sausage meat made up of the scrapings of stale meat or perhaps worse. I cannot find evidence either at Leeds or elsewhere that systematic steps are taken to determine the presence of tuberculosis or other communicable disease in this form of food. The retail druggist is equally ready to sell, without let or hindrance, "sausage-dye" or "milk-colouring," or "egg-yolk dye," and the cheap pastry stalls with cakes of wondrous yellow tint are only outdone by the rainbow hues of the sweatmeat trays. Sophistry everywhere. The Jewish butchers serving a community of 25,000 souls do, by ritual law, declare about one-tenth of the animals slaughtered by them to be unfit for human food, yet a standing arrangement exists whereby the carcasses are disposed of whole to non-Jewish butchers. Let us hope the time is not far distant when every butcher will be compelled to provide, on his own premises, ample refrigerator accommodation; when meat and like foodstuffs will not be permitted to be exposed to the dirt and dust of highways; when large public refrigerators will not be permitted to be utilised as a refuge for those destitute of all moral compunction in their desire to store or hide putrid, decayed, unwholesome and degraded foodstuffs.—Mr. Littlewood, Professor A. S. F. Grünbaum, Dr. R. Veitch Clark, Dr. J. Eddison, and Dr. J. Allan took part in the subsequent discussion.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 29th, Dr. H. Ernest Knight, the President, being in the chair.—Mr. E. F. Finch opened a discussion on the Treatment of Fractures and their Results. His remarks were summarised from the examination of 200 cases of fracture of the long bones which had been treated at the Sheffield Royal Infirmary during the five years 1906 to 1910. He summed up the treatment shortly as (1) preventing further deformity; (2) "setting" the broken bone; and (3) fixing the parts at rest. The "setting" must be done by manipulation, with or without operation. It should be more often controlled by the skiagraph. X rays should be used more often in making a diagnosis, particularly in injuries in the neighbourhood of joints and in the carpus and tarsus. Splints, using the word in the broadest sense, must be employed to keep the parts at rest. The functional result is more important than the anatomical. So the lines of strain and movements required must be kept in view rather than the anatomy. One must endeavour, if possible, to anticipate disabilities likely to occur after the injury and to preserve the alignment of the bone. This latter point is of importance in the prevention of traumatic osteo-arthritis, which condition was present in 18 per cent. of the cases. He was of opinion that all fractures of the vault of the skull should be operated on. He considered fractures of the long bones under two heads: (1) those in the neighbourhood of joints; and (2) those of the shaft. In the neighbourhood of the shoulder-joint the treatment should be either by axillary pad or by extension with full abduction of the arm; in the elbow-joint region the forearm should be first supinated and then flexed fully. Passive movement should be delayed for two weeks. Active movement can be allowed after the fifth day. Fractures of the shaft of the humerus are best treated by a double wedge splint. Colles's fracture should always be disimpacted either by manipulation, wrench, or operation. The treatment of fracture of the femur up to 14 years, judging by results, is satisfactory. After this age the question of operation should be seriously considered. Fractures in the neighbourhood of the hip-joint are more common than supposed, giving rise to various degrees of coxa vara. In the neighbourhood of the knee-joint the results following treatment by extension are the best. Spiral fractures of the tibia must be operated on to get good results. In a Pott's fracture the backward displacement must be especially corrected. Details as to the average time in hospital and off work were given.—Mr. F. A. Hadley alluded to the danger of disasters occurring due entirely to the method of treatment, when cases had to be dealt with under unfavourable circumstances, as at

distances in the country. Irretrievable damage might occur to a limb in less than 24 hours which had been put up in complete flexion. Under such conditions some of the older methods were the safest. In operative cases he referred to the difficulty the surgeon often encountered after reaching the bone, in doing anything useful. The greatest value of open operation lay in the removal of bone fragments and blood clot from the soft tissues. Very often simple suturing of the periosteum was all that was required. Plates so often had to be removed that he preferred to do without them unless they were absolutely necessary. The reason that osteotomy was so successful was that the fracture was made whilst the muscles were relaxed.—Dr. D. Gray Newton showed a new truss for moveable kidney. It is designed and made on the cross action principle. The body spring exerts a pressure upwards, backwards, and slightly inwards. The front pad is made of thin metal plates connected by springs. The back pad lies on the opposite side of the body at a higher level, and consists of a thin metal plate to which a ball-and-socket joint mount is attached.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the dispensary on March 7th, Mr. T. H. Ionides, the President, being in the chair.—The following cases, &c., were shown. Mr. H. H. Taylor: Two men on whom he had performed Tre. phining of the Sclera for Glaucoma, with satisfactory results. —Mr. G. Morgan: A girl, 6 years of age, who showed a Great Enlargement of the External Malleolus of the Right Fibula. Shortly after birth it was noticed that the right fibula at its lower end was larger than the left, but this had not been seen to make any progress till about six months ago. The swelling was not painful or tender, and there was no sense of yielding on pressure. The X rays showed a complete hypertrophy of the whole malleolus, and not an overgrowth of any one part, as in an exostosis. The general opinion was that an exploratory incision should be made to ascertain its nature.—Mr. A. G. Bate: A Uterus removed for Inveterate Prolapse. The interest of the specimen centred round the fact that 15 years ago a double oöphorectomy had been performed for fibroid growth. The organ showed a complete atrophy of the fibroid tissue.—Mr. H. G. Mallam: A Parenchymatous Goitre in a man of 60, which had commenced at about 40 years of age, had gradually increased till five years ago, since when it had remained stationary. It was not causing any symptoms. The treatment had consisted in the administration of thyroid extract and painting with iodine, with no result.—Dr. C. F. Bailey read a paper on Stereoscopic Radiography, which was illustrated by photographs and lantern slides of various bone and visceral lesions.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 1st in the rooms of the Post-Graduate College of the West London Hospital, Mr. W. McAdam Eccles, the President, being in the chair.—Clinical cases were shown by the President and Mr. N. Bishop Harman.—At the commencement of the proceedings the President referred to the death of Lord Lister. Their society had a particular interest in recording the greatness of the work of the man who had gone from amongst them, for he was one of their members. A motion to convey the expression of the meeting to the relatives of Lord Lister was proposed by the President, the members standing to signify their agreement.—Mr. F. L. Provis read a paper entitled "Pain in Women in the Iliac Region and in its Immediate Neighbourhood." He classified the causes of such symptoms as arising from: (1) Certain general disorders; (2) disorders of the nervous system; (3) from abdominal disorders; (4) disorders of the generative organs. The range of the causes of this symptom necessitated a limitation of their review, and he proposed to limit it to the last group. Displacement of the uterus was the most common cause. Palliative measures failed to relieve these cases; surgical treatment was necessary so as to prevent involvement of the appendages. Ventrifixation he thought the best operation. Dysmenorrhœa other than spasmodic was either congestive or inflammatory. Referred pain to the ilium was common. Frequently no alteration of the ovary could be found except tenderness; in such cases there was probably an ovaritis or ovarian neuralgia. It was a neurosis or neurasthenic condition. The fact that in many a slight enlargement of the Fallopian tube could be made out pointed to a possibly inflammatory origin; cases should be treated as such. In a very few cases only was removal of the ovary justifiable. He next considered alterations in the position and relations of the broad ligaments whereby they tended to obstruct the entrance of the pelvis, or became adherent to the gut and obstructed the passage of fæces. It was a true proptosis, and he considered it of fairly frequent occurrence. It necessitated operative interference with subsequent abdominal massage.—The President said that pain in the iliac region was so common that all of them, whatever their particular range of work, would be grateful for the paper of Mr. Provis. It should not be forgotten that it occasionally was found in middle-aged stout males as an indication of digestive troubles. In young women it was not infrequently seen with spinal curvature; the patient often significantly placed the fingers of the hand over the right iliac fossa and the thumb towards the right sacro-iliac synchondrosis. In these cases he thought the scoliosis secondary to some pelvic trouble.—Dr. J. A. Mansell Moullin said the particular conditions spoken of by Mr. Provis were well known and capable of exact diagnosis. The difficulty began when none of these conditions was present. Yet the patient might be a confirmed sufferer, her life rendered almost intolerable by constant aching pain, and they wanted to know the cause of it. He had little doubt that pain was ovarian; it only occurred during reproductive life. He considered it possibly due to the development, growth, and enlargement of the Graafian follicle and its final rupture—pain analogous to that associated with the eruption of a tooth.—Mr. Rickard W. Lloyd and Mr. Herbert W. Chambers joined in the discussion, and Mr. Provis replied.

Reviews and Notices of Books.

The Mechanism of the Heart Beat, with Especial Reference to its Clinical Pathology. By THOMAS LEWIS, M.D. Lond., M.R.C.P. Lond., D Sc., Lecturer in Cardiac Pathology, University College Hospital Medical School; Physician to Out-patients, City of London Hospital for Diseases of the Chest. With 5 Plates. London: Shaw and Sons. 1911. Pp. 295. Price 16*s.* 6*d.*

THIS important monograph, which while containing much new work affords also a review of the most important recent observations upon the cycle of the heart's action in health and disease, is a valuable contribution to cardiac physiology and pathology. Dr. Lewis wisely starts from the beginning and does not assume a knowledge of the methods of investigation on the part of his readers. Although the matters of which he treats are not infrequently complex and involved, and the analysis of some of the records shown is intricate, he writes of them clearly and simply, and explains as he proceeds. The observations upon which the book is based comprise a large number of clinical records and experimental studies. Dr. Lewis has endeavoured to elucidate the abnormal actions of the heart in disease by comparison with similar disturbances artificially produced under experimental conditions. The conclusions arrived at and the suggestions offered in explanation of the commoner forms of cardiac irregularity are based upon graphic records, chiefly polygraphic and electro-cardiographic tracings, with which the book is copiously illustrated. In the preface a high meed of praise is accorded to the results of the graphic method in the investigation of cardiac conditions.

The book opens with a short but clear and well-illustrated account of the recent anatomical discoveries in connexion with the heart. The sino-auricular node and the junctional or conducting tissues with their relations to the network of Purkinje are described, and the current views as to their functions are stated. Intra-auricular pressure curves are discussed and compared with the venous records obtained by the Mackenzie polygraph. This instrument is described and the forms of the normal tracings obtained by its use figured and analysed. The various positive and negative

waves are indicated by the letters a, x, c, x′, v, and y. The incidents occurring in the cardiac cycle simultaneously with each of them are discussed in relation to the production of these waves. Einthoven's string galvanometer is then described, and its application to the record of the heart's cycle is fully explained. The forms of curve obtained with different leads from the body are illustrated, and the variations in the curves are referred to the corresponding occurrences in the cardiac cycle. An interesting chapter is devoted to the presentation of new evidence that the "pacemaker" of the mammalian heart is localised in the immediate neighbourhood of the sino-auricular node. The methods of analysis of arterial pulse curves, of polygraphic and electro-cardiographic records are then described in detail. The production of heart-block experimentally in the mammal forms the subject of a chapter introductory to a full discussion of heart-block as observed clinically. The occurrence of heart-block as a result of experimental interference with the auriculo-ventricular bundle is established by reference to the work of Erlanger, and Cohn and Trendelenburg. In connexion with heart-block in man, the clinical signs and the tracings obtained are reviewed, and then the post-mortem findings in the recorded cases are tabulated and discussed. The conclusions arrived at are that auriculo-ventricular heart-block, as it has been observed clinically, has been due in the great majority of cases, if not in all, to structural alteration in the auriculo-ventricular bundle, and that digitalis and vagal heart-block have been usually the outcome of the action of the drug or the nerve upon tissues already deficient in the power of conduction.

In classifying and analysing other disturbances of the cardiac rhythm Dr. Lewis finds that the five cardiac functions of rhythmicity, excitability, contractility, conductivity, and tonicity, which have been used by many other writers as the basis of classification, are not satisfactory for that purpose. He therefore substitutes a scheme by which the beats observed are divided into two classes—homogenetic and heterogenetic, the former being of spontaneous origin in areas of muscle unaffected by extraneous impulses, the latter being exclusively of pathological character and presenting well-defined time relations, differentiating them from normal beats. The so-called idio-ventricular rhythm is given as an example of a homogenetic rhythm, certain premature ventricular beats, or "extra systoles," as instances of heterogenetic contractions.

The characters of heterogenetic contractions originating in various parts of the heart are then described, and the methods by which they can be referred to their source of origin are explained. Various heterogenetic rhythms of ventricular and auricular origin are then discussed, and examples are given both of experimental and clinical varieties of each. Upon the basis of these observations the obscure condition of paroxysmal tachycardia is analysed. A classification of tachycardias in general is given, homogenetic and heterogenetic varieties being separated. The latter are subdivided, various grades being separated, according to the situation of origin of the ectopic rhythm up to the extreme form of auricular fibrillation. The evidence upon which the conception of auricular fibrillation is based is then presented. Its occurrence as a clinical entity, both in man and the horse, is established, and its application to the explanation of cases of complete and permanent irregularity is discussed in an exhaustive and interesting fashion. Other conditions examined in connexion with the heart beat are bigeminy, the vagus, the Adams-Stokes syndrome, and alternation.

Dr. Lewis dedicates his book to James Mackenzie and Willem Einthoven, and expresses his indebtedness to the Beit Memorial Research Fund for the leisure in which to write. His book constitutes an important addition to our knowledge of the cardiac action, and we have read it with great interest.

Prevention of Disease and Inefficiency, with special reference to Indian Frontier Warfare. By Lieutenant-Colonel PATRICK HEHIR, I.M.S. Second edition. Allahabad: Pioneer Press. 1911. Pp. 656.

THIS volume is a full and comprehensive treatise on hygiene and preventive medicine as applied to India, and especially with reference to military conditions and requirements. After an introduction dealing with elementary notions as to the physical geography and climate of the country, and the importance of health preservation from the public service point of view, the author deals in Part I. with the physical training and development of the soldier; in Part II. water-supply, air and ventilation, food and dieting, the construction and sanitation of barracks, and the proper management of camps and cantonments are considered; Part III. treats of personal hygiene; and in Part IV. the prevention of disease in peace and war, and the causation and prevention of the principal tropical diseases individually are somewhat fully discussed. Parts V. and VI. deal shortly with statistics and Indian frontier sanitation in warfare. It is seen that the scope of the work is considerably more extensive than its title would lead one to expect. It is a manual of hygiene with special reference to Indian conditions, as to which Lieutenant-Colonel Hehir's experience and previous published work entitle him to speak with authority.

In regard to acclimatisation, the author alludes to the European soldier as being transferred suddenly from the United Kingdom, with an average temperature of 51° F., to India, with an average of 82°. The "average" temperature for these islands has some hygienic significance, but one might as well speak of the average temperature of Europe as of that of India; even the word "climate" is used by Mr. H. F. Blanford in the plural when applied to India; still less can any idea be attached to "average temperature" when referring to such a vast and varied extent of the earth's surface. The advice given as to the mode of life and precautions to be taken for the preservation of health is excellent. The description of water-supplies and of the risks to which they are exposed is also comprehensive and judicious. As to the examination of water, perhaps more importance is attached to chemical analysis than would now be generally admitted, but the bacteriological examination is so delicate in its technique as to be almost impossible of attainment under ordinary conditions of military service in India. As to filtration, it is said that there is little to choose between the Chamberland and Berkefeld forms. If arrest of germs is the object sought for, there is a good deal of difference between them, as the work during recent years of Bulloch and others has shown; whether either of these, or any other bougie form, is suitable for ordinary Indian use is a matter of doubt; the closest and most constant supervision is necessary. Colonel Hehir does not mention the recent work of Haldane and others on ventilation, and still considers carbon dioxide and organic effluvia to be the chief harmful factors. It is the temperature and the humidity that are now recognised as being more important.

The subject of food and dieting is comprehensively treated, the author being acquainted with most of the varied conditions obtaining in India. In regard to British troops, he makes the excellent recommendation that their principal meal should be served in the evening, a light lunch only being taken in the middle of the day. This has been suggested before, but a deeply rooted conservatism has hitherto resisted any change; in time it will probably come about (note that the old-fashioned heavy "tiffin" has now been generally given up), and people

will wonder why it was not done before; as the author says, "from a physiological and hygienic standpoint the change has all in its favour." Colonel Hehir is very temperate in dealing with the alcohol question; abstinence is to be encouraged, but the men are not to be coerced into *total* abstinence. The detailed information as to sanitation of barracks, camps, and cantonments is very useful. The author has done excellent service in gathering together and clearly setting down the experience of old residents in the tropics for the benefit of military and civil officers newly arrived in the country. "At the risk of being considered old-fashioned," he strongly recommends the so-called cholera belt as an indispensable article of kit, though "many British officers consider it a fad." A full account is given of the necessary measures in all the important preventable diseases that occur in India, Malta fever and sandfly fever not being overlooked. In the concluding pages some points of organisation in regard to frontier campaigns are dealt with, and a few statistical data as to disease prevalence in such warfare are detailed; in the next edition the author might usefully enlarge on this part of his subject.

We have indicated the scope of Colonel Hehir's treatise, which will be of great use to all medical men in India. The Commander-in-Chief (to whom the book is dedicated) contributes a short preface, and refers to the increasing interest in disease prevention that has been awakened in India during recent years. Sir O'Moore Creagh is known himself to be well acquainted with military sanitary arrangements; his commendation of the present work will doubtless lead to a wider diffusion of knowledge on the subject throughout the country.

Annual Report of the Proceedings of the Diseases of Animals Acts of the Board of Agriculture and Fisheries for the Year 1910. London: Wyman and Sons.

THIS brochure embodies the report of the Chief Veterinary Officer of the Board of Agriculture, Mr. S. Stockman, M.R.C.V.S., and the Assistant Secretary of the Animals' Division, Mr. A. W. Anstruther, and is particularly interesting this year because of the recent foot and mouth outbreaks amongst cattle. The Board, and especially the Veterinary Department, deserve great credit for the success which has attended their recent efforts against this highly contagious disease which periodically devastates the herds of cattle in certain European countries, and which once played such havoc and caused such loss amongst the dairy cows of Great Britain. The "stamping-out" method may be drastic, but it is undoubtedly effective, and for a country like Great Britain, which is surrounded by water, there is no doubt that it is the best prophylactic measure to adopt.

At the laboratory 3782 specimens were received and were reported upon from animals which were suspected of swine fever, anthrax, sheep-scab, glanders, rabies, epizootic lymphangitis, and pleuro-pneumonia. It is gratifying to note that in none of the specimens suspected of the three latter diseases was the diagnosis confirmed, and so England is still free of these scourges. Experiments are being continued upon epizootic abortion of cattle. A new variety of trypanosome has been discovered, the first to be reported in British cattle which have never been out of this country. The hypoderma bovis and its pupa stage (the warble), also sundry varieties of ticks found on sheep and cattle, have been the subject of a series of observations of great interest to medical entomology, and the notes are worth perusal by scientists engaged in like pursuit. Sixteen valuable pedigree cattle were immunised against red-water before being shipped to the colonies, a new departure, for the carrying out of which Mr. Stockman's experience in the Transvaal, before he became chief of the veterinary staff of the Board of Agriculture, renders him particularly fitted.

The Assistant Secretary of the Board, Mr. Anstruther, in the portion of the report which emanates from his pen, deals ably with the rules and regulations which have been so effectually carried out by his staff, and the two sections (the veterinary and the lay inspectors) have worked loyally together.

In its many-sided capacities, and dealing, as it of necessity does, with all classes of animal, the officers of the department have their hands very full, and the tabular statistics at the end of the report give ample evidence of the enormous mass of work which comes under their control. There is no country in the world where the work is carried out in a better fashion, and by the presence of an efficient department of this kind the agricultural community is saved many hundreds of thousands of pounds annually.

Meine Präparationsmethode des Operationsfeldes mittels Iodtinktur. Von Kgl. Rat Dr. ANTONIO GROSSICH, Primarchirurg am Ospidale civico in Fiume. Berlin and Vienna: Urban and Schwarzenberg. 1911. Pp. 80. Price 3 marks.

THE employment of a solution of iodine was introduced in the spring of the year 1907 by Dr. Grossich, who in this volume gives a full account of his method. It is too often believed that the use of solutions of iodine in surgery is recent. Several surgeons, however, used iodine in various ways in surgery at least as long ago as 1880, but it is certain that the publication by Dr. Grossich of his use of iodine has led to a very wide employment of it all over the world. This volume contains an account of the mode of using iodine in wounds, in aseptic operations, and in septic operations, and the results obtained are described. The author discusses the various harmful complications that have been said to follow its use, and shows that for the most part no harmful effects occur. It is important for the reader of this book to bear in mind that the tincture of iodine employed by Dr. Grossich is a 10 per cent. solution, and that it is four times as strong as the tincture of the British Pharmacopœia. The author, of course, lays great stress on the importance of not washing the skin before the iodine is applied. The volume contains also reprints of three papers already published by the author on the subject, and he gives abstracts of a large number of the articles written by other surgeons on the same subject. These abstracts occupy more than half the book.

The Significance of Existence. By I. HARRIS, M.D. Koenigsberg. London: Longmans, Green, and Co. 1911. Pp. 324. Price 6*s.* net.

IN his preface Dr. Harris almost disarms criticism by saying "much in this book is incomplete, and some of its statements are sure to call forth criticism"; but should the critic ask why, then, was the book written? he is answered in the next sentence, "I hope that the general conclusions arrived at will not thereby materially suffer." The first chapter is entitled "Infinite and Finite" and its obscurities are seen to depend on the author's puzzling interpretation of the meaning of words. For instance, on p. 26 we read, "Finite and infinite do not exclude each other, they do not possess antagonistic characteristics, but their relation to each other is really corresponding to that subsisting between the adjective round and the noun blue." On p. 28 are two conclusions which materially suffer from the same cause. The following are the quotations: "We must conclude, therefore, that existence possesses the following attributes, eternity, infinity, and causelessness. But in the same existence *finity* (*sic*) must

be included"; and "we conclude, then, that finity stands in the same relation to infinity as eternity stands to infinity—namely, that they are attributes of existence in exactly the same sense." A printer's error on p. 47, "a thousandth of which compose an atom of hydrogen," makes one hope that the obscurity of the quoted sentences may in part be due to printers' errors; but whatever words are substituted, the meaning in many places eludes the reader. On p. 289 it is stated that "the very essence of harmony is to produce an alternate state of activity and repose." Why of harmony? There might be some conceivable meaning by substituting for it the expression "a drum tattoo." Most of us understand by harmony the combination of certain simultaneous notes. What has this to do with an alternation of activity and repose? In the last chapter, headed "Recapitulations and Conclusions," occurs the following: "There is hardly a conclusion of graver importance to humanity and resting on a less secure foundation than the generally accepted notion of the existence of an aim in life (p. 314) ..... the whole idea of purpose and aim in life, based as it is on erroneous conclusions, has, since the dawn of civilisation, proved itself the most potent factor in retarding and stunting humanity" (p. 317). The final conclusion is reached on p. 322: "Man will only become himself again when all values are swept out of existence, moral or otherwise ..... every faculty should be studied according to its peculiar nature ..... without aiming at any ulterior purpose. ..... Whither the activities of our impulses lead us is no business of ours to inquire ..... we are even unable to say that progress, for instance, is a more desirable state of existence than retrogression" (p. 323). For those who hold such views the book may be of interest.

JOURNALS AND MAGAZINES.

Quarterly Journal of Microscopical Science. Edited by Sir E. RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM SEDGWICK, M.A., F.R.S., SYDNEY J. HICKSON, M.A., F.R.S., E. A. MINCHIN, M.A., F.R.S., and GILBERT C. BOURNE, M.A., F.R.S. February, 1912. London: J. and A. Churchill. Price 10*s.* net.—The opening article of this number is on the Condition of the Epidermal Fibrils in Epithelioma, by Mr. George Arnold, M.Sc., from the Cancer Research Laboratory, University of Liverpool. His observations were made in the course of some experiments which were carried out with the object of demonstrating chondriosomes in malignant tissues. In the course of a synopsis of previous writings on the subject of epidermal fibrils and chondriosomes from those of Ranvier in 1879, to those of Meves in 1911, he states that the following nomenclature is now in general use: (1) Mitochondria, granules which may be arranged in chains or scattered through the cytoplasm; (2) chondriokonts, rod-like bodies or threads which may sometimes arise from the fusion of rows of mitochondria; and (3) chondriosomes, a general term to include all cytoplasmic structures which are of the nature of mitochondria or chondriokonts. Mr. Arnold's observations throw some light on the origin of the well-known "cell nests" occurring in epitheliomata, and also go to support the view of Rosenstadt that protoplasmic bridges between one prickle-cell and another do not exist. The material used was cut from the central portion of an epithelioma of the tongue tangentially to its free surface. Immediately after removal it was fixed in Flemming's solution, modified according to the formula of Meves for the specific staining of chondriosomes. The sections (5μ thick) were stained with Heidenhain's iron-alum hæmatoxylin and counter-stained with orange G. The microscopic appearances are minutely described in the memoir and figured in a coloured plate. The general conclusions are summed up as follows. The malignant cells composing an epitheliomatous growth undergo a gradual degeneration which may take two paths. 1. When the cell obtains an excess over the normal of fibrillar material the fibrils form a mantle round the nucleus which atrophies, and this is followed by the death of the cell. Such cells usually collect into groups and form the epithelial pearls or cell-nests. 2. In the other form of degeneration cells from which the fibrils have been withdrawn are brought to an end by the breaking down of the nuclear membrane, the dissolution of the contents into the cytoplasm, and finally by the fragmentation of the whole cell. Mr. G. R. Mines contributes a note on the Mechanism of Discharge of the Cuvierian Organs of Holothuria Nigra. It is well known that when this creature, the large sea-cucumber common at Plymouth, is irritated it responds by emitting a number of white conical bodies. These, the Cuvierian organs, rapidly elongate, shooting through the water while remaining attached at their bases to the animal, to form long, intensely sticky tubes. Mr. Mines found that by introducing a fine glass cannula or a hypodermic needle into the base of an undischarged organ and injecting fluid, the tube is shot out in precisely the same way as in a normal discharge by the living animal. The pressure needed to cause elongation of the tubes is about 20 or 30 centimetres of water. He also found experimentally that there was a rise of internal pressure in holothuria on irritation, and he believes that the discharge of the Cuvierian organs is due to forcible injection of the tubes with water. Freda Bage describes the Histological Structure of the Retina of the Lateral Eyes of Sphenodon Punctatus, with special reference to the sense-cells. The observations were made in the Zoological Department of King's College, London. After an exposition of the methods of preparation and a general account of the various layers of the retina, it is stated with regard to the sense-cells that sphenodon appears to form no exception to the rule that cones only are present, to the exclusion of rods, in the reptilian retina. It is generally admitted that oil globules do not occur in rods, but they are present in nearly all the visual cells in sphenodon. In this memoir the retinal cones of sphenodon are classified as (1) ordinary single cones; (2) small single cones; and (3) double cones subdivided into (*a*) near cones, and (*b*) far cones. The longest of the memoirs in the present volume is on the Problem of Sex Determination in Dinophilus Gyrociliatus, by Mr. Cresswell Shearer. In the conclusion of his paper, which is illustrated by a profusion of coloured plates, he states that the most singular feature of the phenomena observed was the peculiar manner of early fertilisation and the subsequent division of the sperm in the oögonial cells. This would seem to be without parallel, although something similar possibly takes place among the rotifers.

Journal of Pathology and Bacteriology. (Official Organ of the Pathological Society of Great Britain and Ireland.) Vol. XVI., No. 3. Published from the Department of Pathology, University of Cambridge. Price 7*s.* 6*d.* Yearly subscription, £1 1*s.*—Dr. Ernest E. Glynn and Dr. G. Lissant Cox, of Liverpool, in Further Observations upon Certain Sources of Error in the Opsonic Technique, record the results of an investigation into the effect of rotation of the opsonic pipette during incubation; rotation once every two minutes has the same effect on phagocytosis and experimental error as keeping the pipette stationary; a rotation once every half minute or less increases the error. If the leucocytes are allowed to stand in normal saline solution at room temperature for two hours the error is increased and there is diminution of the phagocytic capacity. An emulsion of staphylococcus in normal saline solution does not settle appreciably in two hours. Dr. J. F. Gaskell,

who carried out his investigations in Freiburg, describes the Changes in Glomeruli and Arteries in Inflammatory and Arterio-sclerotic Kidney Disease, and attempts to reconcile the pathological conditions found in various forms of contracted kidney with the clinical manifestations. The changes dealt with are divided into two groups: 1. Those accompanying and consecutive to inflammation of the kidney, in which lasting inflammatory changes are always due to true glomerulo-tubular nephritis. Interstitial and tubular inflammation alone does not lead to chronic changes. He distinguishes three stages: (*a*) the acute stage —acute parenchymatous nephritis; (*b*) the stage of repair—the large white kidney, in which death may or may not be due to the renal condition; (*c*) the sclerotic stage—the secondary contracted kidney, which usually causes death by uræmia at an early age. He also describes embolic focal nephritis, the ulcerative endocarditis type where the clinical picture is that of the cardiac condition. 2. Those primarily vascular in origin: (*a*) the senile arterio-sclerotic cases found in old people, where the vascular degeneration spreads from the large arteries to the renal vessels, and there being no hypertrophy of the heart, death is due to intercurrent disease; (*b*) the genuine *Schrumpfniere* cases with widespread vascular changes, especially in the brain, and marked hypertrophy of the heart. In this class death is usually due to cerebral hæmorrhage. The author claims that the microscopic picture is different in all these types of renal disease, and the paper is accompanied by plates giving examples typical of each condition. Dr. J. W. McLeod, of Glasgow, writing on the hæmolysin produced by pathogenic streptococci and on the existence of anti-hæmolysin in the sera of normal and immunised animals, says that by growing certain strains of pathogenic streptococci on bouillon containing from 15 to 20 per cent. of horse serum, previously heated for one hour at 56° C. and slightly alkaline to litmus, he is able to obtain actively hæmolytic cultures. The hæmolysin is not entirely endotoxin, and the filtrate obtained by using a Maassen or Doulton filter is actively hæmolytic, though to a less degree than the original culture. The streptolysin is greatly weakened by heating at 49° C. for 30 minutes and destroyed by heating at 55° C. for the same period; its power is unimpaired by placing it in the ice-chest for from eight to ten hours. The impairment which takes place under the above conditions is not due to formation of streptolysoid, but to the formation of a number of more feeble hæmolytic molecules, and partly also to the complete destruction of another portion of the molecules. In man, horse, rabbit, and guinea-pig an anti-hæmolysin is normally present in the serum—in equal amounts in the sera of different animals of the same species; it is not an albuminoid globulin, but is probably lipoid in character. Injection of the streptolysin into the ordinary laboratory animals fails to produce an immune anti-hæmolysin, nor is any such body to be found in the sera of men who have suffered from prolonged streptococcal infections. No hæmolysis follows the injection of the streptolysin into living animals. From an examination of many strains of streptococci from various sources, the author concludes that virulence and hæmolytic power are closely associated among the pathogenic streptococci. Dr. H. H. Dale and Mr. P. P. Laidlaw, of London, describe a Simple Coagulometer in the form of a narrow glass tube containing a small shot. The time of coagulation is that at which the shot fails to fall, when the tube, filled with blood, is held in a vertical position. The operation takes place in a water bath between 35° and 40° C. Sources of error are discussed and tables of results given. Dr. J. O. Wakelin Barratt, of Liverpool, in a paper on the Incomplete Fixation of Complement and Amboceptor, gives the results of an investigation into the extent to which complement and amboceptor contained in serum are withdrawn by the addition of small amounts of antigen, furnished by red blood cells. He concludes that the hæmolytic power of serum is unaltered by varying the proportions of amboceptor and complement present, provided that increase in the one is accompanied by diminution in the other. If complement and amboceptor are withdrawn from normal serum, by the addition of rabbits' red cells as antigen, the amounts withdrawn are proportional to the amounts present in normal serum. If the bodies are present in serum in proportions differing from those obtaining in normal serum the addition of antigen withdraws them in unequal amounts; if complement is present in excess, more complement than amboceptor is withdrawn, but if complement is present in subnormal proportions, the amount withdrawn is proportionately small. An obituary notice of Professor Henri Stilling, of Lausanne, is contributed by Dr. Marullaz. Abstracts of the Proceedings of the Liverpool Meeting of the Pathological Society of Great Britain and Ireland occupy 25 pages of the journal.

Jahreskurse für Aerztliche Fortbildung. Munich: Lehmann. Price 16 marks yearly.—As usual, the January number is given up to a review of general biology and pathology. Professor Johannes Müller contributes an article on the Nature of the Chemical Processes in the tissues, and Professor Lubarsch writes on the Pathological Significance of the Thyroid, Thymus, and Pituitary Glands. The first contribution discusses in considerable detail the essential nature of the chemical processes that take place in the cells of the body generally, with only passing reference to a few diseases, such as diabetes. The modern doctrine is expounded and illustrated that the protoplasm of the cell is in a state of high chemical instability, subject to the reactions of intracellular ferments which are reversible in their action (as Croft Hill was the first to point out). Certain of these ferments are well recognised, such as those bringing about autolysis, and the diastatic and lipolytic enzymes of the tissues. The synthesis of the complicated molecules in protoplasm is due to the reversed action of the same ferments, energy being supplied by the absorption of heat, whereas when these substances are resolved into simpler components heat is evolved. Professor Lubarsch describes briefly the effects of removing the thyroid gland in man and animals, and gives a description of the parathyroid glands, which are believed to regulate the calcium metabolism of the body. Changes have been described in them in cases of tetany, osteomalacia, puerperal eclampsia, and other diseases in man. Just as the parathyroids regulate the calcium metabolism, so the thyroid deals with the iodine and phosphorus compounds of the body. An account is given of the changes in the various organs in cretinism. With regard to the causation of goitre, it is pointed out that after heating the water of the famous Kropfbrunnen (goitre-wells) to 80° C., it will no longer induce the disease in animals. But passing it through a Berkefeld filter does not alter it in this respect (Wilms, Birscher, Kolle), which is evidence against a bacteriological causation of endemic goitre. The pathology of Graves's disease and its relation to iodine are discussed at length, also the "thyroid heart" and the various somatic and visceral abnormalities. The review closes with an excellent account of the relation of the thymus to disease, and especially to sudden death; followed by a few words on acromegaly and splanchnomegaly in association with lesions of the pituitary gland.

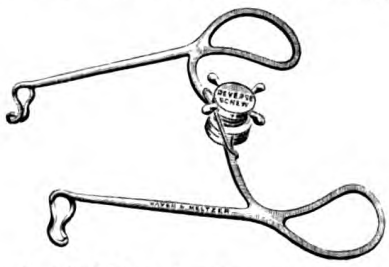
The February number contains an article by A. Hoffmann on Cardiac Weakness, and another by R. Staehelin on the Causation and Treatment of Bronchial Asthma. Hoffmann points out that we no longer rely, as we once did, principally on the occurrence of murmurs or on enlargement of the area of cardiac dulness to make a diagnosis of impairment of the heart's action; the latter,

in some circumstances, may even be a favourable sign Later came a time when irregularity of the pulse-rate was regarded as of grave significance, but now we know that it may persist for years. Attention has more recently been directed to the blood pressure and to observation of the electro-cardiogram. He discusses heart weakness under the headings of Absolute Cardiac Insufficiency, in which the heart is unable to do its ordinary work without disturbance, and Relative Cardiac Insufficiency, in which it can respond to ordinary, but not to extraordinary, demands upon it. It is much easier to diagnose the first than the second, which includes those cases in which the heart falls under the influence of anæsthetics, operations, confinements, and so on. Warning may be given by such signs as dyspnœa or cyanosis. Blood-pressure measurements, plethysmography, Sahli's sphygmobolometer, or electrocardiography may also be of assistance. The treatment of both conditions is discussed, reference being made to exercises, baths of various sorts, and drug treatment by digitalis, camphor, caffeine, and other well-known substances. There is a brief summary of recent researches on the heart, in which the work of Lewis, Keith, and other English observers is mentioned as well as that of a number of Germans. Staehelin passes in review the various theories of the causation of bronchial asthma, the diaphragmatic cramp theory, the bronchial spasm theory depending on vagus impulses, the secretion theory based on the occurrence of Curschmann's spirals, Charcot-Leyden crystals, spangle-epithelium, and eosinophile cells, and the theory of swelling of the bronchial mucous membrane. He thinks it probable that the underlying factor is a vagus impulse leading to all three of these changes. With regard to treatment of the attack, the psychological factor has to be considered, also various methods for altering the rhythm of the breathing. Of drugs, morphia is given the first place. Atropine and adrenalin are also discussed. Between the attacks, potassium iodide may be given, and measures taken to deal with nasal polypi, pharyngitis, or constipation, all of which may provoke the spasms. Preparations of atropine are recommended, and so are the various nasal inhalations, which may be combined with cocaine. The breathing of asthmatics must be disciplined, and suggestion and hypnosis sometimes have a place in the treatment.

New Inventions.

RETRACTOR FORCEPS FOR MINOR SURGERY WOUNDS.

THE forceps illustrated below owes its efficacy to two points: the eccentric arms increase the working gap or degree of excursion; and the pivot, provided with a reverse screw, stops the inward thrust of the arms when extending the sides



of the wound. The kidney-shaped handles give a better hold, and, when the instrument has been fully extended, they overlap or occupy less space. My design has been carried out by Messrs. Mayer and Meltzer, Great Portland-street, London, W.

H. ELLIOT-BLAKE,
Bognor. M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.

BRITISH MEDICAL BENEVOLENT FUND.

AT the February meeting of the committee 28 cases were considered and grants amounting to £281 made to 27 of the applicants. Appended is an abstract of the cases relieved:—

Daughters, aged 50 and 48, of M.D. Aberd. Means very slender and health indifferent. Voted £2, and application to be reconsidered.

Widow, aged 45, of M.D. Edin. Has been in very poor health since the death of her husband last year, and asks for a little help to meet unavoidable expenses. Voted £5.

Widow, aged 50, of L.R.C.P. Practically unprovided for at husband's recent death after a long illness, but hopes to maintain herself and her children by taking boarders. Voted £10.

L.R.C.P., L.R.C.S. Edin., aged 55. Asks for a little help to tide over difficulties, which are quite expected to be temporary. Voted £10.

Widow, aged 46, of M.B., C.M. Aberd. Husband's savings quite exhausted by a long illness ending in death, and although temporarily earning sufficient to support herself, has incurred heavy expenses owing to the ill-health of a daughter recently deceased. Voted £10.

M.R.C.S., aged 55. Has had bad health for the last ten years, and has recently been incapacitated for several months, during which his practice has almost disappeared and unavoidable debts have been incurred. Proposes to make a fresh start in the colonies. Voted £10 towards passage money if emigration is decided on.

Widow, aged 41, of M.B., C.M. Edin. No income; has recently lost her husband after a two years' illness, and has five children to support. Voted £12.

M.R.C.S., aged 84. Only income a small Poor-law pension. Relieved twice, £24. Voted £12.

Daughter, aged 55, of late M.R.C.S. No income, and through failing eyesight is unable to earn more than a few shillings a week, which goes to support not only the applicant but two sisters who are quite unable to earn their living. Relieved twice, £36. Voted £18.

Daughter, aged 60, of late M.R.C.S. No income, and unable to earn a living on account of a painful deformity. Voted £12.

Widow, aged 56, of L.R.C.P. Edin. No income and practically dependent on a daughter earning only a few shillings a week. Relieved twice, £20. Voted £12.

Widow, aged 42, of M.R.C.S., L.R.C.P. Since husband's death, three years ago, has been endeavouring to establish a boarding-house, but has now exhausted her small capital. Three children, aged 13 to 6. Relieved twice, £24. Voted £10.

Widow, aged 52, of L.R.C.S. Edin. No income; endeavours to support herself by nursing, but has no certificate. Children unable to help. Voted £12.

Daughter, aged 63, of late M.R.C.S., L.S.A. Supplements a small pension from a charitable society by taking boarders, but finds increasing difficulty in meeting her expenses Relieved once, £10. Voted £10.

Widow, aged 67, of L.R.C.P., L.R.C.S. Edin. No income and unable to obtain employment; no children. Relieved four times, £34. Voted £12.

Daughter, aged 37, of late M.R.C.S. Is a nurse by profession, but unable to support herself as such owing to incurable deafness, and is consequently dependent upon uncertain earnings from needlework, &c. Relieved seven times £63. Voted £10.

M.R.C.S., aged 77. Was appointed doctor to a Medical Aid Association 18 months ago but has found it impossible to obtain his salary. Relieved once, £18. Voted £6.

Widow, aged 63, of M.R.C.S. Had a little capital at husband's death some years ago, but lost it in the attempt to establish a boarding house and is now quite without means. Relieved once, £12. Voted £12.

Daughters, aged 71 and 64, of late M.R.C.S. Were fairly provided for at father's death but have lost practically everything through unfortunate investments and are now living together in a bed-sitting room. Relieved once, £18. Voted £18.

Widow, aged 70, of M.R.C.S. Nursed and supported her husband for several years and is now dependent for a home on a son-in-law who can ill-afford to help. Relieved twice, £20. Voted £10.

Widow, aged 67, of L.F.P.S. Glasg. Has supported herself with occasional grants from this fund, since her husband's death 38 years ago, but is now dependent on a daughter earning £1 a week as a cashier. Relieved seven times, £72. Voted £12.

Widow, aged 67, of M.R.C.S. Only income a small pension from another charity, and is frequently laid up for some months together owing to a chronic affliction. Relieved seven times, £64. Voted £5.

Daughter, aged 61, of late L.S.A. Has supported herself for several years by letting lodgings, but finds increasing difficulties owing to ill-health and competition. Relieved three times, £36. Voted £12.

Widow, aged 62, of M.R.C.S. Quite unprovided for at husband's death five years ago, and endeavours to maintain herself by receiving boarders. Children only just self-supporting. Relieved once, £12. Voted £10.

Widow, aged 62, of M.R.C.S. Quite unprovided for at husband's death, and dependent on a married son earning a small weekly wage as a shop assistant. Relieved eight times, £94. Voted £12.

Widow, aged 62, of M.R.C.S. No income, and health indifferent; children only able to give slight assistance. Relieved 13 times, £147. Voted £12.

Widow, aged 53, of M.R.C.S. Since husband's death has tried to support herself by taking boarders, and is now in difficulties which she hopes will be temporary. Relieved twice, £22. Voted £5.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, W.

A CONFERENCE ON DIET IN SCHOOLS.—The National Food Reform Association is making arrangements for a conference on diet in public secondary and private schools to be held at the Guildhall, London, on Monday, May 13th. The Lord Mayor will preside at the opening session.

THE LANCET.

LONDON: SATURDAY, MARCH 16, 1912.

The Report of the Royal Commission on Vivisection.

THE report of the Royal Commission on Vivisection has at last been completed and published; and we are happy to be able to speak favourably of its recommendations, which throw only a single small sop to unreason, and in the main both satisfy the minimal requirements of the medical profession and protect the public against any dangerous interference with that prosecution of research which is necessary both for the continued improvement of the art of healing and for the attainment of increased power to prevent the occurrence of disease. The opponents of experimentation upon animals have very generally endeavoured to confuse the public mind by representing that experiments are performed in the interests of the medical profession alone, and that it is the duty of enlightened persons to protect the lower animals against cruelties which are perpetrated for the mere gratification of curiosity. The truth is, as everyone knows who has given a moment's impartial consideration to the subject, that an increased knowledge either of the causes or of the means of cure of disease is a direct and actual gain to the public, and is in some degree a loss to the medical profession, whose services are less in demand when the occurrence of disease is prevented, or when its course is curtailed by effective remedies, than when neither of these conditions is fulfilled. We have a crucial example in the case of rabies in the dog, with its necessary complement of hydrophobia in the human subject. The nature of the disease and the channels of its diffusion were made known by experiment; and this knowledge having been applied in practice by the sagacity of Mr. WALTER LONG, without regard to the clamour of ignorance, the disease has disappeared from this country, and need never be permitted to return. Its absence cannot be said to have been of any special advantage to the medical profession, whose chances of infection were comparatively small, and whose aggregate remuneration must to some extent have been diminished; while it is noteworthy that the experiments by which the nature of hydrophobia was elucidated have also served to throw much light upon other obscure maladies of the cerebro-spinal system, such as epidemic meningitis and poliomyelitis. The fact is that, with improved methods and instruments of research, fresh questions are daily offering themselves for solution, and that these questions can only be solved by experiment. There has been no other method of discovering truth in the past, and it is certain that, so far as can be foreseen, no other is likely to present itself in the future.

The profession has borne with exemplary patience the accusations of wanton cruelty which have been brought against medical men of the highest distinction, and have probably thought that the personal peculiarities of the accusers furnished a sufficient refutation of them. They will none the less be gratified that these accusations have been carefully examined and tested by the Commissioners, and that the verdict based upon personal knowledge has been absolutely ratified by systematic inquiry. The stock agitators are dismissed with a few brief words, the Commissioners declaring that the existing Act has been administered by successive Home Secretaries and their subordinates "with good faith and with careful consideration of its terms," and that the holders of licences and certificates, with rare exceptions, "have endeavoured with loyalty and good faith to conform to the provisions of the law." It is further said that those who came before the Commission to give testimony in support of charges of cruelty "have either misapprehended or inaccurately described the facts of the experiments," and it is courteously contended that the witness must have been mistaken who described the results of an operation which had never been performed. This was the case of the marmot, which was for the time in a state of partial paralysis as a consequence of imperfect recovery from its natural hibernation, and which was said by Miss LIND-AF-HAGEBY to have had its spinal cord divided. As a matter of fact, nothing had ever been done to it, and it lived for two years after the alleged operation in perfect health. After dealing with such cases the Commissioners go on to warn the public against the falsehoods contained in circulars and advertisements which are freely distributed through various channels, and which they describe as calculated to mislead the public by suggesting that the animals in question were not under an anæsthetic. To represent that animals subjected to experiments in this country are wantonly tortured would, in the opinion of the Commissioners, be "absolutely false." They are, nevertheless, solicitous on the subject of pain which may be produced as an after consequence of experiment, as, for instance, of an inoculation which causes disease, and they desire the framing and enforcement of regulations under which animals thus suffering should be destroyed immediately, whether the object of the experiment had or had not been attained. It is mainly upon this point that Colonel LOCKWOOD and Sir WILLIAM COLLINS have added a memorandum to their signature of the general report, a memorandum in which they ask for more stringent regulations on this point than those with which the majority of their colleagues would be satisfied. Dr. GEORGE WILSON adds his signature both to the general report and to the memorandum, and appends also a long memorandum of his own, which is critical of the results obtained by vivisection. It seems obvious that a cast-iron rule to destroy every animal that was, or that to some inspector might appear to be, in pain after an experiment, even although the object with which the experiment was performed had not been attained, would in the long run defeat itself, and would be certain to multiply similar experiments in the hope that manifestations of pain might be avoided. The Commissioners rightly call attention to the fact that public opinion sanctions the infliction of

pain for the purposes of sport, for such operations as castration and spaying, and for the destruction of vermin by traps or painful poisons; and it is manifestly absurd that what is permitted on these grounds should be absolutely prohibited when the attainment of useful knowledge is at stake.

The Act under which experiments on animals are now conducted was passed in 1876, and every one of the intervening years has afforded fresh evidence of its value. In the interval the two great English Schools of Tropical Medicine, the London and the Liverpool, have come into existence, and have justified the wisdom of their founders by the continued discovery of new truths concerning the nature and causation of maladies by which extensive portions of the earth's surface have been closed to civilised man, or were only penetrated at the cost of almost certain death. The interval covers practically the whole attainment of the knowledge of the present day concerning the conveyance of disease by blood-sucking insects—a knowledge which promises eventually to open up the greater portion of the African continent to colonisation and industry. It has shown that the flea is an active cause of the diffusion of a malady which is even now destroying thousands of lives annually, and it has cast grave suspicion upon the bug as a possible means of communication of leprosy, the bacilli of which are said to have been discovered unharmed in the alimentary tract of the insect some considerable time after they had been ingested. The great home question of tuberculosis has been only sufficiently elucidated by experiment to show the directions in which further research is required; and the institution and conduct of such research is one of the most pressing medical necessities of our day. It is a great relief to all right-thinking people to know that the splendid work of the recent past will be continued with the added prestige conferred upon it by this report. The recommendations of the report, which we shall later deal with in some detail, contain nothing which should hamper the progress of science, while the document is a remarkable reply to the malignant abuse under which much of that progress has been made.

A "Mental Defect Bill."

THE statements made in the House of Commons by both the Prime Minister and the Home Secretary that it was the intention of the Government to introduce during the present session a measure for the care and control of the feeble-minded must have been received with satisfaction by the many persons who are interested in this pressing social reform. It is now four years since the Royal Commission appointed to investigate this subject, after a like period of exhaustive inquiry, made its report, which included a long series of recommendations as to the needed legislation. These recommendations comprised a well-considered scheme covering the whole ground, based on the broad fact that mental defect which renders an individual unable to control himself or his affairs is widely met with amongst individuals who at present enjoy full liberty, and who need legalised protection. For whilst there is statutory provision for the care of the insane and the idiot, there is none for the mental weakling or the wastrel, whose unrestricted freedom is quite as harmful to the well-being of the community. These classes contribute largely to the multiplication of the unfit, and are themselves exposed to dangers and hardships by reason of their own unfitness. Unable to earn a livelihood they swell the ranks of pauperism, whilst their lack of mental and moral control leads to their contributing no small share to the records of crime, intemperance, and immorality. The Royal Commission did a great service in revealing the extent of the evil resulting from the lack of supervision over this large and increasing degenerate section. That the revelations have not hitherto engaged the attention of Parliament cannot surely be due to non-recognition of their importance, but rather to the absorption of political activities in other directions. It may be that the delay in dealing with the question has not been without advantage, since it has allowed time for the public to be fully enlightened by much able propagandism, so that few can now be wholly ignorant of the urgency of the problem, and the means of dealing with it. And since so to deal with it adequately must needs involve a large expenditure of public money, it is perhaps as well that the bearing of legislative interference on the promotion of the national health and efficiency should be thoroughly and widely realised.

As if in anticipation of early legislation on the subject there has opportunely been published the draft of a Bill styled "The Mental Defect Bill," which has been prepared on the lines of the report of the Royal Commission under the auspices of a highly influential and experienced committee. The Bill[1] consists of 259 clauses grouped under 14 headings, and is mainly framed on the Lunacy Act, 1890, of which the material parts are retained or redrafted, the term "mentally defective" replacing that of "lunatic," and "hospital" being substituted for "asylum." The arrangement of the clauses is decidedly better than obtains in the existing Act, and there are skilfully embodied in them many of the recommendations of the Royal Commission. There are many points in regard to which experience of the working of the Lunacy Act has shown the necessity for amendment, and these may have to be considered before a Bill replacing that Act is finally framed; but there can be no doubt as to the general scope and bearing of this draft. For it shows the possibility of dealing with every class of the mentally defective on the same lines as those of existing legislation for "persons of unsound mind." Those who need care and control by reason of mental incapacity of the simplest as well as of the gravest form will, under such a measure, be subjected to practically identical disabilities and restrictions, be detained and segregated under the same legal procedure, and be able to enjoy the same benefit in regard to the protection of their property. There must be some difference in detail, but in principle all mental defectives would be controlled by similar means. Should this principle be generally recognised one step would have been taken towards dispelling what is called the

[1] Copies of this Bill are to be obtained at P. S. King and Co., Smith-street, Westminster, or 296, Vauxhall Bridge-road, S.W. Price 6d.

"stigma" of insanity, and so removing the popular dread of certification. Although it would hardly be desirable at this juncture to enter into a minute discussion of the details of a "Bill" which is rather of the nature of a *ballon d'essai* than of a measure introduced into Parliament, it may yet be useful briefly to indicate some of its novel provisions, especially as regards our profession. For it may, we think, be taken for granted that whatever be the legislation ultimately proposed it must be more or less on the same lines as this draft if not of the same scope.

Following the recommendation of the Royal Commission, no new authority is to be set up, but the central body for the care and control of the feeble-minded is to be a Board of Control consisting of Commissioners, including the existing Commissioners, Masters, and Chancery Visitors, together with such additional Commissioners as may be necessary, the appointments being made by the Secretary of State. Those eligible shall be a certain proportion of legal and medical practitioners or others specially qualified from their knowledge and experience of the care of mental defectives, and at least one of the Commissioners must be a woman. There would also be Honorary Commissioners and eight Assistant District Commissioners, who would be medical men, and whose duties would be confined to the eight districts into which the country would be divided. It may be noted in passing that if the Bill introduced by the Lord Chancellor last session had been passed in its original form a step would have been taken towards the formation of such a Board of Control, by the amalgamation of the two existing lunacy boards. In the next place, each local authority (the county or borough council) will act through a statutory committee, the "Mental Defect Committee," which would take over the duties at present performed by the Visiting Committee of Asylums, and part of those of the Education Committee, and on this committee at least one woman would have a seat. It would be the duty of the local authority to appoint a whole-time medical officer (or, if need be, more than one) to assist in carrying out the provisions of the Act; and also to appoint certifying medical practitioners in districts within the area, subject to the approval of the Board of Control.

Amongst other new proposals which are very desirable is that of the provision by the local authority of receiving houses and reception wards for the temporary treatment of mentally defective persons, whose admission therein is subject to the discretion of the medical officer of the house or ward, and if admitted such persons will have to be visited by the medical officer of the local authority or by a certifying medical practitioner, on whom will devolve the duty of reporting on the mental state of the person. Apparently there would be no change in the existing procedure of reception orders on petition or of summary reception orders, except that in certain contingencies the local authority may call on their medical officer to act as petitioner. The regulations bearing on care and treatment would be unaltered, but fresh powers would be given to local authorities in respect of the discharge of a mentally defective person, "not being a person of unsound mind." The local authority will have to deal with the education of mentally defective children, the term "education" being held to include any manual, industrial, or other training, and the phrase "mentally defective child" being a child who is either an idiot, an imbecile, feeble-minded, or a moral imbecile. There are also clauses dealing with the guardianship and supervision of those who are under the age of 21. A register of all notified mentally defective persons is to be kept by the Board of Control, and the requirements as to visitation and inspection are to be much as now obtain for the insane, with the not unimportant modification that these duties in any instance may be made by a single Commissioner. The reintroduction of licensing of houses and institutions, which was abrogated by the Act of 1890, is obviously necessary, since the need for new establishments will be very great.

The foregoing forms but a small part of the provisions of this bulky measure, which has evidently been compiled with the careful intention to bring new legislation into harmony with old. It shows how this can be done without any departure from the spirit and intention of the existing lunacy law, and so far it merits approbation. It is of value, too, as consolidating and bringing to a focus the conclusions arrived at by a Royal Commission of exceptional strength after a thorough survey of the problem they were empowered to determine. It may be too much to expect that so great a step as is here foreshadowed can be taken by Parliament at once, but it shows the way in which the subject could be dealt with in its entirety. If it be only practicable to proceed by piecemeal legislation, whatever is done now should be done with the general scheme in view as the ultimate goal. Perhaps the one striking feature of the whole plan is that it would extend the range of legalised restriction of liberty of individuals, in the interest of themselves and of the rest of the community, to fully twice its present limit. And in the case of the congenitally feeble-minded this restriction must be life-long, and therefore will apparently involve for them a greater hardship than is now endured by many of the insane. All the more reason then that the conditions under which they would have to pass their lives should be made as pleasant and as free as is compatible with their segregation and protection. We may feel sure that humanitarian instincts may be trusted to find the best solution to this problem. And we are equally confident that under the new conditions that will soon prevail the medical profession would be willing and competent to undertake the very responsible duties devolving upon them.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—Hospitals in the County of London or within nine miles of Charing Cross desiring to participate in the grants made by this Fund for the year 1912 must make application before March 30th to the honorary secretaries, 7, Walbrook, E.C. Applications will also be considered from convalescent homes which are situated within the above boundaries or which, being situated outside, take a large proportion of patients from London. Applications will also be considered from sanatoriums for consumption which take patients from London or which are prepared to place beds at the disposal of the Fund for the use of patients from London hospitals.

Annotations.

"Ne quid nimis."

SENIOR HOSPITAL APPOINTMENTS AND DISPENSING.

OWING to local circumstances of a rather unusual kind the question of the senior hospital staff and dispensing has lately been revived at Portsmouth. Like several other large provincial hospitals the Royal Portsmouth Hospital has a rule prohibiting the honorary senior physicians and surgeons from dispensing or contracting in any way for the supply of medicines. As it happens, the neighbourhood of Portsmouth and Southsea is sharply divided so far as medical practice is concerned into two distinct parts—all the medical men south of a certain street refrain from dispensing and are eligible for senior staff posts, while all those practising north of this line dispense and are debarred from promotion to the senior honorary staff. The death of one of the senior physicians to the hospital recently created a vacancy which, had he been eligible, would naturally have been filled by the promotion of a much respected junior honorary physician. He, however, dispensed, and owing to the effect of the Insurance Act upon the transfer of such practices he had been unable to dispose of this part of his work; therefore his election to the senior staff was prevented by the rule in question. This was very generally felt to be a hard case, and the governors of the hospital decided, not without some discussion, to propose that the words which forbade dispensing should be struck out. At the annual meeting, however, the case for retaining this prohibition was ably presented by Mr. Henry Rundle, a valued member of the consulting staff, who supported his argument with the opinions of Sir Clifford Allbutt, Professor Howard Marsh, Dr. J. Mitchell Bruce, and Mr. D'Arcy Power. He urged the meeting not to alter the rule for all time, and so lower the standard of qualification required of the senior staff, but to empower the governors merely to suspend operation of the rule for a period, so that the present difficulty might be overcome without prejudice to the future. Mr. Rundle's views carried much weight, and his amendment was passed by a very large majority. The essential thing, of course, is to secure for the service of the hospital the most scientific representatives of medicine and surgery available in the community, and any regulation which aims at this should be treated with respect, and not cancelled without good cause being shown. The question whether the senior members of the visiting staff should be allowed to dispense is not often likely to become a very acute one, because in the nature of things the senior practitioners of a large town by the time they are eligible for such posts have already ceased to dispense, or are in a position to do so if they wish. It is obvious that in ordinary circumstances a medical man whose practice is so dependent upon the supply of medicines that he cannot afford to abandon dispensing would be unlikely to have sufficient time to devote to the honorary service of a hospital; but where special conditions arise, as at Portsmouth, it may be wise to relax a good rule to avoid injustice. It would have been unfortunate if a rule framed in the best interests of the hospital and of the community had been abolished because its operation in exceptional circumstances might give it the air of class legislation. Mr. Rundle showed that the position could not well arise again at Portsmouth for 15 years, since none of the present assistant honorary staff dispense. Such being the case his amendment offered a middle course which appealed to the good sense of the meeting, and will, we hope, satisfy all parties.

THE SURVIVAL OF ANCIENT PATHOLOGY AMONG THE LAITY.

THE history of medicine shows that many pathological theories, like most other subjects of human interest, after claiming attention for a shorter or longer time, pass ultimately into the limbo of the forgotten. As a rule, each new doctrine finds its earliest adherents within the boundaries of the profession, and spreads but slowly among the laity. By the time it is incorporated in the stock ideas of the common people, those who originally set it up have tested it, and have reason on their side if they find it wanting. The longer the doctrine maintains its hold over the intellectual centre, the more likely it is to reach the understanding of the people, and as a rule the more likely is it to be defensible, in some aspects at any rate, on scientific grounds. The ancient humoral pathology, which reigned supreme for 2000 years, and had ample opportunity to permeate all levels of society, incorporated in its imagining many isolated truths. Its main ideas are reflected time and again, as Mr. P. A. Robin [1] has pointed out, in the literature of the ages. Even at the present day our language still shows traces of this ancient pathology. For example, Hippocrates' notion of the four humours of the body survives in the expressions "choleric," "sanguine," "melancholic," and "phlegmatic"; while the words "good humour" and "ill-humour" spring from the same remote source, and the word "spleen" owes one of its special meanings to its rôle in the humoral pathology as the producer of black bile. It would be strange if in the daily talk of average men and women nothing now remained of beliefs that dominated the medical world for so many centuries, especially as very few people even among educated classes have any clear idea of what they mean by a "disease"; in the minds of most it has something of the concrete about it, which the "constitution" can throw off or eject. Thus, most people regard a cold as a something that can be sweated out through the pores of the skin, and the rash of a specific fever as "the disease coming to the surface"; without the rash the disease would "strike inwardly" or be "suppressed." Similarly, a skin affection is to them a "breaking out"—a term expressing something pent up within the system. When a farm hand, admitted to a hospital for a broken-down gumma, which under the iodides is healing rapidly, insists on leaving the hospital in consequence of his conviction that the disappearance of the discharge implies the driving of the disease inward again, he is merely giving expression to the beliefs of our not very remote professional ancestors. So late as the seventeenth century the enlightened Sydenham believed, with Hippocrates, that a disease passed through a stage of "coction," in which it was prepared for elimination, to a stage of "crisis," in which it was expelled. He speaks of "inflamed particles" falling on the pleura and lighting up pleurisy; of withdrawing "febrile matter" from the blood by purging. In ague, he says, "sensible morbid matter" accumulates between the attacks and is cleared off in the sweating stage of the next fit. He recognised "depurating" fevers—fevers which cleansed the fluids of the body—and he made a free use of bleeding in order to remove the particles of disease. This medical conception still hovers at the back of the minds of many, not only of the lower classes, showing itself in their narratives of "breakings-out" and "suppressed" diseases; the determination of the out-patient mother who will be no party to the direful act of stopping the discharge from her child's ear is an expression of belated wisdom, though so foolish. Popular notions of disease, when looked at from the historical standpoint, appears as the fruit of the seed

[1] Old Physiology in English Literature, by P. A. Robin.

scattered by our professional predecessors, all of whom helped in moulding the lay opinion of their day. When we have to listen to a nineteenth century exponent of sixteenth century pathology it behoves us to remember that, in spite of the brilliant advance of modern medical science, a large proportion of our fellows have not yet freed themselves from the pathological doctrines of the ancients which were instilled into them by our professional forebears.

THE FATE OF MEDICAL CASE-BOOKS.

A FEW weeks ago we chronicled the munificent bequest of over £100,000 for the foundation of local almshouses by the late Dr. Charles Alfred Lee, of Hull. Dr. Lee's will contains precise instructions for the carrying out of his wishes. Among other instances of his foresight and generosity is a direction to his executors to cancel all his medical book debts and to burn all his day-books, cash-books, ledgers, and so forth, kept in connexion with his practice. This instruction no doubt covers any medical note-books and case-histories which may have been kept by the deceased practitioner during his 63 years of professional life. If this was part of Dr. Lee's intention when he made his will we may suppose that he had in mind not only the pockets of his patients, but also their feelings and the sanctity of his relations with them. He may well have considered that it was part of a medical man's duty to have all such intimate records of his patients and their families destroyed at his death for fear, among other things, lest they should pass into undesirable hands. The possible fate of old case-books after their owner's death is, indeed, too seldom borne in mind by medical men. The hard-worked general practitioner, it is true, often has time for little more than a brief record even of unusual cases, but many consultants keep full notes of every private patient, and the disposal of such elaborate case-histories should not be left to the whim of an executor. The death of a popular physician, whose practice has for many years brought him into close touch with the secrets and the troubles of well-known people, may place in lay hands a shelf-full of case-books of the greatest interest and scientific value, which, if allowed to drift about, might cause infinite pain. In such instances clear directions for the destruction or the sealing-up for a number of years of all professional documents would relieve executors of an embarrassing responsibility.

THE NERVOUS COMPLICATIONS OF DIABETES.

Dr. R. T. Williamson, of Manchester, contributes to the *Festschrift* in honour of Professor Raphael Lépine, of Bordeaux, an interesting paper on those nervous complications of diabetes which are associated with changes in the peripheral spinal nerves and spinal cord. Such nervous symptoms occur in the course of many cases of diabetes mellitus, mainly, though by no means entirely, in the milder forms of diabetes of long standing. As a rule they are confined to the sensory side of the nervous mechanism, revealing themselves by pains, paræsthesiæ, or tenderness, loss of the tendo-Achillis reflexes, and loss of the sensation of vibration, or pallanæsthesia. Sometimes only one or other of these is present, sometimes all; occasionally additional symptoms develop, such as marked hyperalgesia, loss of knee-jerks, slight anæsthesia, and even paresis or paralysis of the leg muscles. Dr. Williamson found the Achillis jerks absent in 19 out of 50 consecutive cases of the disease. In a series of 100 cases, chiefly among hospital patients, the knee-jerks were both lost in 49, one lost and one present in six, both present in 45. The Achillis jerks are usually lost before the knee-jerks. Of 100 consecutive cases of diabetes the sensation of vibration in the lower extremities was absent in 18. Dr. Williamson quotes from Verneuil the interesting observation that in cases of fracture in diabetic patients the ends of the bone are remarkably insensitive. The pains of diabetes are commonly described as dull, aching, gnawing, or burning; they are practically never of a darting, stabbing, neuralgic type. Pains and loss of the tendon reflexes constitute the main indications of "diabetic neuritis," so-called. Associated with the pains are often cramps in the muscles and general hyperæsthesia of the limbs. Sometimes a degree of ataxia is present, in which case the symptoms form a clinical picture not unlike locomotor ataxia, distinguished as "pseudo-tabes." As a rule the arms escape, and psychical symptoms are never observed. Very occasionally perforating ulcers are seen in diabetic patients on the soles of the feet. It is a curious fact that the symptoms of diabetic neuritis are sometimes localised to the distribution of the anterior crural and obturator nerves of one or both sides. Dr. Williamson holds strongly that whenever neuritic symptoms are localised to the distribution of the lumbar plexus the urine should always be examined for sugar. There should be little difficulty in distinguishing diabetic neuritis from alcoholic neuritis. It seems, for instance, to be the case that in the former condition the arms and the legs are never affected together, whereas the converse holds good for alcoholic neuritis. Nor should it be difficult to separate diabetic neuritis from tabes. It is a good rule always to examine for sugar when there are severe pains in the legs, when the knee or Achillis jerks are absent, or when the patient suffers from sciatica, or perforating ulcer, or from symptoms of peripheral neuritis. As for the pathology of diabetic neuritis, there are usually changes in the peripheral nerves or in the spinal cord. As far as the former are concerned, the changes are such as are found in any neuritis, alcoholic, diphtheritic, or otherwise. In other cases, however, more especially where the tendon reflexes have been awanting, degenerative changes have been found in the posterior columns of the spinal cord, affecting mainly the posterior root fibres in their intramedullary course. Dr. Williamson has found that these changes commence directly the nerve fibres have penetrated the pia and are entering the cord. The degeneration in the posterior columns is secondary to this root degeneration. The diseased areas can be easily traced by Marchi's method. They are best seen in the lumbar and cervical regions. The possibility of the nervous symptoms being due in part, at least in some cases, to alcohol is worthy of consideration. It has been pointed out that peripheral neuritis is specially apt to occur when two poisons act simultaneously on the nervous system. Dr. Williamson recalls the fact that in the epidemic of peripheral neuritis in Manchester some years ago the quantity of arsenic in the beer consumed was by itself insufficient to have produced the symptoms, and so was the quantity of alcohol, but the combination of the two proved an adequate cause for the development of neuritis.

CULTIVATION OF THE LEPROSY BACILLUS.

IT is satisfactory to find that the most refractory organisms are gradually yielding to the seductions of the bacteriologist, and submitting to cultivation in the laboratory. For a long time failure attended all attempts to grow the bacillus of leprosy on artificial media, but recently several successful cultures have been recorded. One of the most notable of these was effected by Clegg,[1] who grew the organisms along with amœbæ and cholera vibrios. This method has recently been successfully applied by Hollmann[2] to the bacillus of

[1] Philippine Journal of Science, 1909, sec. B., vol. iv., p. 403.
[2] Public Health Reports, Washington, Jan. 19th, 1912, vol. xxvii., No. 3, p. 69.

rat leprosy, which has been supposed to be identical with the bacillus found in the human disease. This identification is, to some extent, supported by the susceptibility of the two organisms to the same mode of culture. Reinoculation of Hollmann's cultures into healthy rats did not, however, produce any visible lesions, though acid-fast bacilli were found after death in the tissues of the animals, and in view of the ubiquity of acid-fast organisms it is difficult to be sure of the identity of any grown in a mixed culture. If the bacillus of rat leprosy is really the B. lepræ, the interesting question arises as to the possibility of transmission of the disease to man by these rodents. So far no evidence of such transmission appears to exist, and it is difficult to imagine a condition of sufficiently close contact between man and rat to lead to infection with the causal agent of so chronic and slightly contagious an infection. An intermediary, such as the flea, is, of course, possible, and it is important to ascertain whether fleas can carry infection from rat to rat. In any case we are justified in feeling that light is beginning to dawn on the causation of leprosy and in anticipating further discoveries of importance in the immediate future.

CRUELTY TO POULTRY.

THE Society for the Prevention of Cruelty to Animals has lately prosecuted a railway company because some sheep and pigs were so overcrowded in trucks that three died and many were injured before they reached their destination. On such a charge, if proved, a private trader could easily be condemned, but it is a more difficult matter to prosecute so impersonal an organisation as a large company. In any case, there is undoubtedly much unnecessary cruelty practised in effecting the transport of living animals intended for human food. Some of this could be stopped through the Protection of Animals Act, but there are many cases which do not come within the scope of the law. According to the Act in question, birds are not animals. If a horse, a cow, a pig, a dog, or a cat is ill-treated the person responsible can be prosecuted, but that same person may ill-treat a fowl or a turkey without interference. The result is that living poultry are packed and distributed all over the country in a manner that is a disgrace to our humanity. Heavy and light birds, geese and chickens, are crowded together in the same crates. The basket or crate is often so badly constructed that when the birds it contains are thrown against the sides they may be badly injured. In many instances there are projecting nails or splinters that inflict desperate wounds, while weaker birds are often smothered by the heavier birds and many limbs are broken. Of course, there should be partitions in the crates so that the birds could be separated according to their size. Then on long journeys the birds should be taken out, fed, and watered. There is no justification for the suffering caused. A law of nature compels us to kill in order to live, but there is no necessity for cruelty. In some countries there are especially constructed railway wagons for carrying poultry. These are well aired, and the wood is smooth and flat so as to avoid injury to the birds, while there are troughs for water and food that can be replenished from the outside. A large proportion of the poultry that is tortured for want of proper means of transport comes from Ireland. Some of the dealers do take good care of the birds, but they are in the minority. These humane and conscientious men are consequently placed at a disadvantage when competing with less scrupulous and more callous dealers. It would be an act of justice as well as mercy if the Act for the Prevention of Cruelty to Animals were extended to include birds. This reform would prevent much unnecessary and wasteful suffering in the animal world. Birds which have been injured, frightened, and exhausted by a long painful journey are less suitable for human food. Big cattle after a long railway journey, though not injured and much better cared for during transit, are generally given some three days in which to recover before they are slaughtered. If this is not done the quality of the meat is impaired. Why should not similar care be taken of live poultry?

INTRACRANIAL CEREBRAL HÆMORRHAGE IN THE NEWBORN RELIEVED BY OPERATION.

INTRACRANIAL cerebral hæmorrhage in the newborn, if it does not kill the patient forthwith, is acknowledged to be one of the common causes of congenital spastic paraplegia or Little's disease. In an analysis of 74 necropsies on infants still-born or dying in the first few days of life, Archibald found subdural hæmorrhage in 32 and extradural hæmorrhage in 5. It was the probable cause of death in most of these cases. Sometimes, as Löri has shown, minute multiple hæmorrhages (cortical and otherwise) occur, and for cases of this description little can be done by way of active interference. In the first group, however, surgical treatment has been tried in a fair number with varying success. In the *Boston Medical and Surgical Journal* (Jan. 11th, 1912), Dr. Channing C. Simmons, surgeon to the Massachusetts General Hospital, reports two cases successfully operated on. It is probable that more cases are operated on than are reported, for Dr. Simmons can find a record of only 14, with four recoveries—the latter cases operated on by Cushing, of Baltimore, and published by him. This seems a small proportion of successful cases, for which various causes may be advanced by way of explanation. The diagnosis ought to present no difficulties, at least in the majority of cases. As a rule, there is a history of prolonged and difficult labour, usually in a primipara. A few hours after birth the infant becomes stupid, has attacks of vomiting, may be unable to take the breast, and frequently begins to show symptoms of cortical irritation, with convulsive involuntary movements and possibly some stiffness of the limbs. In Dr. Simmons's first case the fontanelles were tense and bulging, and did not pulsate, while lumbar puncture was followed by the escape of blood-stained cerebro-spinal fluid. In this instance the technique was as follows. Wrapped in blankets, and surrounded by hot water bottles, the infant was given the merest whiff of ether, and then a short curved incision was made over the anterior fontanelle, which was bulging and bluish in colour. The coronal suture and underlying dura were then incised by a cut, about ¾ in. long, 1½ in. to the right of the median line. An ounce of dark blood at once escaped. The same procedure was carried out on the other side, when more dark blood came away. Thereafter the fontanelles became soft and commenced to pulsate normally. The infant made a good recovery, and 13 months later bade fair to develop into a normal, healthy child. It appears that in cases of this description the hæmorrhage usually occurs from one of the veins running upwards over the cortex to empty into the superior longitudinal sinus in the neighbourhood of the anterior fontanelle. If there is overlapping of the bones in a difficult labour one or other of these veins may be torn, when the blood will be extravasated, usually more or less over the motor area, and will gradually diffuse itself over the entire hemispheres. Should the motor area not be involved there may be no localising symptoms, but a history of difficult labour, and symptoms of cerebral compression in the shape of accelerated pulse, bulging fontanelles, shallow respiration, dilated pupils, and inability to take the breast ought to be a sufficient guide to the condition. Lumbar puncture is of great value as an aid to

diagnosis. Dr. Simmons attributes his good results to the simplicity of his procedure, and does not think an osteoplastic operation in the parietal region is called for unless the hæmorrhage is very large and has extended to the tentorium. It may be necessary to operate more than once, especially since organisation of an incompletely removed clot may give rise to irritative symptoms later in life. If the infant is moribund or in a critical condition Dr. Simmons's procedure should be tried without delay, and if it prove unsatisfactory an osteoplastic operation might follow. With the good results obtained by Cushing and by Dr. Simmons in view, it is incumbent on the obstetrician to recognise the condition and to seek surgical aid at the earliest possible moment, for otherwise there can be, in all probability, only one or other unfortunate ending—either the infant dies or he suffers from infantile hemiplegia, Jacksonian epilepsy, or spastic paraplegia in later years.

THE PHYSICIAN AND THE PATHOLOGIST ON HEART FAILURE.

AN interesting debate by the Chelsea Clinical Society on Disorders of the Circulatory System was opened on March 12th with a paper by Sir T. Clifford Allbutt, entitled "The Physician and the Pathologist on Heart Failure." Professor Allbutt showed how the two aspects of cardiac failure, the clinical and the pathological, are lacking at present in correlation, and he suggested that if the workers in these fields would coöperate more the complications and uncertainties of the subject might be cleared up. He dwelt on the misleading nature of various physical signs in heart failure unassociated with valvular disease; nevertheless, persistent alteration of pulse-rate and the phenomenon of pulsus alternans are, in his view, each very suggestive of myocardial damage, although neither is an absolute criterion. Professor Allbutt in particular surveyed the problem of sudden death without previous signs of illness in the man who does not suspect that he is ill. His interesting and thoughtful paper was followed by remarks from Sir Lauder Brunton and Dr. Samuel West, who both inclined to the view that the explanation of such cases is a toxic one, and the debate was continued by Dr. Hector Mackenzie, Dr. C. C. Gibbes, and others. We hope to publish an account of the discussion in our next issue. On March 19th the clinical debate will be continued at the Physiological Laboratory of the University of London, Imperial Institute, S.W., when Professor Wilhelm Einthoven, M.D., of Leyden, will read a paper on "The Various Forms of the Human Electrocardiogram and their Significance." The meeting is open to the whole of the medical profession.

THE DEVELOPMENT OF THE PARASITE OF INDIAN KALA-AZAR IN CIMEX ROTUNDATUS AND CIMEX LECTULARIUS.

Captain W. S. Patton, I.M.S., who has been deputed by the Government of Madras to carry out further investigations into the etiology of kala-azar, has been able by feeding Cimex rotundatus and Cimex lectularius on a case of kala-azar, in whose blood there were a large number of parasites, to discover its complete development. This discovery was foreshadowed in a telegram published in these columns on Feb. 17th last. The parasite has been followed from its unchanged state in a leucocyte through the flagellate stage up to the rounding-up of the parasite into its post-flagellate form, as was predicted in 1907.[1] The further important discovery was made that if bugs which already contained the developmental forms were again fed on another case of kala-azar in a monkey (Macacus sinicus) the flagellating forms were completely destroyed within 24 hours; whereas if the bugs were not fed again the development goes on and is completed by the tenth, eleventh, and twelfth day after the single feed. This discovery at once explains why in all the previous experiments he was never able to obtain massive infection of the bug or to get its complete life-history, for the simple reason that the bugs were then repeatedly fed on the case and not kept long enough after their last feed.[2] It further suggests an explanation why the disease does not readily spread outside the endemic area, as this material obstacle prevents many bugs from becoming infective. These recent observations clearly demonstrate that in Cimex lectularius, the European bed-bug, the parasite goes through its complete development as readily as in Cimex rotundatus, and that by the seventh, eighth, and ninth day this bug swarms with flagellate stages in masses of rosettes. It is very probable then that the parasite of infantile kala-azar known now to occur along the Mediterranean littoral also undergoes its development in Cimex lectularius. Captain Patton has further found that in Conorrhinus rubrofasciatus, the bug suspected by Donovan, which was bred from the eggs and fed on the case, the parasite degenerates and never flagellates; this finally proves that this bug has nothing whatever to do with the transmission of kala-azar. All the bugs used in these experiments were bred in the laboratory and had their first feed on the case. Cimex lectularius was obtained from the slums of London, and like Cimex rotundatus it never contains a natural flagellate. A memoir describing the observations particularly of the post-flagellate stage will shortly be published.

THE LESION CAUSED BY JUDICIAL HANGING.

IT is an old saying that there are more ways of killing than by hanging; but perhaps it is not so well known that there are many different ways of killing by hanging. When a criminal is hanged he dies a practically instantaneous death, but his death may be brought about in a strange variety of ways. From the medico-legal point of view more attention has been paid to the results produced by the methods of the suicide than to the actual state of affairs which brings about the death of a man executed in the interests of justice. And yet, since hanging is the accepted English method of despatching the criminal, any evidence of the processes by which death is brought about cannot be unimportant. It must be admitted at once that the term "hanging" is not at all a good one to express the mode of death in a modern execution. Hanging suggests the passive suspension at the end of a rope, and seems to connote a throttling of the victim by the drawing tight of the noose. Suicides do literally hang themselves, and in olden days men were hanged when executed, death from apoplexy or asphyxia being caused by the constriction of the neck. But something more than this comes into play in a modern execution, for the jerk of the drop, and not the running taut of the noose, is the factor which in most cases brings about an instantaneous death. The criminal is not throttled to death, but a sudden jerk imparted to the base of his skull kills him with a surprising suddenness. Exactly what this jerk does depends on many things, such as the length of the drop and the position of the knot, and totally different results are found in different cases. At times no injury to the bones of the neck can be found after death, and in these cases it is probable that a general stretching of the ligaments has permitted a fatal injury to the cord without producing any bony lesion; it is even possible that some of the more subtle causes of death, which are seen in the suicide,

[2] Vide Memoirs Nos. 27 and 31.

come into play. It has been thought that the odontoid process became torn from its ligaments, and so crushed the cord; it has even been said that some executioners could produce this result at will by giving a rotary motion to the falling body. Still, although this is a common belief concerning hanging (and certainly one case of damage to the odontoid is recorded), it is probably a somewhat rare accident for death to be brought about by injury of the cord due to a fractured, or liberated, odontoid process. Almost any degree of injury to the cervical region of the spine may be produced. The third cervical vertebra is the one most commonly fractured, but the extent of injury may range from a mere tearing of the ligaments, or a slight fracture of the bone, up to a complete severance of all the tissues of the neck. Complete decapitation has been produced by a drop of no more than 9 feet. Apart altogether from this lesion of the cervical vertebræ a strange injury to the skull has been described, and it seems certain that an executed man may die as the result of extensive cranial injuries, whilst his cervical vertebræ remain intact. The anatomists engaged in the archæological survey of Nubia had the opportunity of examining the bodies of over a hundred men, all of whom had been executed in Roman times, and some of whom still carried round their necks the ropes with which they were hanged. These men showed no lesion of their cervical vertebræ, but the sutures of their skulls were torn open in such a manner as to lead Dr. F. Wood Jones to suppose that the knot, catching on the angle of the jaw, had tended to pull one temporal bone and the facial part of the skull bodily upwards from the occipital and the base of the skull. These lesions were remarkably constant in the Nubian series, although the skulls of several men known to have been hanged, which are lodged in various museums, did not show any such injury. Quite recently the demolition of the old buildings in Jail-square, Glasgow, has provided Dr. G. H. Edington with the opportunity of examining and describing[1] the skull of Dr. Pritchard who was hanged for his crimes on July 28th, 1865, before a crowd of 100,000 onlookers. The circumstances of Pritchard's hanging are fairly well known: Calcraft, the advocate of the Scottish "short-drop" method, was the executioner, and a fall of between three and four feet was allowed. This drop does not appear to have been sufficient, for it "was only after Calcraft went below and pulled the legs that the body was brought to stillness." The degree of force used by Calcraft is, of course, a matter for conjecture, but the interest of it lies in the fact that the lesion produced by this added pull is exactly similar to that found in the skulls of the Nubian natives executed by the Romans. Pritchard had his right temporal bone disrupted from the skull, and, although there is no external evidence on the point, it is probable that the knot of the rope was on the right side of the neck. Different executioners place the knot in different positions, and it seems certain that with the knot under the chin a lesion of the cervical vertebræ is likely to be produced; while with the knot under one ear a cranial lesion may well result, and such a lesion is but a very exaggerated form of the boxer's "knock-out blow." It is not at all impossible that this exaggerated knock-out blow may prove to be *the* cause of death in modern judicial hangings in which the knot is placed under the ear.

WE are glad to announce that the Lord Mayor of London, Sir Thomas Crosby, M.D., after an investigation made by himself personally, has reported to the Council of the Metropolitan Hospital Sunday Fund that the amount expended by St. George's Hospital upon the bacteriological and pathological departments was not excessive, and was properly taken from the general funds of the charity, being for the direct treatment of the patients. Presumably the usual grant to St. George's Hospital from the Fund will be forthcoming.

THE relatives of the late Lord Lister wish through us to offer their sincere thanks for the many letters and messages of sympathy which they have received from public bodies and from private individuals in this country and abroad, and to express their appreciation of the honour which has thus been rendered to his memory. They make this acknowledgment, fearing that some of these messages may inadvertently remain without particular answers.

Lord Esher has announced to the Vice-Chancellor of the University of Cambridge that an anonymous benefactor has placed in his hands £20,000 for the endowment of a professorship at Cambridge in connexion with the experimental study of heredity and of development by descent. The donor stipulates that the new chair shall be called "the Balfour Professorship of Genetics" in honour of Francis Balfour, and that the first appointment shall be made jointly by the Prime Minister and Mr. Arthur Balfour.

Dr. H. R. D. Spitta, assistant bacteriologist to St. George's Hospital, has made a report, at the request of the Postmaster-General, upon the possibility of the communication of tuberculosis through the use of telephones, and finds the danger to be non-existent.

ON the occasion of the opening of the University of Hong-Kong on March 11th, the King signified his intention of conferring the honour of knighthood upon Dr. Ho Kai, C.M.G., who has taken a prominent part in the movement for the establishment of the University.

THE Lumleian lectures on "Some Moot Points in the Pathology and Clinical History of Pneumonia," which were to be delivered by Dr. Percy Kidd on March 21st, 26th, and 28th, before the Royal College of Physicians of London, are unavoidably postponed until May 30th and June 4th and 6th.

WE regret to announce the death, on March 12th, of Sir Richard Brayn, Home Office Expert in Lunacy and formerly medical superintendent of Broadmoor Asylum.

ASSOCIATION OF CERTIFICATED DISPENSERS.—The sixth annual meeting of this association was held at the Apothecaries' Hall, Blackfriars, London, E.C., on March 7th, Mr. Montagu Smith, Lewisham Infirmary, presiding over the largest gathering that has yet assembled for the annual convention. The annual report showed a steady increase in the membership, large numbers having joined for protection against the unsettling tendencies of the National Insurance Act. The constant care of the committee and honorary secretary (Mr. A. Howell, Dalton Dispensary) had been to see that the interests, rights, and privileges of the members were secured in the Act. Every member of the House of Commons had been circularised. Deputations had been received by influential members of the Government, resulting in a special clause being added to the dispensing clauses for the benefit of holders of the Hall certificate. A petition had been forwarded to the Privy Council with reference to powers given to the Pharmaceutical Society under Section 4, Sub-Clause B, of the Poisons and Pharmacy Act, 1908, and a Bill proposed by the Society of Apothecaries with the object of bringing the certified dispenser into line with modern requirements will be submitted to Parliament at an early date.

ANNUAL REPORT OF THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD.[1]

COMPARATIVELY slight acquaintance with the recent progress of preventive medicine will serve to correct the erroneous impression that this science is exclusively concerned with the study of infectious disease. Nevertheless, the history of past epidemics conclusively shows that very much of the suffering and loss of health, as well as of the poverty and distress endured by the poor of this country, has been caused by the ravages of one or other of these pestilences. Argument is not needed to show that it is by investigation of the causes of these conditions, by which means alone the best methods for their suppression can be discovered, that the study of this particular branch of preventive science is likely to prove serviceable to the State.

These remarks are suggested by the perusal of Part II. of Mr. John Burns's recently issued presidential report, the first part of which we have already reviewed.[2]

Some Historical Remarks.

Before commenting on the volume before us we may usefully observe that under the Act of 1871 the Local Government Board first became responsible for the discharge of the few sanitary functions which had previously been performed by the Privy Council Office, for which purpose Sir John (then Mr.) Simon was transferred to the Board from the staff of the Privy Council office, under the title of principal medical officer. In the course of the last 40 years many other administrative duties have been allotted to the Board, which has, therefore, become the controlling State authority for the public health service of the country.

Not until many years after the establishment of civil registration in 1837 was serious attempt anywhere made to ascertain the actual amount of damage done by infectious disease in this country beyond what could be gathered inferentially from the mortality caused thereby. In the course of the second half of last century certain of the more enlightened municipalities obtained powers under local Acts for the compulsory reporting of such diseases, although the information so obtained was restricted to local purposes. Nothing of the nature of interchange of this information among protected towns was attempted until early in the "eighties," when a provincial medical officer of health started the experiment of collecting returns of infectious sickness from notification towns and distributing weekly lists of the former among the collaborating authorities. The success of this experiment having been established, the Local Government Board was eventually persuaded to undertake the publication of the returns, which were daily becoming more valuable as the policy of protection became more general among the municipal authorities. Since the passing of the Infectious Diseases Notification (Extension) Act, which made notification generally compulsory, the registration of infectious sickness has become gradually more complete, and for several years past the tabulation and circulation of the returns have been carried out periodically by the Local Government Board, as all who have read our columns regularly know.

Case Mortality of Infectious Diseases.

In the supplement to this report, already noticed in THE LANCET of Nov. 25th, 1911, Dr. Newsholme dealt with notification from the medical standpoint; here the President treats of it mainly from an administrative aspect. Attempts are sometimes made to ascertain the "fatality" or case mortality of infectious attacks by comparing the registered deaths with the reported cases in a given area; but in other than exceptional circumstances this practice may lead to erroneous conclusions. By comparing the cases and deaths from particular diseases in the country as a whole the danger of error is of course reduced; and a table appears in this report showing the ratio of deaths to notified attacks in the year 1910. From this it appears that out of nearly 72,000 notified cases of scarlet fever in England and Wales only 2·3 per cent. died. Among nearly 7000 cases of enteric fever the fatality was 17·8 per cent., whilst among 25,000 cases of diphtheria it was 10·2 per cent. The sanitary authorities both in London and in the provinces are now empowered to distribute diphtheria antitoxin gratuitously for the treatment of their poorer inhabitants, and, whether or not this has been helpful, it is satisfactory reading that ever since the year 1906 diphtheria in this country has steadily declined.

Pulmonary Tuberculosis.

The temporary powers granted to four large towns for including tuberculous phthisis among notifiable diseases expired in 1910. Mr. Burns now expresses the opinion that "the addition of phthisis to the list of diseases notifiable under the general Act carries with it certain disabilities to persons suffering from the disease which should not be attached to all persons suffering from phthisis." Nevertheless, in view of the fact that the principal disabilities have been removed, the Board has extended the operation of these powers in the cases referred to for a further period of ten years. By the Local Government Order of 1908 tuberculosis was made compulsorily notifiable in all Poor-law institutions, and in 1910 the system was extended to patients in hospitals and dispensaries. In November, 1911, a further extension was made so as to secure the general notification of phthisis. In more than 280 districts a system of voluntary notification of tuberculosis is in operation, and that system is rapidly spreading, perhaps in connexion with the tuberculosis regulations of 1908 above referred to. For the accommodation of phthisical patients some authorities make provision in sanatoriums. Certain dispensaries also render useful aid by undertaking the diagnosis of disease and the selection of cases for sanatorium treatment. Moreover, the Board is disposed to sanction the provision by local authorities of open-air shelters for the care and treatment of sufferers from this disease. The appearance of the section in the recent National Insurance Act may be thus accounted for.

Exotic Disease.

Under the head of Exotic Disease it is stated that the Local Government Board has continued to give advice and information concerning questions of infectious diseases in the colonies and in foreign countries. Pneumonic plague is reported to have occurred in four instances during September, 1910, in East Suffolk, the circumstances of which were investigated by the late Dr. Bulstrode.[3] With these exceptions no suspected cases of human plague occurred during the year. A report has recently been issued by the Board containing an account of the investigations undertaken in connexion with the plague epizootic. These investigations are still proceeding. Asiatic cholera prevailed extensively during the year 1910 in parts of Russia, and the riparian sanitary authorities trading with Russia were warned to be on their guard against importation of infection into their districts by vessels coming from possibly infected places. Fortunately, no cases of the disease are known to have occurred in this country during the year.

Order relating to Medical Officers of Health.

In the present volume certain important changes are foreshadowed in public health procedure which, in the aggregate, amount to a new departure. Considerations of space compel us to limit our review to changes having definite interest for our profession. The Board has issued a new Order, which came into force at the beginning of 1911, and which was accompanied by a memorandum specifying, *inter alia*, the particulars in which the duties of medical officers of health are affected by the Order. Whilst recognising the value of the work of many health officers engaged in private practice, the Board is of opinion that the holding of such appointments by practising medical men is now undesirable. The President suggests the expedient of combining several small districts under the care of a highly qualified medical man who should be debarred from private practice, as are the county medical officers recently appointed, but who may advantageously hold such an appointment as that of education medical officer, isolation hospital superintendent, certifying factory surgeon, police surgeon, or public vaccinator.

In regard to tenure of office by medical officers of health

[1] Fortieth Annual Report of the Local Government Board, 1910-11, Part II. Wyman and Sons. Price 1s. 10d.

[2] THE LANCET, March 2nd, 1912, p. 601.

[3] THE LANCET, Sept. 2nd, 1911, p. 697.

the Order makes certain alterations which, in some respects, appear to be improvements. In addition to the duties prescribed by the Board's Order of 1891, every medical officer of health is now required to despatch weekly to the Local Government Board, and to the medical officer of the county, a return of the cases of infectious disease notified in his district during the previous week. From these returns a statement is compiled at Whitehall, which is circulated to every medical officer of health in England and Wales, and which shows the number of infectious cases notified in each district during the preceding week. This change is associated with, and is made practicable by, a corresponding change in the form in which the Registrar-General will present the vital statistics of the kingdom from the year 1911 onwards. In our issue of Jan. 13th, 1912, p. 106, we referred to this salutary rearrangement, which involves the substitution of sanitary for Poor-law districts, so that the data collected by the local authorities will in future correspond nearly to those published by the Registrar-General.

Milk-supply.

Cow's milk is still very frequently found to be the medium of dissemination of enteric fever and other infectious diseases; and for this reason the arrangements locally in vogue for its distribution demand the constant vigilance of sanitary authorities and their officers. In England and Wales there are still 144 sanitary authorities that have not adopted the Board's regulations for securing the purity of the milk-supply. The amount of adulteration detected in milk samples analysed during the year is given in a table, and varies considerably in different districts. Of the total of 47,895 samples examined 11·1 per cent. were found to be adulterated. The favourite substance used for the preservation of milk and cream appears to be boric acid. More than 160 local authorities have already made arrangements for the veterinary inspection of milch cows in their districts, and many other authorities have obtained power under local Acts to stop the supply in their districts of milk from a dairy outside their district in which there has been detected a cow with tuberculous disease of the udder. Having regard to the latest pronouncement of the Royal Commission on Tuberculosis it is of the first importance that similar powers should be conferred by general legislation on all sanitary authorities, who should be held responsible for the due enforcement of those powers.

Water-supply.

The maintenance of the public health so greatly depends on the purity of the water-supply that its constant supervision by the medical officer of health is made a special duty under the Board's recent Order. Thus, he is required to report "as to the sufficiency and quality of the water-supply of his district and of its several parts; and in areas where the supply is from waterworks, as to whether the supply is constant or intermittent." Moreover, he is required to furnish a report as to the pollution of rivers and streams in his district. In view of the fact that many river waters are liable to serious pollution, especially after heavy rain, the latter requirement is vitally important. In the course of the year the Board corresponded with several local authorities in consequence of complaints of defective water-supplies, insisting, in certain cases, on the removal of dangerous conditions.

Inspection of Meat.

In connexion with the supervision of the foreign meat-supply in the interests of the public health at home, the Board's attention was drawn during the year to the presence of a parasitic worm in the frozen quarters of meat arriving here from Australia, the resulting pathological condition being known as onchocerciasis.[4] In order to deal effectively with onchocerciasis in Australia the Commonwealth Government has made satisfactory arrangements for inspection of meat before export to this country. Chinese pork is now imported here in increasing amount; large consignments of Chinese pigs imported at Liverpool were examined during the year, and were found to comply with the official regulations, and as regards the Chinese farms in which the pigs are reared, Dr. R. A. Farrar reports, as the result of personal inspection, that their condition is generally satisfactory. The preservative treatment of imported meat by means of formaldehyde was made the subject of investigation during the year. The question of the suitability of this chemical for preservative purposes is dealt with in a report issued by the Board in 1909.[5]

Canal Boats.

Only a few years ago the influence of the canal-boat population as disseminators of infectious disease was generally considered dangerous to the communities dwelling on the canal banks. But in recent years the canal traffic has been steadily declining, the number of inhabited boats in use having consequently decreased. The dwellers in these boats are kept under better supervision than formerly, and a recent report speaks appreciatively of the coöperation for this purpose of the sanitary authorities concerned. Nevertheless, in some places canal-boat inspection is still perfunctory, the boats being simply observed from the canal banks or the numbers copied from the entries of previous years. Only 26 cases of infectious disease have been reported on board the 9121 boats used as dwellings during the year—viz., 8 of diphtheria, 5 of scarlet fever, 3 of erysipelas, 9 of enteric fever, and 1 of puerperal fever.

[4] THE LANCET, Feb. 4th, 1911, p. 317.

[5] Foods Report, No. 9, by Dr. Buchanan and Dr. Schryver.

THE RADIO-ACTIVE PROPERTIES OF THE WATERS OF BATH.

IT was suggested in an article in THE LANCET of Jan. 30th, 1904, that the fact that the Bath waters were found to be radio-active might lead to a more satisfactory explanation of the favourable action of natural mineral waters in hydrotherapeutic practice, and further inquiry has shown that the suggestion was a sound one. The presence, at all events, of salts which are of common occurrence, such, for example, as the sulphates and carbonates of calcium and sodium and chloride of sodium in small quantities, can hardly be referred to as accounting for the reputation of many natural waters in the treatment of disease.

At a meeting held in the Grand Pump Room at Bath on March 11th Sir William Ramsay gave an interesting and lucid account of his recent investigations into the characteristics of Bath waters before an audience composed chiefly of local medical men, with the Mayor, Mr. Alderman T. Forder Plowman, J.P., in the chair, supported by the city councillors. Referring to the analyses of the Bath waters made in 1899 in THE LANCET Laboratory, Sir William Ramsay said that there are undoubtedly mineral waters which owe their curative power to what may be termed ordinary chemical ingredients. Such were, for instance, sulphur waters, ferruginous waters, arsenical waters, and possibly lithium waters; but the recorded analyses of the Bath waters show, in the main, merely ordinary constituents, most of which are present in many drinking waters. "Sulphates of calcium, of sodium, of potassium, carbonates of calcium and magnesium, are all common substances, and the only unusual constituents of Bath waters, so far as the analysis made at THE LANCET Laboratory shows, are small quantities of strontium, of lithium, and a trace of bromine." The fact, however, that many mineral waters all over Europe have for ages been used for curative purposes, combined with our present knowledge that such waters, while not remarkable in "chemical" composition all agree in yielding helium, the product of decay of radium, makes it of particular interest to examine these waters for niton, the radium emanation, as well as for radium itself. Investigation, he continued, showed that the Bath waters are relatively rich in niton, showing an effect equal to the activity of 1·73 milligrammes of radium in a million litres. The gases evolved, moreover, contain also a relatively enormous amount of neon.

It is quite clear from these experiments that the Bath waters must possess marked radio-active properties, and a very simple observation, only recently interpreted rightly, in our opinion confirms this view. For a very long time it has been noticed that in the drinking glasses in which the Bath mineral waters have been served a uniform discolouration of the glass sooner or later takes place. In fact, when the water is left in contact with the glass for merely a few weeks the discolouration is very marked, the vessel becoming of a greenish-yellow hue. This was thought to be a deposit of iron on the glass, but it is now

shown to be due to the action of radio-active substances, just as some windows facing to the south assume an amethyst tint by the action of the rays of the sun. In the former case the greenish-yellow colour is probably due to some separation of lead, while in the latter the amethyst tint is due to traces of manganese in the glass.

Sir William Ramsay further pointed out that in conjunction with Dr. A. C. Stevenson at University College, he had conducted experiments in which mice were fed with bread and cheese soaked in a solution of niton and in which kittens were injected with a similar solution, as well as fed with it. In this way it was shown that the niton is got rid of chiefly by the lungs, and that in about three hours. After 12 hours all traces have disappeared. It may be that when a patient takes a bath the skin absorbs some niton; and some undoubtedly enters the lungs, for it is continually being given off from the surface of the hot water. Assuming this to be the case, he asked whether there is any means of increasing the dose taken by each of these methods of absorption. Skin absorption could be increased by placing the patient in the electric bath, connecting him with the negative pole of a battery and placing the positive electrode in the water. Since niton in disintegrating is continuously discharging electrons, or, in the older phraseology, losing negative electricity and becoming positively charged, the emanation would be attracted by a negatively charged body, and the niton would thus rapidly reach the skin. It would most likely, indeed, enter the system by ionisation. Experiments on these lines would require to be made with caution, but it is not probable that a dangerous dose would accrue when the waters of Bath were employed, since the amount of niton in an ordinary bath-full of water would be small. If desirable, Sir William Ramsay suggested, much larger doses of niton could be administered by using the gases together with spray directly against the skin, and it is conceivable that such an administration might prove efficacious in the treatment of local rheumatism. Care would have to be exercised in using this mixture as a spray in breathing, as absorption by the lungs would no doubt be very rapid.

At the termination of the address, which was followed with the greatest interest, a vote of thanks to Sir William Ramsay was proposed by Alderman C. Bryan Oliver, J.P., chairman of the Hot Mineral Baths Committee, who said that Sir William Ramsay had undertaken the investigation voluntarily and purely from a scientific point of view. Dr. R. J. H. Scott seconded the proposal, which was supported by Sir James Mackenzie Davidson, who referred to researches which had shown that treatment by radio-active mineral waters appeared to diminish uric acid production and had been used with distinct relief in rheumatic cases. He regarded, however, the whole question as being in the melting-pot, further investigations being needed if the method was to escape the reproach of empiricism.

We understand that the results of Sir William Ramsay's investigation are considered by the members of the corporation to be of such far-reaching importance as to justify them in making fresh financial proposals in order to develop the facilities for treatment by the thermal waters of Bath in the direction indicated.

PRESENTATION TO MR. F. T. PAUL.—A dinner will take place at the Exchange Hotel, Liverpool, on Wednesday, March 27th, at which it has been arranged to present to Mr. F. T. Paul his portrait, painted by Mr. Hall Neale. This has been subscribed for by Mr. Paul's friends and colleagues on his retirement from the active surgical staff of the Royal Infirmary. Those desirous of being present at the dinner are requested to communicate with one of the honorary secretaries—Mr. T. C. Litler Jones, 1, Abercromby-square, and Dr. Hubert Armstrong, 7, Rodney-street, Liverpool.

MEDICAL MAN FINED IN AN X RAY CASE.—A Bavarian practitioner has been fined £4 for causing bodily damage to a patient whom he was treating by means of Roentgen rays. It seems that he left the room for a few moments, previously enjoining the woman to lie quite still and not to move. Disobeying him, however, she shifted her position and received slight burns on the tip of the nose, the chin, and the chest. The court decided that the medical man was to blame for having absented himself without turning off the current.

MEDICAL AND SANITARY ADMINISTRATION IN THE GERMAN COLONIES DURING 1909-1910.[1]

THE annual medical reports upon the German colonies increase in interest and importance, while the amount of material comprised in them grows larger year by year. The report for the fiscal year beginning April 1st, 1909, and ending March 31st, 1910, has now been issued and contains twice as much printed matter as that issued four years ago. It is regrettable that the report should be so belated, though valuable lessons may be drawn from it none the less.

Germany's possessions outside Europe are divided into two groups—(1) those situated in Africa and (2) those in Oceania; the former include the colonies of German East Africa, the Cameroons, Togoland, and German South-West Africa, while the second group consists of German New Guinea, the Caroline Islands, the Marshall Islands, the Marianne or Ladrone Islands, and Samoa. A medical report on each of these colonies is included in the volume for 1909–10, with the exception of South-West Africa, as to which, for some unexplained reason, no report is given on the present occasion.

German East Africa.

The most important of Germany's extra-European possessions is the colony of East Africa, which has an estimated population of 7½ millions, the report upon it filling 246 pages out of the total 649 comprised in the present annual volume. The details contained in it may therefore be taken as a sample of the other reports, which, however, are naturally not quite as full of detail. The medical staff employed in East Africa is about 100, but even this number was reduced by a fifth during the year owing to home leave and other causes; moreover, the routine medical work was further interfered with by some members of the staff being detailed for special duty in connexion with measures directed against prevalent diseases such as small-pox, plague, malaria, ankylostomiasis, and sleeping sickness.

Vaccination and Small-pox.

The value of vaccination is now recognised by the natives of East Africa, who gladly accept the protection offered by it. Small-pox was prevalent during the year, particularly in the proximity of the new railway line now in process of construction. The cases officially reported numbered 860, and of these 234 died, giving a case-mortality of 27·2 per cent. It is probable that other cases were not reported, especially in localities where no medical officer or official was stationed. Nearly 900,000 vaccinations were performed during the year, about 81,000 of which were revaccinations, the successful results being about 73 per cent. of the whole.

Hitherto vaccine lymph has been obtained from Hamburg, and although this, owing to certain precautions taken during the voyage, was found quite active on its arrival, it rapidly deteriorated during transit into the interior. The plan now followed is to vaccinate calves with the Hamburg lymph as soon as it reaches the Port of Daressalam, the fresh calf lymph thus obtained being dispatched up country to the various stations, where again other calves are inoculated with the Daressalam lymph, and from these latter calves a supply is produced for vaccination of the natives of each district. In this way some 13 lymph producing stations in addition to that at Daressalam are now able to afford a copious supply of fresh and active lymph at a comparatively small cost. It is well known that local strains of vaccine lymph tend to lose their virulence in time; in order, therefore, to start a new strain calves at two stations (and also a sheep) were successfully inoculated with human variolous matter. At one station where goats had similarly been inoculated it was found, however, that calves could not be successfully vaccinated from them. Question also arose as to the identity of African and European small-pox, and whether vaccination by European lymph conferred protection against African small-pox or *vice versâ*. After due investigation by members of the staff it was decided that the disease, as it appears in Europe

[1] Medizinal-Berichte über die Deutschen Schutzgebiete, für das Jahr 1909–10 (Medical Reports upon the German Colonies for the year 1909–10), edited by the Imperial Colonial Office. Published by Ernst Siegfried Mittler und Sohn, Berlin. 1911. Pp. 649, with 45 illustrations in the text and 13 reproduced photographs. Price 11 marks bound, and 10 marks unbound.

and Africa, is identical, and that vaccination with African lymph conferred protection in either case. It is worth mention that vaccine lymph is purchased from the German Institute at Daressalam by the British authorities at Zanzibar for use in that territory.

Plague.

Though plague was prevalent in the previous year at Daressalam, it did not recur during 1909–10; nevertheless, measures were continued with a view to prevent its spread. Over 28,000 rats were destroyed, and of these 10,192 were examined in the laboratory without any infected animal being found. The experiment was tried of keeping domestic cats, but the native cat takes no trouble to hunt for rats, nor was the substitution of Egyptian cats attended with any better success. The best arrangement was found to be the employment of skilled rat-catchers giving their whole time to the work. Up country plague appeared in two districts, Muanza and Kondoa-Irangi, in both of which places a simultaneous epizootic among rats was observed. Over 132 persons were reported as attacked by plague, the infection having, it is alleged, been introduced from Port Florence (in British territory) into Kondoa-Irangi, though it is admitted that plague has been endemic in Muanza for many years.

Malaria and Blackwater Fever.—Ankylostomiasis.

Malaria and blackwater fever are responsible in East Africa for a third of all reported sickness and deaths. Anti-mosquito measures, more especially in the coast towns, were actively carried out, and search was made to discover carriers of the parasite. In Tanga alone 13,704 persons were specially examined, and in the blood of 5837 of them the malarial parasites were found; and of 560 Europeans, none of whom had obvious illness, 66 were discovered with parasites in their circulation. As regards children with splenic enlargement, 787 out of 1130 examined were positive—that is, 70 per cent. An increased rainfall was associated with greater prevalence of malaria during the year. In towns—such as Daressalam—the number of dwellings in which the doors and windows are screened with wire gauze is becoming larger each year, and in the native huts the use of mosquito nets at night is getting more general. On the other hand, it cannot be denied that the number of Europeans who habitually neglect quinine prophylaxis is on the increase.

Ankylostomiasis has considerable influence upon the sickness and mortality among the natives of the colony, and on economical grounds its suppression is very desirable. In two districts the respective medical officers examined the stools of altogether 10,150 persons, and of these 4188 were found infected. The campaign against ankylostomiasis includes the distribution gratuitously of leaflets in German and Swaheli, giving a short account of the way the disease is spread and how it can be prevented. Regulations for providing proper and sufficient latrine accommodation are enforced, as also measures for protection of domestic water-supplies. The stools of all suspected cases are microscopically examined, and appropriate treatment is given to all found to be infected.

Sleeping Sickness.

Sleeping sickness is prevalent in two parts of the colony, on the shores of the Victoria Nyanza and along the banks of Lake Tanganyika. A sum of rather more than £12,000 was expended in the campaign against the disease during the year. The plan of interning all persons suffering from sleeping sickness in camps was not pressed on account of the grave objections made to it by the natives, but steps were taken, where practicable, to remove the threatened population from the fly-infected regions to other fly-free areas, as has been done in Uganda by the British authorities. Efforts were made also to cut down bush and undergrowth near water where the glossina palpalis makes its haunts and breeding places. The drugs used in the treatment of the sleeping sickness cases were atoxyl, arsenophenylglycin, arsacetin, mercury, &c., alone or in combination, the two first-named giving, perhaps, the best results.

It is evident from the extracts we have quoted that in East Africa, as well as in the other colonies of Germany, the treatment and prevention of disease are carried out by the most modern methods. The economic development of these possessions, rapidly progressing, notwithstanding all the hindrances arising from endemic tropical disease, need not therefore surprise us.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

CANADIAN REPRESENTATIVES.

THE following nominations have been received from the Canadian National Committee in response to the invitation sent them by the Organising Committee:—

Executive Committee.—Dr. Alexander McPhedran, Toronto; Dr. W. H. B. Aikins, Secretary of the Canadian Committee, Toronto.

Organising Committee.—Dr. George Armstrong, Montreal, President of the Canadian Medical Association; Dr. C. K. Clarke, Dean of the Medical Faculty, University of Toronto; Dr. J. C. Connell, Dean of the Medical Faculty, Queen's University, Kingston; Dr. H. H. Chown, Dean of the Medical Faculty, University of Manitoba, Winnipeg; Dr. E. P. Lachapelle, Dean of the Medical Faculty, Laval University, Montreal; Dr. F. J. Shepherd, Dean of the Medical Faculty, McGill University, Montreal.

Section I.—Anatomy.

Council.—James Playfair McMurrich, M.A., Ph.D., Professor of Anatomy, University of Toronto.

Section II.—Physiology.

Vice-President.—Thomas Gregor Brodie, M.D., F.R.S., Professor of Physiology, University of Toronto.

Council.—Archibald Byron Macallum, M.A., M.B., Ph.D., Sc.D., LL.D., F.R.S., F.R.S.Can., Professor of Bio-Chemistry, University of Toronto; Swale Vincent, M.D., D.Sc., F.R.S. Can., Professor of Physiology, Manitoba University.

Section III.—General Pathology.

Vice-President.—J. G. Adami, M.A., M.D., LL.D., F.R.S., F.R.S. Ed., F.R.S. Can., Professor of Pathology, McGill University.

Council.—John Joseph Mackenzie, B.A., M.D., Professer of Pathology and Bacteriology, University of Toronto.

Section III. (a).—Chemical Pathology.

Council.—John Beresford Leathes, B.A., M.B., B.Ch., F.R.C.S., Professor of Chemical Pathology, University of Toronto.

Section IV.—Bacteriology and Immunity.

Council.—Alfred H. Caulfield, M.B., Director of the Pathological Department, National Sanatorium Association, Gravenhurst, Ontario; Gordon Bell, M.D., Bacteriologist for Manitoba, Professor of Bacteriology, Manitoba University.

Section V.—Therapeutics.

Vice-President.—A. C. Blackadder, B.A., M.D., Professor of Pharmacology and Therapeutics, McGill University.

Council.—Velyien Ewart Henderson, M.A., M.B., Associate Professor of Pharmacy and Pharmacology, University of Toronto.

Section VI.—Medicine.

Vice-President.—A. McPhedran, M.D., Professor of Medicine, University of Toronto.

Council.—Harry Bertram Anderson, M.D., C.M., Associate Professor of Clinical Medicine, University of Toronto; F. C. Finley, M.D., Professor of Medicine and Clinical Medicine, McGill University; H. A. McCallum, M.D., M.R.C.P., Professor of Clinical Medicine, Western University, London, Ontario; James Third, M.D., Professor of Medicine, Queen's University, Kingston, Ontario.

Section VII.—Surgery.

Vice-President.—F. J. Shepherd, M.D., Professor of Anatomy, McGill University.

Council.—Irving Howard Cameron, M.B., F.R.C.S., Professor of Surgery and Clinical Surgery, University of Toronto; J. Alex. Hutchinson, M.D., Associate Professor of Surgery and Clinical Surgery, McGill University; O. M. Jones, M.D., Victoria, British Columbia; Eugene St. Jacques, M.D., Director of the Course of Pathological Anatomy, Laval University, Adj. Professor of Clinical Surgery; John Stewart, M.B., C.M., Emer. Professor of Surgery, Dalhousie University, Halifax, New Brunswick; H. T. Williams, M.D., F.R.C.S., Ass. Professor of Clinical Surgery, Western University, London, Ontario.

Section VII. (b).—Anæsthetics.

Council.—Robert A. Stevenson, M.D., Toronto; Samuel Johnston, B.A., M.D., C.M., Demonstrator in Anæsthesia, University of Toronto.

Section VIII.—Obstetrics.

Vice-President.—Adam Henry Wright, B.A., M.D., Professor of Obstetrics, University of Toronto.

Council.—J. C. Cameron, M.D., Professor of Obstetrics and Diseases of Infants, McGill University.

Section IX.—Ophthalmology.

Vice-President.—Richard Andrew Reeve, B.A., M.D., LL.D., Professor of Ophthalmology and Otology, University of Toronto.

Council.—J. W. Stirling, M.D., Professor of Ophthalmology, McGill University.

Section X.—Diseases of Children.

Council.—Allen MacKenzie Baines, M.D., Associate Professor of Pædiatrics, University of Toronto.

Section XI.—Neuropathology.

Council.—D. A. Shirres, M.D., Lecturer in Clinical Neurology, McGill University; Ernest Jones, M.D., B.S., M.R.C.P., Associate Professor of Psychiatry, University of Toronto.

Section XII.—Psychiatry.

Vice-President.—C. K. Clarke, M.D., Professor of Psychiatry, University of Toronto.

Council.—T. J. W. Burgess, M.D., F.R.C.S., Professor of Mental Diseases, McGill University; W. H. Hattie, M.D., Medical Superintendent, Nova Scotia Hospital; Edward Ryan, M.D., Professor of Mental Diseases, Queen's University, Kingston.

Section XIII.—Dermatology.

Council.—Philip Burnett, M.D., Montreal General Hospital; G. G. Campbell, B.Sc., M.D., Lecturer in Medicine and Clinical Medicine and in Dermatology, McGill University; David King Smith, M.B., Toronto General Hospital.

Section XIV.—Urology.

Council.—Edmund E. King, M.D., Toronto.

Section XV.—Rhinology.

Vice-President.—J. D. Gibb Wishart, B.A., M.D., C.M., Associate Professor of Laryngology and Rhinology, University of Toronto.

Section XVI.—Otology.

Vice-President.—H. S. Birkett, M.D., Professor of Otology, McGill University.

Section XVIII.—Hygiene.

Vice-President.—Charles A. Hodgetts, M.D., C.M., Medical Adviser, Commission of Conservation, Ottawa.

Council.—R. M. Simpson, M.D., M.O.H. for the Province of Manitoba.

Section XIX.—Forensic Medicine.

Council.—D. B. MacTaggart, M.D., Professor of Medical Jurisprudence, McGill University.

Section XX.—Naval and Military Medicine.

Vice-President.—Colonel Guy Carleton Jones, M.D., C.M., M.R.C.S., Director-General, Medical Services, Militia of Canada, Ottawa.

Council.—Lieutenant-Colonel J. T. Fotheringham, M.D., Army Medical Corps, Toronto.

Section XXI.—Tropical Medicine.

Council.—J. L. Todd, B.A., M.D., B.Sc., Associate Professor of Parasitology, McGill University.

Section XXII.—Radiology.

Council.—F. C. Harrison, B.A., M.B., Assistant in Pharmacology, University of Toronto, Physician, Toronto Hospital for Incurables.

A GLIMPSE AT OLD-TIME CAMBRIDGESHIRE DOCTORS.

THE kind of history that consists merely of recounting a number of isolated facts is of little profit. It is safe to say that reconstructive works, such as Becker's "*Gallus*" and his "*Charicles*," convey a better concrete idea of the actual daily life in classical times than any amount of the kind of classical reading which we do as schoolboys. We must learn to view archæological remains with the mind's eye as part of the reconstructed whole. We are led to these reflections by the perusal of a pamphlet by Dr. W. M. Palmer on "Cambridgeshire Doctors in the Olden Time,"[1] wherein we are shown these worthies, not as curiosities in a museum, but as human beings, living their lives as professional men in an environment superficially so totally unlike, and yet in its fundamentals so essentially the same as our own.

Some Interesting Details.

Dr. Palmer's paper deals chiefly with the sixteenth and seventeenth centuries. He brings the dry bones to life by giving us, after a preliminary excursus on his sources of information, the regulations of early medical practice, and the various grades of medical practitioners, an interesting and humorous sketch of two village practitioners, respectively of the sixteenth and seventeenth centuries, as well as equally interesting records of certain Cambridge doctors—viz., Walter Lemster, physician (? 1440)–1487; John Thomas, surgeon (? 1490)–1545; Robert Pickering, physician (a contemporary of Thomas); John Hatcher, M.D. (? 1512)–1587; Thomas Lockyn, M.D., 1528–1591; and William Butler, 1536–1618.

The first important Medical Act, passed in 1511, required, as regarded country doctors, that no person should practise as a physician or surgeon in any diocese until he had been examined and approved by the Bishop, aided by such expert persons in those faculties as were convenient. The penalty was £5, or £50 of our money, for each month in which he practised without such licence. A search through the Bishop's Court books discovered 15 medical practitioners in the diocese of Ely in 1640, of whom four were in Cambridge and the rest at Brinckley, Chatteris, Chesterton, Coton, Cottenham, Ely, Ickleton, Melbourn, Meldreth, Shudy Camps, and Wisbech, though this list is probably not complete. There were also 33 midwives in the county and Isle of Ely. The six recognised grades of practitioners appear to have been physicians, surgeons, barber-surgeons, apothecaries, midwives, and bone-setters, of whom the first four had either to take a degree or licence at one of the universities or to pass through an apprenticeship.

Dr. Palmer appears to doubt the truth of the general opinion as to the low status of the surgeon of those days, for he says: "Most of the writers on the history of medicine have been physicians, and they have invariably put the position of the surgeon as a low one."

A Country Practitioner at the End of the Sixteenth Century.

Speaking of the real country practitioner, the doctor living in a country village, with no colleague within several miles, Dr. Palmer tells all he has been able to find out about one Mr. John Stacey, a predecessor of his own in Linton, who first came under his notice through the records of a medico-legal case of 1581. A woman having been indicted before the Bishop's Court "for incontinency and contingent offences," called in her defence her doctor, Robert Widdows, of Cambridge, but "either Dr. Widdows had scruples about divulging professional secrets, even in the spiritual court, or did not want to be cross-examined, or Mrs. Horner hadn't paid her bill—anyway he wouldn't give evidence." So she fell back on her husband's doctor, Mr. John Stacey, of Linton, who attended and gave evidence in support of her character. What the issue of the trial was we are not told, but we learn of Stacey that he was at one time a trusted member of Sir Phillip Paris's household, who left him the keeping of his house in Linton during the nonage of his son Robert. On Robert's death before attaining his majority, Stacey bought a house in Linton and settled in practice. He seems to have been successful, for in 1592 he paid the fifth highest amount of taxes in Linton.

Another Country Doctor (1685).

The house of another country doctor, Mr. John Longworthy, a practitioner in physic and surgery, West Wrattling, a small country village, in 1685, is described as follows:—

> The house consisted of hall, great and little parlours, closet for drugs and surgical instruments, kitchen, pantry, and cellar, with five bedrooms and a garret which was used as a granary. A building with two gables and a connecting hall, such as still exist in this county, would fit this description. On entering the hall you would have seen two gate-legged tables, five joined stools, a grandfather's clock, and a corner cupboard. The hearth contained a fire grate, but the floor was carpetless. In the little parlour was an oval table and six painted chairs. No carpet and an open hearth. In the great parlour was the only carpet in the house; an oval table, probably of walnut, six leather and two panelled chairs and an open hearth with large cobirons. As regards the bedrooms, the hall chamber and the great parlour chamber contained fireplaces, which were also open hearths. In the former was a four-poster bed, a carved oak hutch, three chairs, and a pair of bellows. In the great parlour bedroom, evidently the best bedroom, was another four-poster with curtains, a chest of drawers, and a looking-glass, altogether valued at £10, the most expensively furnished room in the house. The other bedrooms were meanly furnished and without fireplaces. One of them is called the manservant's room, so the doctor's groom slept in the house. In the kitchen was a table, with four chairs and a screen. The value, including roasting apparatus, brass and pewter, was £6 10*s*. The only eating utensils mentioned besides this pewter are a case of knives in the pantry and some earthenware.

Of linen there was goodly store, 12 pairs of sheets and five dozen table napkins (forks were not then in general use in England so that the fingers required constant wiping); and this, Dr. Palmer reminds us, was linen that did not wear out and was often bequeathed in wills. In the cellar were four half-hogsheads of beer and smaller barrels, and there was a cider press in the brewhouse. "His instruments and utensils for physic and chirurgery, two stills, one mortar, and a few old books, £4," were of exactly the same value as his linen. Dr. Palmer depicts his subject as probably spending many hours "grinding dried roots to powder in his mortar, with one eye and ear on the bubbling of the fluid in his still," and shrewdly remarks: "A man who spent hours in the preparation of his physic had more faith in it than some have nowadays." Mr. Longworthy was also a farmer, as many country doctors are to some extent to-day, and his agricultural goods amounted to £65 out of a total of £121.

Much quaint information has been collected by Dr. Palmer

[1] Cambridgeshire Doctors in the Olden Times, 1466–1827. By W. M. Palmer, M.D. Durh. From the Cambridge Antiquarian Society's Communications, vol. xv., 1911.

about the drugs used by a country doctor of the eighteenth century. Occasionally possessions to be found in the inventories suggest the spoil of churches. For instance, Dr. Hatcher, of Cambridge (? 1512–1587), possessed, among other things, "a cope of tissue upon green velvet, with a cape and border of images of needlework," valued at 35*s.*, and "an auter cloth of purple velvet with branches 3¾ yards, 25*s.*"

The Case of a Cambridgeshire Vicar.

Dr. Palmer concludes his very interesting paper with "a sad account of a Cambridgeshire vicar of the fifteenth century who was dissatisfied with local skill and went to London for further advice," which he sought from John Brown, warden of the Barber-Surgeons in 1494. The latter undertook to "do his cure" on the parson, who on his part undertook to pay £10 (half a year's stipend of his vicarage), half when he could walk without a crutch and hold up his arms so that he might say mass, the other half 13 weeks after he was completely whole. But he committed the mistake, poor simple soul, of signing an obligation of £20 to compel him to fulfil his bargain when cured. After he had been more than six months in the city at great expense to himself, the surgeon asked for his fee and was met with the objection, "But I am in like case as I was when first you took me in cure and no better." He refused to pay and the surgeon ceased to attend.

The poor vicar's expostulation, however, was fruitless, for the surgeon commenced an action for debt by means of the obligation against the vicar in the Sheriff's Court, to which the vicar put in surety and was prepared to answer. But the wily surgeon knew a trick worth two of letting the case come to trial, for, in Vicar Dobson's own words, "Brown now proceedeth no further in the action, but lets it depend in the court, to thentente that Dobson should lie styll in London to his grete costs and charges unto such tyme as by that means he shulde be fain to pay Brown £5, that he demandeth for his labour." No more is known about the case, but as the next appointment to the vicarage of Melbourn occurred in 1503, the vicar probably lived until then. Dr. Palmer closes his paper with the pithy remark, "The fame of London specialists must have been dim in that village for many years to come."

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

Proposed Extension of the Present System of Medical Treatment.

THE Children's Care Committee reported to the Education Committee of the London County Council on March 6th that it had approved certain variations in the number of cases dealt with at the treatment centres controlled by committees of medical practitioners in Islington, St. Pancras, and Hackney. An offer had been considered from a voluntary committee, not wholly composed of medical practitioners, to establish an additional centre in Poplar for treatment on five afternoons a week upon the conditions proposed in respect of other centres. The committee had approved of arrangements with this local committee for twelve months, the number of children to be dealt with being 880 suffering from eye defects and 1320 suffering from ear, nose, and throat ailments. The Metropolitan Hospital, Kingsland-road, was prepared to undertake the treatment of 500 eye cases and 500 ear, nose, and throat cases a year upon the terms usually offered by the Council, and the Care Committee had agreed to the inclusion of this hospital in the medical treatment scheme as likely to be of assistance in meeting the needs of Haggerston and South Islington. The Committee had also accepted an offer by the authorities of St. Cecilia's Home, Commercial-road, Stepney, to arrange for the cleansing of verminous children and for the medical treatment of ailing children. Treatment would be provided for 440 cases and it would be given in two inter-communicating rooms. A doctor would attend on one half day a week; his salary would be paid by the Council. The cost if 440 cases were treated for ear, nose, and throat ailments not requiring operations and for external eye diseases would be £104 a year.

In connexion with the foregoing the Care Committee drew attention to the steps taken by the Council since the autumn of 1911 (in accordance with the promise to the Board of Education), with a view to coördinating medical inspection and treatment, and to securing the efficiency of the treatment centres. Under newly proposed arrangements the following provisions were included: (1) The local committees had agreed that the doctors themselves who performed the work (instead of as heretofore their qualifications only) should be subject to the approval of the Council; (2) arrangements for the attendance of a lay officer or a nurse to supply information to school care committees as to the nature of treatment ordered by the doctors were now in operation at all the existing centres, and it was proposed to extend them to suggested centres; (3) the school doctors and the doctors at the centres would exchange information; and (4) the adoption of the proposals now made would give the Council experience of providing treatment at three types of centre—namely, at hospitals, at centres established by local practitioners, and at centres provided by committees which were not composed of medical practitioners. The committee felt that the Board of Education should be informed of these points, and also of the experiment approved at the end of 1911 and put into force on March 1st this year, in the East-end of London, in carrying out medical inspection by full-time officers under the supervision of a divisional medical officer, who would work in close coöperation with the Council's officers at the treatment centres. The Board should be asked to sanction the establishment of the proposed additional centres as a matter of urgency, inasmuch as there was special need for the treatment of children in the districts which would be served by the centres. A comprehensive report on the work of medical treatment in London generally would be submitted in October next. The total expenditure involved in the present proposals was £3565 a year for treatment and £475 in the first year for apparatus.

The Education Committee directed that a letter in these terms be sent to the Board of Education.

Playground Classes.

The Board of Education, while commenting favourably on the improved arrangements for medical supervision recently introduced into playground classes, has made certain suggestions to the London County Council with a view to bringing about further improvements. These were submitted to the Council on Feb. 20th. In classes in which all the children are definitely chosen on the ground of delicacy of health the Board thought it was desirable that every child should be subjected to systematic medical inspection as early in the session as practicable, and that all initial and subsequent records made by medical officers should be dated. In classes in which the influences needed were mainly preventive the Board thought that the medical examination should be conducted on more uniform lines than at present. While some examinations were thorough, others appeared to omit such important details as the chest and lungs, others again included merely such items as could be gathered from simply looking at the child, while in some of the schools medical supervision of every kind was omitted. That there was need for inspection of the more thorough kind was obvious from the serious cases of defect that occurred in certain of the classes, the scholars of which had been subjected to medical inspection. It was important that the results of routine medical inspection should be re-entered on playground class records (as was done in some cases) in order that the open-air class might be better utilised as a means of following up those cases most likely to benefit under its influence. "Control" measurements might be more generally instituted in classes of the kind referred to, and they should have special reference to height, weight, and hæmoglobin content. The Board pointed out that the open-air class was an experiment likely to yield results useful to the whole country, and it was important, therefore, that its usefulness should rest on scientific bases of the kind to be obtained by means of "control" measurements.

The Council decided to ask the medical officer to meet the suggestions of the Board as far as possible.

The Council also resolved to ask the Board of Education to approve the formal appointment of Dr. W. H. Hamer for the purpose of certifying defective or epileptic children within the meaning of Section 1 of the Elementary Education (Defective and Epileptic Children) Act, 1899.

Medical Inspection of Secondary Scholars.

The Education Committee reported that the governors of Lewisham Grammar School had asked whether it would be possible for the Council's medical officer, in examining the scholarship holders at the school, also to examine other pupils at a fixed fee per pupil to be paid by the pupil's parents. The committee pointed out that the Council had already decided to examine all pupils, whether fee-paying or scholarship holders, in its own secondary schools, and so had accepted the principle that medical examination of all pupils was desirable. The cost of the examination of the fee-paying pupils would not exceed 2*s.* a year per pupil, and the committee recommended that the governors' request should be granted on this basis.

Principle of Open-air Schools Approved.

The Education Committee of the London County Council has had under consideration the policy to be pursued with regard to open-air schools, and has decided that, having now passed the experimental stage, they should be placed on a permanent basis. The first open-air school was held at Bostall Woods in 1907, and in view of the great improvement in the health of the children who attended it was decided to extend the experiment to three schools for 1908. In 1911 the schools were continued a greater number of weeks than in previous years—in one case the school was held during the whole year. The favourable medical reports upon the open-air schools held during the year 1908 had been confirmed in successive years. It was evident, the Special Schools Committee stated, that children suffering from debility, anæmia, &c., and consequently unable to benefit from the instruction in ordinary schools, could be restored to take their places in their classes. The physical and intellectual improvement shown was very remarkable, and the committee had come to the conclusion that these results were due in a large measure to the course of instruction given under open-air conditions. In regard to the extension of open-air schools, playground classes would have a material effect in reducing the number of children who required the *régime* of the open-air school. The medical officer, however, stated that there was a large number of children in London elementary schools suffering from some specific condition requiring such treatment, and presumably there would always remain an appreciable number of these.

At the same time the committee pointed out there were two great difficulties in the way of any considerable extension of the system of open-air schools: one was the extreme difficulty of obtaining sites, and the second the cost, which was very high as compared with that of ordinary schools. The average cost per head of attendance for nine months at open-air schools was £14 7*s.*, and at ordinary schools £1 9*s.* Having regard to these circumstances, while the principle of holding a limited number of open-air schools should be approved, any extension of the system should be very gradual. When the playground classes were in fuller operation, and more use was made of existing opportunities of open-air work, it would be possible to gauge the amount of special provision still necessary.

LITERARY INTELLIGENCE.—We have received from Messrs. John Wright and Sons, Limited, of Bristol, an unbound and incomplete copy of "An Index of Differential Diagnosis of Main Symptoms," by Dr. Herbert French, with the explanation that now that their own work is practically over—as evidenced by the book before us—there seems likely to be a still further delay in binding owing to the coal strike. This is, of course, the more regrettable as the publishers admit that already they have had to keep their subscribers waiting an unconscionable time after the probable date of publication owing to the difficulty in construction of the general index, which turned out a formidable task greatly exceeding their expectations.—Messrs. J. and A. Churchill announce the following for immediate publication: "Diseases of the Eye, a Manual for Students and Practitioners," by Mr. J. H. Parsons. A new feature in this, the second, edition will be the inclusion of a colour test card in wools. The same firm is publishing a seventh edition of "A Simple Method of Water Analysis," by Dr. J. C. Thresh; and a second edition of "The National Standard Dispensatory," edited by H. A. Hare, B.Sc., M.D., Charles Caspari, and H. R. Rusby, M.D.

MEDICINE AND THE LAW.

The Constituents of Butter.

AT the Tower Bridge police court recently a summons against the Central Creamery Company, Limited, which had been dismissed upon a technical point and sent back for re-hearing after an appeal, was heard by Mr. Rose and dismissed, with £40 costs, against the Board of Agriculture, which was responsible for the prosecution. The prosecution sought to show that the presence of certain milk powder found upon the premises of the defendant company constituted an offence against Section 3 of the Butter and Margarine Act, 1907, and it was also alleged that the high percentage of lactose contained in butter found upon the defendants' premises showed that milk powder had been used in its preparation. It had been stated that the powder was the property of a director of the company and was stored upon its premises pending its sale to private customers. Mr. Otto Hehner, giving evidence for the defence, said that the blending, reworking, and renovating of butter was necessary for the production of an article of uniform quality such as was required in such a business as the defendants'; that milk powder was largely used in connexion with such renovation; and that any person using modern methods would so employ sterile milk powder. He also deposed that whereas butter usually contained 0·4 per cent. of lactose, he had found in samples as much as 1·2 per cent., whereas 1·5 was the amount shown by the sample taken on the defendants' premises. He assured the magistrate that it would have no harmful effect, and stated that he always accepted as butter an article containing 80 per cent. of butter-fat. Further evidence given by analysts showed that all the constituents of milk powder were found in all butter, and that it had a high nutritive value. It was agreed as to the standard of 80 per cent. of butter-fat being sufficient, and as to the good quality of the defendants' butter. Mr. Rose found that the milk powder was not intended to be used for the adulteration of butter, and dismissed the summons as stated above.

Excessive Use of Thyroid Extract.

At the Westminster Bridge police court recently Mr. Horace Smith had before him, upon a charge of stealing from the Army and Navy Stores, the wife of a colonel in the army, who had taken a number of articles exposed for sale, and while purchasing in the drug department a large quantity of thyroid extract had also abstracted two boxes of throat pastilles. Evidence was given by Mr. T. L. Archer, divisional surgeon of police, which left no doubt that when he was called to attend the prisoner at the police station she was in a highly nervous and excited condition, and that this was due to her having been deprived, while in custody, of the thyroid extract which she had bought and of which drug she had been in the habit of consuming large quantities. Mr. Archer was of the opinion that her mental condition, due to the abuse of the drug, would fully account for her committal of the acts with which she was charged. Dr. J. D. Cree, who had treated the prisoner for some months, deposed that she was suffering from Graves's disease, for which he had prescribed thyroid extract. He had increased the dose from 3 to 11 grains a day between September and Jan. 3rd, when he last saw her, and he was not aware then that she was exceeding the latter amount. By her own admission, however, she had taken recently as much as 35 or 40 grains daily, an excessive amount which would account for her condition and acts. He considered that the effect would be to destroy her mental balance, and that on Jan. 9th when she was arrested, she was not accountable for her actions. Mr. Horace Smith accepted the view expressed by the two medical witnesses, and said that it was unnecessary to hear further evidence to the same effect, which was tendered. In the course of his evidence Mr. Archer had called attention to the ease with which such a drug as thyroid extract might be purchased, Mr. P. Conway, the lady's solicitor, also making observations upon the subject. The magistrate declined to comment upon this aspect of the matter, remarking that it was not part of his duty to do so, as he was not a legislator, but the case will be noted as illustrating the danger which arises, even assuming a prescription to be in

the hands of a purchaser, owing to the existence of no legal limitation as to the frequency or continuance of its use.

General Practitioners and their Locum-tenents.

A case of considerable interest to general practitioners, arising out of the engagement of a locum-tenent, was heard at the Clerkenwell county court on March 5th. The action was brought by Mr. Henry Bazett against Dr. Thomas G. Hockridge of Lloyd-square, W.C., for £26 8*s.* in respect of damages arising out of an alleged breach of contract. The material question at issue was that of the length of notice which a locum-tenent was entitled to receive in termination of his engagement. The plaintiff stated that the defendant had made a contract with him to act as locum-tenent from Nov. 30th, 1911, to Jan. 16th, 1912, at the rate of 4 guineas per week, and board and lodging. On Dec. 15th, the plaintiff, through illness, had to leave the defendant's house for temporary rest and on his recovery he was refused permission to continue his duties. The claim was for £19 4*s.*, salary for four weeks and four days, and £7 4*s.* as an equivalent to board and lodging for the same period. The defendant called evidence of a custom in the profession of 48 hours' notice to terminate such an engagement. The plaintiff denied this, and contended that each medical man had his own rules, and that these varied. In the case of illness of a doctor a locum-tenent was engaged for an indefinite period; if the engagement was by the day payment was at the rate of 1 guinea per day. The defence was that a principal could dismiss a locum-tenent at practically a moment's notice. It was only a temporary engagement, though payment was usually made weekly for the sake of convenience. The defendant cited 38 years' experience of such engagements which were always subject to 48 hours' notice. The plaintiff, in addressing the bench, submitted that the relation between principal and locum-tenent was that of master and servant, and that it would be an exceedingly hard and serious thing for the locum-tenent to be placed outside that law and, because of illness, have to bear the brunt of it all. In giving judgment his honour said that the plaintiff fell ill and had to be replaced by another locum-tenent. The plaintiff took up the position that "although you have to pay somebody else you must pay me as well." It seemed to him impossible to accept that conclusion. The principal of the law of master and servant did not apply in this instance and judgment must be for defendant with costs. The plaintiff asked whether he had the right to appeal, to which his honour replied in the affirmative.

An Interesting Case under the Workmen's Compensation Act.

Recently at the Weston-super-Mare county court, before his Honour Judge Austen, the widow of a chef at a local hotel claimed £300 under the Workmen's Compensation Act for the death of her husband. The deceased man, whilst dressing in his room in the hotel, slipped over a mat, and complaining of great pain went home and sent for a medical man. The medical attendant stated that deceased had abdominal pains, and a post-mortem examination showed that death was caused by hæmorrhage from a ruptured right renal artery. He added that although he had never known or read of a renal artery being ruptured by a violent twist, he considered in this case that that had occurred and caused death. The medical man was not allowed to state what the deceased had told him of the accident—viz., that he had slipped whilst dressing and violently twisted himself—his Honour holding that the statement would not be evidence. Judge Austen, in deciding against the claim, said he was not satisfied that an accident had taken place, or that it arose out of, and in the course, of the deceased man's employment.

Libel Action brought by a Dentist.

A most righteous verdict was given on Tuesday last by a King's Bench jury, when Mr. F. R. Moser was awarded £600 damages for libel, the defendants, Mr. George Smith, a Camberwell builder, and his wife having accused him of improper behaviour towards the female defendant while she was his patient. The accusations were obviously and utterly untruthful.

THE Princess Henry of Battenberg has consented to become a vice-patron of the Chelsea Hospital for Women.

Public Health.

REPORTS OF INSPECTORS IN THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On an Outbreak of Enteric Fever at Oakenshaw, in the Urban District of Willington, by Dr. T. CARNWATH.—Oakenshaw is a mining village with a population of some 1280 persons, about seven miles to the south-west of the city of Durham. It is included in the urban district of Willington, in which enteric fever has been endemic for many years. Before 1909 Oakenshaw itself was relatively free from the disease, but in that year sporadic cases began to occur in the village with unusual frequency, and this continued on into 1910, finally culminating in a severe outbreak in April and May, which was practically confined to the village, and did not extend to other parts of the Willington district. Systematic application of the Widal test at the time of Dr. Carnwath's inquiry suggested that many cases of illness had occurred which were to be attributed to enteric fever infection, although for one reason or another they had not been notified. Dr. Carnwath concludes that there were altogether 74 cases, 11 of which occurred in 1909 and the remainder in 1910; of these 74 cases 7 were fatal. As many as 33 occurred in the last week of April and in the first week in May, and special attention was directed to the explanation of this striking feature of the outbreak. The latter appeared almost certainly to be due to a milk infection. The milk-supply of the village was obtained mainly from three farms, of which one farm, X, supplied 85 households, or 35·1 per cent. of the total houses in Oakenshaw. Of the 57 invaded households as many as 49 obtained milk from farm X, and there was evidence that the attack of the few persons who were customers of the other farms might be attributed to those farms having had dealings in milk with the X farm. The amount of milk delivered daily to each household was on an average from half a pint to a pint; it was generally found that the member of the family who fell ill was the one who "drank most milk," but even so the quantity consumed in the majority of cases was exceedingly small. A heavy proportional incidence of the disease on females and children gave confirmatory evidence of the infection having been milk-borne. At the farm X only two persons, mother and son, had anything to do with the handling of the milk from the time it left the udder until it was delivered to the customer, and this had been so for 12 years. No history of enteric fever could be obtained in either case, although the son had suffered from a "bad cold" with some affection of the lungs and bowels in 1908. The mother had no history of any sickness save a liability to bilious attacks. Samples of urine and fæces obtained from the son were examined by Dr. J. C. G. Ledingham at the Lister Institute for typhoid bacilli with negative results, but those obtained from the mother in August, 1910, and again in December, contained large numbers of typhoid bacilli. It may reasonably be concluded, therefore, that Mrs. X somehow caused the infection of the milk at intervals during 1909 and 1910, and did so with particular intensity in April of the latter year. The question why this infective ability was not shown, at any rate to any conspicuous extent, before 1909 did not admit of any satisfactory answer.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 8603 births and 4846 deaths were registered during the week ending March 9th. The annual rate of mortality in these towns, which had steadily decreased from 21·6 to 15·4 per 1000 in the four preceding weeks, further declined to 14·4 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these large towns averaged 16·7 per 1000, while in London during the same period the average death-rate did not exceed 15·9 per 1000. The annual death-rates last week in the several towns ranged from 6·0 in Hornsey, 6·3 in Enfield, 6·8 in Gillingham, 7·3 in Walthamstow, and

7·5 in Ilford, to 20·3 in Great Yarmouth, 20·7 in Oldham, 21·0 in Stockton-on-Tees, 24·2 in Salford, and 25·8 in Barrow-in-Furness.

The 4846 deaths from all causes were 348 fewer than the number in the previous week, and included 378 which were referred to the principal epidemic diseases, against 353 and 394 in the two preceding weeks. These 378 deaths from the principal epidemic diseases included 136 from whooping-cough, 101 from measles, 53 from infantile diarrhœal diseases, 49 from diphtheria, 25 from scarlet fever, and 14 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·1 per 1000, against 1·0 and 1·2 in the two preceding weeks. The deaths attributed to whooping-cough, which had decreased from 186 to 142 in the four preceding weeks, further declined to 136 last week, and caused the highest annual death-rates of 1·7 in Southampton and in Walsall, 1·8 in Great Yarmouth, 2·4 in Barrow-in-Furness, and 2·5 in Merthyr Tydfil. The deaths referred to measles, which had increased from 69 to 109 in the three previous weeks, slightly declined to 101 last week; the highest annual death-rates from this disease were 1·3 in Swansea, 1·4 in Oldham, 1·9 in York, 2·0 in Southport, 3·6 in Warrington, and 4·3 in Salford. The fatal cases of infantile diarrhœa, which had been 58, 39, and 49 in the three preceding weeks, were 53 last week, and included 17 in London, 7 in Liverpool, 4 in Stoke-on-Trent, 4 in Sheffield, and 3 in Birmingham. The deaths attributed to diphtheria, which had increased from 43 to 53 in the three previous weeks, were 49 last week; 14 deaths were recorded in London and its suburban districts, 4 in Portsmouth, 4 in Manchester, and 3 in Leeds. The deaths referred to scarlet fever, which had been 28, 17, and 21 in the three preceding weeks, rose to 25 last week, and included 5 in London, 4 in Manchester, and 3 in Leeds. Of the 14 fatal cases of enteric fever, which were 5 less than the average in the three preceding weeks, 3 were registered in London, 2 in Manchester, and 2 in Rotherham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had decreased from 1512 to 1392 during the four preceding weeks, had further declined to 1358 on Saturday last; 161 new cases of this disease were admitted to these hospitals during the week, against 154, 181, and 160 in the three previous weeks. These hospitals also contained on Saturday last 1113 cases of diphtheria, 478 of whooping-cough, 231 of measles, and 58 of enteric fever, but not one of small-pox. The 1152 deaths from all causes recorded in London were 76 fewer than the number in the previous week, and were equal to an annual death-rate of 13·3 per 1000. The deaths referred to diseases of the respiratory system, which had steadily declined from 545 to 295 during the four preceding weeks, further fell to 259 last week, and were 69 below the number registered in the corresponding week of last year.

Of the 4846 deaths from all causes in the 94 large towns, 169 resulted from different forms of violence, and 358 were the subject of coroners' inquests. The causes of 39, or 0·8 per cent., of the deaths registered last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, Nottingham, Portsmouth, and in 66 other smaller towns. The 39 uncertified causes of death last week included 9 in Liverpool, 8 in Birmingham, 3 in Preston, 2 in Salford, and 2 in South Shields.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns, having an estimated population of 2,182,400 persons in the middle of this year, 1138 births and 731 deaths were registered during the week ending March 9th. The annual rate of mortality in these towns, which had been 18·5 and 18·7 per 1000 in the two preceding weeks, declined to 17·5 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual rate of mortality in these towns averaged 18·9 per 1000, and was 2·2 per 1000 in excess of the mean rate recorded during the same period in the 94 large English towns. The annual death-rates in the several Scotch towns last week ranged from 4·6 in Partick, 7·6 in Falkirk, and 9·0 in Clydebank, to 22·0 in Greenock, 22·5 in Kilmarnock, and 23·1 in Perth.

The 731 deaths from all causes were 53 fewer than the number in the previous week, and included 76 which were referred to the principal epidemic diseases, against 120 and 93 in the two preceding weeks. Of these 76 deaths, 39 resulted from measles, 10 from scarlet fever, 8 from whooping-cough, 8 from diphtheria, 8 from infantile diarrhœa, and 3 from enteric fever, but not one from small-pox. These 76 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000, or 0·7 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had decreased from 63 to 56 in the three preceding weeks, further declined to 39 last week, and included 21 in Glasgow, 6 in Edinburgh, 4 in Greenock, and 3 in Leith. The deaths referred to scarlet fever, which had been 2, 3, and 6 in the three preceding weeks, further rose to 10 last week, and comprised 5 in Glasgow, 3 in Greenock, and 2 in Aberdeen. The fatal cases of whooping-cough, which had been 14 18, and 16 in the three preceding weeks, fell to 8 last week, and included 3 in Glasgow and 2 in Edinburgh. The deaths referred to diphtheria, which had been 6, 22 and 9 in the three previous weeks, were 8 last week, of which number 5 occurred in Glasgow. The deaths of infants under two years of age from diarrhœal diseases numbered 8, against numbers declining from 14 to 5 in the three preceding weeks; 2 deaths were recorded in Glasgow, in Dundee, and in Paisley. The 3 fatal cases of enteric fever were registered in Glasgow.

The deaths referred to diseases of the respiratory system in the 18 towns, which had decreased from 220 to 138 in the four preceding weeks, further declined to 136 in the week under notice, and 29 deaths were attributed to different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having a population of 1,157,014 persons in the middle of this year, 622 births and 512 deaths were registered during the week ending March 9th. The annual rate of mortality in these towns, which had steadily declined from 31·0 to 22·1 per 1000 in the four preceding weeks, rose to 23·1 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these Irish towns averaged 23·5 per 1000; in the 94 large English towns the mean annual death-rate during the same period did not exceed 16·7 per 1000, while in the 18 Scotch towns it was equal to 18·9 per 1000. The annual death-rates in the several Irish towns last week were equal to 26·9 in Dublin (against 13·3 in London), 20·3 in Belfast, 24·5 in Cork, 30·6 in Londonderry, 19·0 in Limerick, and 7·6 in Waterford; while in the 16 smallest of these Irish towns the mean annual death-rate last week was equal to 21·3 per 1000.

The 512 deaths from all causes in the 22 Irish towns were 22 in excess of the number in the previous week, and included 41 which were referred to the principal epidemic diseases, against 27 and 36 in the two preceding weeks; of these 41 deaths, 13 resulted from whooping-cough, 13 from infantile diarrhœal diseases, 5 from enteric fever, 5 from diphtheria, 4 from measles, and 1 from scarlet fever, but not one from small-pox. These 41 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000; the death-rate last week from these diseases did not exceed 1·1 per 1000 in the 94 large English towns, while in the 18 Scotch towns it was equal to 1·8. The deaths attributed to whooping cough, which had declined from 25 to 16 in the four preceding weeks, further fell to 13 last week, and included 11 in Belfast. The deaths of infants under two years of age from diarrhœal diseases, which had been 5 and 9 in the two previous weeks, further rose to 13 last week; 6 deaths were registered in Dublin and 4 in Belfast. The 5 fatal cases of enteric fever were in excess of recent weekly numbers, and comprised 2 in Dublin, 2 in Belfast, and 1 in Limerick. The 5 deaths referred to diphtheria were 3 in excess of the average in the three preceding weeks, and included 3 deaths in Dublin. The 4 deaths from measles were recorded in Dublin, and that from scarlet fever in Belfast.

The deaths referred to diseases of the respiratory system, which had steadily declined from 239 to 135 in the four preceding weeks, were again 135 last week. Of the 512

deaths from all causes in the 22 Irish towns, 149, or 29 per cent., occurred in public institutions, and 11 resulted from different forms of violence. The causes of 32, or 6·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 large English towns the proportion of uncertified causes of death in the week under notice did not exceed 0·8 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff Surgeons: A. McCloy to the *Research*, and J. R. A. Clark-Hall to the *Triton*. Surgeons: E. Moxon-Browne to the *Hearty;* D. A. Mitchell to the *Dido* and to the *Alert*, on recommissioning; and J. H. Wright to the *Terrible*, temporary.

ROYAL ARMY MEDICAL CORPS.

Lieutenant Edward S. Calthrop resigns his commission (dated March 9th, 1912).

Surgeon-General G. D. Bourke, C.B., K.H.P., has been appointed on the directing staff of the Irish Command Staff tour to be held from March 25th to the 28th.

Colonel L. E. Anderson has been granted 2½ months combined leave of absence. Colonel H. J. Barratt has taken up duty as Principal Medical Officer of the Allahabad Brigade.

Lieutenant-Colonel S. C. Philson has been selected for the increased rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel C. H. Melville has been selected for promotion to the rank of Brevet-Colonel. Lieutenant-Colonel A. L. F. Bate, on return from India, has been posted to the Western Command. Lieutenant-Colonel J. V. Savage has been transferred from Muttra to the station hospital at Secunderabad.

Major J. Cowan, from Woolwich, has embarked for a tour of service in India. Major F. G. Richards has taken up duty in the Cork District. Major P. MacKessack has joined ths Eastern Command headquarters as Specialist Sanitary Officer, vice Major C. H. Stratton, who has embarked for service abroad. Major R. S. H. Fuhr, D.S.O., and Major W. E. Hardy have been permitted by the Director-General to exchange places on the foreign service roster. Major L. Wood has been appointed to the Fourth (Quetta) Division. Major C. W. Reilly has been ordered to join the Irish Command on March 21st and will be posted to the Cork District. Major C. Dalton and Major D. J. Collins have been detailed for duty in connexion with the Irish Command Staff Tour. Major G. S. McLoughlin, D.S.O., has taken up duty at Winchester. Major M. Swabey has been transferred from Wellington to St. Thomas's Mount, Madras.

Captain C. G. Browne has been granted six months' general leave of absence home from India. Captain T. S. Blackwell has been directed to join for duty in the Irish Command on March 21st and will be posted to the Belfast District. Captain G. Baillie has embarked for a tour of service on the West Coast of Africa. Captain M. Keane has been appointed to the Eastern Command. Captain W. R. Galwey has been appointed Specialist Sanitary Officer to the Ninth (Secunderabad) Division, in succession to Major R. W. Clements. The following transfers have been made in India: Captain J. B. Hanafin from the Second (Rawal Pindi) Division to the First (Peshawar) Division; Captain C. D. Caddell from the Fifth (Mhow) Division to Aden; Captain T. S. Eves from the Seventh (Meerut) Division to the Eighth (Lucknow) Division; and Captain D. Coutts from the Eighth (Lucknow) Division to the Seventh (Meerut) Division. Captain A. Dawson has been selected for appointment to hold charge of the Brigade Research Laboratory at Aden. Captain A. H. Bond has been granted six months' general leave of absence home from India. Captain L. L. G. Thorpe has been transferred from the Royal Victoria Hospital, Netley, to Golden Hill. Captain V. T. Carruthers has been posted to the Cork District. Captain C. P. O'Brien Butler has been transferred from Poona to Purandhar. Captain C. T. Edmunds has joined the station hospital, Peshawar, for duty. Captain W. E. C. Lunn has been granted six months' general leave of absence home from India from March 12th. Captain G. A. K. H. Reed has been appointed Company Officer at the Royal Army Medical Corps Depôt, Aldershot. Captain P. C. Douglass, from Weedon, and Captain H. A. Bransbury, from Woolwich, have embarked for a tour of service in India. Captain M. W. Falkener has joined for duty in Bermuda. Captain F. C. Sampson has been transferred to the home establishment from South Africa. Captain W. J. E. Bell has arrived home on duty from Hong-Kong.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel J. Chaytor White has been granted an extension of three months' leave on medical certificate. Lieutenant-Colonel A. W. Dawson has been appointed to hold Civil Medical Charge at Roorkee. The services of Lieutenant-Colonel A. O. Evans, civil surgeon of Maymyo, Burma, have been placed at the disposal of the Government of India in the Home Department.

Major E. J. O'Meara has been appointed a Civil Surgeon at Agra. Major C. Milne, from Jhansi, has been transferred as Civil Surgeon at Mussooree in succession to Major G. T. Birdwood appointed as a temporary measure to Agra. Major Leonard Rogers, C.I.E., has been appointed a Member of the Committee of Management of the Royal Zoological Gardens at Calcutta. Major C. B. Prall, Bengal Presidency, has arrived home from India. Major R. W. Anthony has been appointed Civil Surgeon at Dharwar. Lieutenant R. I. Binning has taken over Medical Charge at Ahmedabad. Major E. S. Peck has assumed charge of the office of Civil Surgeon at Jullundur, relieving Captain H. C. Keates, transferred. Major J. W. D. Megaw, officiating professor of pathology at the Medical College, Calcutta, has been granted privilege leave, combined with furlough, for 15 months.

The services of Captain J. H. Horne have been placed at the disposal of the Government of India for special duty in connexion with the prevention of malarial fevers in Madras Presidency. Captain H. W. Illius, on return from leave, has been appointed Civil Surgeon at Jhansi. Captain I. M. Macrae, officiating superintendent of the Central Prison at Lucknow, has been confirmed in that appointment. Captain W. Gillitt has arrived home on leave of absence from India. Captain R. T. Wells has taken up duty as Superintendent of the District Jail at Dera Ghazi Khan. Captain D. S. Patton has been appointed to officiate as Director of the King Institute at Guindy. Captain F. V. O. Beit has been appointed to the Civil Medical Charge of the Shwebo District, in place of Captain W. Egan, R.A.M.C. Captain M. L. Puri has passed the lower standard examination in the Baluchi language. Captain M. Corry has been appointed Superintendent of the District Jail at Multan, in succession to Captain W. W. Jeudwine. Captain P. S. Mills, plague medical officer at Delhi, has been transferred to Hoshiarpur. Captain H. C. Buckley, plague medical officer at Rohtak, has been transferred to Sialkot. Captain A. J. H. Russell has been granted an extension of five months of his leave of absence on the recommendation of a medical board. Captain M. MacKelvie, officiating civil surgeon at Darbhanga, has been granted privilege leave combined with furlough for one year. Captain E. C. C. Maunsell has joined the Madras Civil Medical Department. Captain H. E. S. Leathes has been appointed to act as personal assistant to the Surgeon-General with the Government of Bombay during the absence on deputation of Captain J. L. Lunham. Captain R. D. MacGregor has received six months' extension of his leave on medical certificate.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Arthur Robertson Brailey to be Staff-Surgeon (dated Nov. 7th, 1911).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant George H. Usmar to be Captain (dated Feb. 24th, 1912). Lieutenant Harry D. Rollinson is confirmed in his rank.

DEATHS IN THE SERVICES.

Colonel Francis Joseph Lambkin, R.A.M.C., at Bloemfontein, on March 8th, aged 54. He entered the army in 1881, and after serving in India and the West Indies was appointed senior medical officer to Lord Dundonald's brigade during the South African war of 1899–1902. He was present at the relief of Ladysmith and at the action at Colenso, at Spion Kop, and other operations, and in the Orange Free

State and Cape Colony (Queen's medal with five clasps and King's medal with two clasps). He was employed as syphilologist on the headquarter staff of India in 1905, and later became lecturer on syphilology at the Army Medical College in London. In 1907 he went on a special mission to Uganda to inquire into the ravages of syphilis there, and in the following year read his well-known paper on the treatment of syphilis by soamin at the meeting of the British Medical Association at Sheffield.

Owing to insufficient time to fully attend to his duties Sir Frederick Treves has retired from the Army Medical Advisory Board and the Nursing Board of Queen Alexandra's Imperial Military Nursing Service, on both of which he has served since their foundation 11 years ago. He has also signified his intention of resigning the chairmanship of the Executive Committee of the British Red Cross Society.

Correspondence.

"Audi alteram partem."

THE VALUE OF PNEUMOCOCCUS VACCINE IN THE TREATMENT OF PNEUMONIA.

To the Editor of THE LANCET.

SIR,—I have been interested in reading Dr. Nathan Raw's article in THE LANCET of March 9th on the above subject, which is a record of experience still much needed on the use of vaccines in pneumonia. I do not share with Dr. Nathan Raw the regret that an auto-vaccine is not always readily obtainable in early pneumonia. In the first place we may be sure in most cases of pneumonia, even in the influenzal and "typho-pneumonia" cases, that the pneumococcus is the predominant poison-organism present, shall I say the organism of first instance, in the pathology of the disease, and a good stock culture is therefore quite acceptable if required. In the second place, I am doubtful of the value of the vaccine in the first days of the disease when the resistance is overwhelmed by the toxic venom of the first onslaught. Thirdly, although it is true that a vaccine can be obtained within a few hours from exudation directly removed by puncture of the hepatised lung, yet these early punctures can only be obtained at considerable hazard, unless the consolidation has advanced to the surface of the lung with great rapidity. In the first days of really desperate cases I am inclined to think, from an experience, however, of one case only, that a serum—Pane's or Merck's—administered with bactericidal intent may be more valuable than a vaccine. At present I advise the vaccine to be held ready for use nearer the crisis, perhaps about the fourth or sixth day, in those cases in which the pneumonia still shows signs of spreading or involving separate parts of the same, or attacking the other lung. For this purpose a vaccine obtained with due care from the sputum of the first days of the disease has the advantage of securing the coöperation of any complicating organisms that may be present. The disadvantage is the very considerable expense often involved in obtaining an autogenous vaccine. An estimate of the organisms present may, however, be made without proceeding to make a vaccine from them, as a guide to the selection of a stock vaccine.

I cannot say that Dr. Nathan Raw's figures show much in favour of the value of vaccines in acute pneumonia. The mortality in his cases, which included 66 cases below the age of 20 and only 4 above that of 60, was a little over 16 per cent., whereas I take the average death-rate of pneumonia, taking all cases, to be about 17 per cent.; and excluding the intemperate, the mentally afflicted, and those over 65 the mortality is 12·5. I do think, however, that vaccines are of value in some cases and at those periods of the disease which I have specified, and it is desirable for them to be in readiness for use in such cases. It is in cases in which there is a tendency for the crisis to be postponed, and in those many cases in which the crisis is followed by a lingering remittent pyrexia, not due to any purulent collection, that vaccines are of undoubted value.

There is one more point on which I should like to enter a *caveat*—viz, the initial dose of vaccine. A 15 or 20 million dose is a more prudent one to begin with, which can be liberally advanced if necessary with close observation of pulse and temperature. I have recently seen a decided reaction with rigor and temperature rising to 105° from even so moderate a dose as 20 millions.

I am, Sir, yours faithfully,

Portland-place, W., March 11th, 1912. R. DOUGLAS POWELL.

THE NATIONAL INSURANCE ACT AND THE HOSPITALS.

To the Editor of THE LANCET.

SIR,—The position of the London hospitals in reference to the admission of patients when the medical benefits of the Insurance Act come into operation is one which is being, or will shortly be, considered by the governing bodies of the hospitals. Presumably they will desire and be entitled to ask for the opinions and advice of their medical staffs on the subject, and seeing the importance of the issues involved it is to be hoped that the members of the honorary staffs will take measures that their advice may be very carefully considered before being given and that they should endeavour to come to some agreement as to what is desirable. I trust, therefore, you will allow me to submit in your columns some of the points which at no distant date will have to be decided upon.

Although the National Insurance Act gives power to the Commissioners to give grants to hospitals, the Chancellor has stated, "It is not proposed to make provisions for institutional treatment," and for a time, at any rate, there will be no provision under the Act for any kind of treatment for persons under 16, nor for emergencies, nor for women, except a very uncertain number, nor will there be any provision for indoor institutional treatment (except for tuberculosis) for any persons whatever, and the amount and duration of "medical benefits" for "deposit contributors" will be very limited. There is, therefore, no reason why the voluntary hospitals should not continue to receive any of the persons or ailments coming under these categories. But under the Act the whole of the male working-class population over 16 years of age, whatever the amount of their earnings, and a large number of other persons, not manual workers, whatever their incomes, will be insured for treatment for such diseases and injuries as do not require *indoor* institutional treatment.

The voluntary hospitals are established and supported for the benefit of persons who are unable to pay for treatment. The insured persons will not only be able to pay, but will have already paid for, and be able to obtain elsewhere, the outdoor treatment they require, and it would be inconsistent for the voluntary hospitals to supply treatment and medicines to such persons who are not in need of them, while declaring that the effects of the Insurance Act will so reduce the support they receive from the public as to force them to close down beds to the exclusion of patients who require the treatment for which they are not insured.

Again, honorary medical officers should not be expected to give their services to persons who have no claim to gratuitous treatment and whom other doctors have received payment to attend. It may be pointed out that some of these persons will be in affluent circumstances, for though the Act empowers the Commissioners to exclude such persons from unlimited "medical benefits" they will be compelled in such cases to hand over to them the estimated money value of their medical benefits. It is therefore suggested that as soon as the medical benefits come into force hospitals should not accept for out-patient treatment persons who, by their insurance, are entitled to receive such treatment elsewhere. The proposal would not involve any departure from the principles on which the voluntary hospitals have always been conducted—viz, the restriction of their treatment to persons who are not able to afford to pay for it. It would involve that the hospitals should recognise that under the Act a large number of persons now qualified to receive outdoor treatment will under the Act cease to have such claim, being entitled to, and able to, receive the treatment they require elsewhere. No alteration in hospital regulations would be required, but only that the present regulations should be acted upon.

The Chancellor in his speech to a deputation of hospital representatives on July 25th, 1911, pointed out that this was the course the hospitals ought to adopt. He said: "The

hospitals should ask, 'Are you insured?' He says 'Yes'; he has no right to come to hospitals." Among the insured persons there will occur cases of doubt or of difficulty in which special advice may be advisable, and it is suggested that such insured persons shall be accepted as out-patients if sent by a medical man for consultative purposes. It may be pointed out that the "deposit contributors" will not be excluded by the proposal above made whenever their medical benefits under the Act lapse or expire. If the proposal here made is adopted by the hospitals, no hardship would occur. No persons would be excluded from hospital relief except from that form of treatment to which they are entitled and able to get free elsewhere. The present overcrowding of hospital out-patient rooms by a large number of comparatively trivial cases would be to the same extent relieved, greatly to the advantages of the patients with more serious ailments, and it is believed there would still be ample material and much better opportunities for clinical teaching.

A saving would be effected in the out-patients' department and the hospitals would continue to receive only persons unable to pay for the treatment they require. They would not be in the danger they are in at present of losing support from the public, who naturally demur at subscribing towards the treatment of persons for whose treatment they have already been taxed. The suggested restriction might at present be limited to males; to exclude insured females would exclude the large class of domestic servants and others, and this would require further consideration. The question as to asking or receiving subventions from Insurance Committees might also be left open, and it would not affect the present proposals.

I am, Sir, yours faithfully,

London, W., March 8th, 1912. SIDNEY PHILLIPS.

DOES CANCER OCCUR IN VEGETABLES?

To the Editor of THE LANCET.

SIR,—In common, I doubt not, with most students of the cancerous process, I have been much interested in speculations as to whether anything of that nature can be produced in vegetable tissues. It is obvious from the beginning that definitions are absolutely necessary in order that we should understand the subject which we discuss; and I would venture boldly to define what we mean by cancerous action to be some influence which promotes, in the first place, a reproduction of tissues, which more or less resemble those natural to the part affected, and secondarily their more or less rapid death. By some such definition we can distinguish between cancer and most forms of chronic inflammation. I have recently been working upon what is called amongst gardeners and foresters the "canker" of trees, &c. It is known to be produced in different trees by different causes. Thus we have the canker in the apples known often as the American blight, canker of the larch known as the larch disease, and canker as it occurs in the oak and many other trees by no special name. In many of these special causes such as the attacks of named parasites, &c., are well recognised. I have, however, been much impressed by the features of similarity which they possess to one another and to cancer, as it occurs in animal tissues.

My object in addressing this letter to you is not, however, to record any new observations of my own, but to ask the attention of your readers to some remarkable and very valuable contributions to our knowledge which have recently been recorded in America under the name of "The Crown-Gall of Plants: its Cause and Remedy."[1] I have read no paper recently which has caused me to regret more definitely that the New Sydenham Society has ceased its labours, for it is one which ought to be promptly reprinted. If I were to record all my own conclusions I should have to mention as mere guesses much that has now been anticipated and established on carefully collected evidence in this "Bulletin." I must not trespass on your pages with any attempt to summarise its conclusions, but must recommend your readers to procure it and to study it carefully. I had come to the conclusion that between canker in vegetables and cancer in animal tissues there was no really fundamental distinction. The paper to which I refer traces what we know as canker to a polymorphic bacterium, the B. tumefaciens. I regret that the condition has received the misleading, or at any rate not instructive, name of Crown-Gall. The growths to which it refers are very common, and abundant opportunities for investigating them will be afforded to us all during the advancing spring. I may probably be able before long to record some facts in detail respecting them, and make some criticisms, and they have no doubt already attracted the attention of some of our British botanists.—I am, Sir, yours faithfully,

Haslemere, Surrey, March 9th, 1912. JONATHAN HUTCHINSON.

[1] The Crown-Gall of Plants: its Cause and Remedy. By E. F. Smith, N. A. Brown, and C. O. Townsend. Washington: Government Printing Office. 1911. A reference may also be made to a most interesting paper on Bacterial Diseases of Plants communicated by Professor M. C. Potter, Sc.D., M.A., to the Journal of Agricultural Science, January, 1912. Mr. Potter quotes freely from Dr. Smith's paper, but contributes valuable material of his own.

THE INTESTINAL FLORA.

To the Editor of THE LANCET.

SIR,—I was much interested by Dr. Distaso's article on the Intestinal Flora, and not less interested in Dr. Edwin Goodall's criticism.[1] My observations in regard to the bacteriology of the intestinal contents have been chiefly concerned with the conditions found in infants and children. At the Infants Hospital, where some 50 babies are constantly under treatment, a bacteriological examination of the intestinal dejecta is made in every case, and in many cases repeated examinations are made. It appears to me that among infants and children there can be no doubt as to the profound pathological influence exercised in certain circumstances by that group of organisms generally known as the colon group. We have gradually arrived at methods of bacteriological diagnosis which permit of the conditions being precisely appreciated and appropriately treated. In cases of "colon toxæmia" pure cultures which have a powerful influence in rendering the intestinal conditions inimical to the growth or action of the colon organisms are systematically administered. The power of the cultures and their beneficial influence have been demonstrated on many occasions, notably in cases where relapses have followed the suspension of the cultures, while rapid improvement has ensued as a result of their renewed administration. At the present time more than one-half of the infants in the hospital are being treated by pure cultures, the nature and dose of the culture varying according to the organisms attacking the infant and their degree of virulence. In all cases of "enteritis" and allied conditions the importance of arriving at a bacteriological diagnosis is, in my opinion, paramount. I may cite two cases out of many in illustration.

I saw a child, aged 6 years, suffering from acute colitis, at Taunton in consultation with Dr. L. H. C. Birkbeck. The whole of the colon was acutely tender; there was marked hæmorrhage from the large intestine, the blood being bright red and mingled with mucus. The condition was found to be due to the bacillus enteritidis sporogenes. A pure culture of the streptococcus lacticus in an extremely active condition was prepared (the particular strain of this organism employed being the one known in the Infants Hospital Research Laboratory as "No. 52"). Within three days of the first administration all the acute symptoms had ceased, and in a week the child was convalescent. He made a rapid and uninterrupted recovery.

A child, aged 12 months, suffering from severe intestinal toxæmia, was seen by me at Westgate-on-Sea in consultation with Dr. Heaton. The child could not take milk in any form without the gravest intestinal disturbance, and his condition had given rise to much anxiety. In this instance we had to deal with a virulent colon bacillus. The power of the organism was such that it curdled milk (at 38° C.) in five hours with the production of much gas, while in other respects it gave marked evidence of its virulence. To effectively combat the powerful organisms attacking the infant a culture containing several organisms was prepared. This case required careful watching owing to the power of the antagonistic cultures and the necessity of avoiding a too sudden or too great revolution in the intestinal conditions. The result was most satisfactory. The child made a rapid and striking recovery; it was out of danger in a week, and in another week was well able to digest a fairly rich milk mixture.

In both these cases I am satisfied that but for the bacteriological diagnosis and consequent treatment the patients

[1] THE LANCET, Feb. 24th, 1912, p. 496; March 9th, p. 684.

would have done very badly. It was not possible for either of these children to have recovered without, at the best, a prolonged illness, had they not received the immediate and powerful assistance of cultures specially prepared to attack the organisms attacking them.

I would, however, strongly emphasise two points. 1. Each case must be studied on its merits; to treat cases of intestinal toxæmia with stock cultures is worse than useless. It is as dangerous as the proper treatment is beneficial. 2. The administration of the cultures must be adjusted as to dosage, according to the precise requirements of the cases; while as soon as the indications are met the administration should be suspended. As a rule it is better that the suspension should be gradual rather than complete and sudden.

The dosage is the question which is most difficult at the present time. It is therefore necessary to proceed with caution, as up to the present our information in regard to the indications for dosage is very inadequate. In all cases the dietetic treatment is of great importance. The diet commonly provided for infants and young children frequently acts as a direct encouragement of the pathogenic organisms. Some articles of diet act so powerfully in this direction that their administration may go far to neutralise the action of the cultures. I am, Sir, yours faithfully,

Harley-street, W., March 9th, 1912. RALPH VINCENT.

THE CAUSATION AND PREVENTION OF TOXIC SYMPTOMS FOLLOWING THE ADMINISTRATION OF SALVARSAN.

To the Editor of THE LANCET.

SIR,—I have read with interest the paper by Dr. J. McIntosh, Dr. P. Fildes, and Mr. H. Dearden, appearing in THE LANCET of March 9th. I note that their conclusions confirm those obtained by Major T. W. Gibbard, Major Harrison, and Lieutenant Cane, of the Royal Army Medical Corps, published in the *Journal of the Royal Army Medical Corps* for January, 1912. These officers reported that the preparation of the salt solution on the morning of the injection was the most important consideration, and had the greatest effect in reducing the severity of the reaction, and that this was still further enhanced by the fresh distillation of the water, but that the use of chemically pure sodium chloride had no advantage over common salt.

It has always been my custom to prepare and autoclave the salt solution immediately before use. It is made with distilled water, which for the last year I have filtered immediately before the salt is added. The water has only been distilled once a week, and is kept in a large glass jar, from which it is drawn off as required. I have had very few occurrences of toxic symptoms, except in cases of florid secondary syphilis, and out of close on 200 injections I have not recorded rigors in certainly more than ten, vomiting has been only very occasional, and the temperature is rarely raised above 100° F.

For the last two months, in view of the opinion of many trustworthy authorities, I have used only freshly distilled water for the preparation of the saline solution. The result is practically the same, and I have obtained a marked reaction only in cases of florid secondary syphilis. My experience leads me to the conclusion that Schreiber's theory for the occurrence of reaction (viz., the liberation of endotoxins from killed spirochætæ) is true for the great majority of cases. It appears to me that the incidence of mortality as the result of treatment with salvarsan is so small that it is probably due to some rare accident rather than idiosyncrasy in the way of intolerance to the drug. I have on one occasion had to throw away a tube of salvarsan which was cracked and the vacuum destroyed, and the contents of which, therefore, were doubtless partially or completely decomposed and highly toxic. It has occurred to me that some of the reported fatal cases may have been caused by the injection, not of salvarsan, practically non-toxic in present dosage, but of a toxic substance resulting from a crack or fault in the glass ampoule. I give, as a rule, two injections of 0·6 grm. of salvarsan intravenously, with an interval of only 48 hours, and yet have at present met no symptoms of toxicity that can be definitely traced to the drug.

I filtered the distilled water originally not with any idea of getting rid of any bacteria which might be present, but because of the possibility that foreign material might have found its way into the distilled water. I imagined that, as the saline was autoclaved prior to use any bacteria present and toxins produced by them would be destroyed by the process and rendered harmless, and it was for purely mechanical reasons that I filtered the distilled water prior to adding the salt and autoclaving the solution. As it appears to be the dead bodies of the organisms rather than the toxins which they produce which cause the symptoms of toxicity, it would seem that if the distilled water were passed through a filter sufficiently fine to prevent the passage of micro-organisms, this would meet the case and a fresh distillation each day would be unnecessary.

I am, Sir, yours faithfully,

HUGH WANSEY BAYLY,
Pathologist to the London Lock Hospitals, &c.
Upper Berkeley-street, W., March 10th, 1912.

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 9th, pp. 637–640, appears a paper on the causation of the toxic symptoms that may follow the use of salvarsan. This paper is in the main a *résumé* of various theories that we have recently shown to be unsupported by sound evidence. We ask you, therefore, kindly to publish the following statement.

In July, 1911, Wechselmann advanced the theory that salvarsan fever is necessarily due to gross infection of the saline demonstrable at the time of injection. He stated that the accident of fever can be avoided by using solutions made with freshly distilled water, and the truth of this statement he fully proved in 150 cases. His theory, however, of the cause of salvarsan fever was not sound, because, as we showed in December last, fever often follows the injection of water or saline that contain practically no organisms. We showed, on the contrary, that water fever, salt fever, and, in consequence, salvarsan fever, are often due to contamination of the water by a heat-stable filtrable body that bears no relation to the degree of infection capable of demonstration at the time of injection. Salt fever and salvarsan fever are often, as we showed, nothing more or less in fact than water fever. This one of us had already pointed out six months previously at Birmingham, though we did not then know the true cause of water fever to be the heat-stable body we have since described. In January of this year, however, Dr. McIntosh and his colleagues resuscitated Wechselmann's theory to which they had already subscribed four months after its appearance as a result of independent work. In the interval they had found that gross infection of their reagents was demonstrable before the addition of salt instead of afterwards. Hence the theory was modified to this extent. A fortnight ago, at a meeting of the Pathological Section of the Royal Society of Medicine,[1] we again proved to demonstration that neither Wechselmann's theory nor its adaptation by the workers at the London Hospital is sufficient to explain either salt fever or salvarsan fever, and we showed that no adequate controls had been carried out by any of these four observers. We pointed out that the theory rested solely on the assumption that unbroken protein, and suspensions of organisms derived from the air and then grown on water or saline, are necessarily capable of producing fever after single injections. And we gave full and precise technical details of numerous experiments which clearly showed that this assumption can no longer be justified. We also illustrated our points by the exhibition of 13 charts. Dr. McIntosh was actually present during our communication, and took part in the discussion that followed. He then confessed that he had not carried out the control experiments we had shown to be essential. We therefore do not understand him when he says, in referring to our work, that he "awaits the publication of precise technical details." The experiments he now gives in THE LANCET in support of Wechselmann's theory are in no sense control experiments, as we pointed out in the discussion referred to. The practical object of our communication was to show that demonstration of the sterility of any given solution is no guarantee that it does not contain the toxic colloid

[1] THE LANCET, March 2nd, 1912, p. 579.

we described. The frequent part played by this body in producing symptoms of toxæmia after injection of sterile water or saline is an indisputable fact that can be verified at will.

We are, Sir, yours faithfully,

E. C. HORT.
W. J. PENFOLD.

Harley-street, W., March 12th, 1912.

THE SIGNIFICANCE OF THE SYMPTOMS IN CASES OF DUODENAL ULCER.

To the Editor of THE LANCET.

SIR,—Dr. Saundby's criticism of my article in your issue of to-day consists of some uninteresting remarks about myself, to which I shall make no further reference; of a statement in which, as he himself suggests, he misrepresents what I said, quoting a passage to which I did not specially refer; and, lastly, of some experiences of his own which confirm in many particulars what I actually did say.

Dr. Saundby's retort that "it is as unscientific to assume that a thing does exist until it has been seen" sounds clever, but will not stand a moment's investigation. There are many things the existence of which has not only been assumed but proved without their ever having been seen at all.

I am, Sir, yours faithfully,

C. MANSELL MOULLIN.

Wimpole-street, W., March 9th, 1912.

FUNGI FOUND IN TROPICAL BRONCHOMYCOSIS.

To the Editor of THE LANCET

SIR,—Dr. R. Craik, in his letter to THE LANCET of Jan. 13th, applies some courteous criticisms to me for having stated that endomyces albicans liquefies gelatin, and also for having created—in his opinion—some superfluous species; he suggests that endomyces pinoyi and saccharomyces krusei are one and the same organism. As regards the action of endomyces on gelatine it must be noted that some authors (Hewlett, &c.) state that the organism liquefies the medium, others affirm the reverse. The discrepancy is most probably due to the fact that the various observers were dealing with different species. The term endomyces albicans has probably been used to cover a number of species in the same manner that the term B. coli has for years been applied to numbers of different intestinal bacteria when only a few fermentation tests were carried out.

From the reactions given in the table Dr. Craik is justified in suggesting that endomyces pinoyi and saccharomyces krusei are the same organism, as endomyces pinoyi is given in the table as not fermenting maltose. This is a mistake which I much regret crept in in my manuscript in tabulating the results. As a matter of fact endomyces pinoyi always produces acid and gas in maltose, while saccharomyces krusei never ferments this sugar: the two organisms, therefore, cannot be identical.

I am, Sir, yours faithfully,

A. C. E CASTELLANI, M.D. Florence.

Clinic for Tropical Diseases, Colombo, Ceylon, Feb. 10th, 1912.

THE LATE DR. W. R. HUGGARD.

To the Editor of THE LANCET.

SIR,—We desire to give effect to the widely expressed wish that a suitable memorial should be raised to the late Dr. Huggard. The object we have in view is twofold—firstly, to place in the Queen Alexandra Sanatorium (an institution which largely owes its existence to his self-sacrificing philanthropy) a memorial tablet, if possible with a medallion portrait of Dr. Huggard; and secondly, to create a Huggard Benevolent Fund in aid of British invalids at Davos who are in need.

We believe that it is not generally realised how many of the patients who go there fail in their pursuit of health through lack of means. The proposed fund will be invested in the names of trustees, and the income spent under the management of a carefully appointed local committee. It would be administered in close connexion with the institution known as the English Nurses' Home, with which it may, if events prove it to be expedient, be afterwards incorporated and united.

We are confident that a memorial on these lines is not only the most fitting tribute that can be paid to the memory of one who lived so much for others, but it is that which would have given the greatest satisfaction to Dr. Huggard himself.

Subscriptions should be sent to Mr. Edward C. Simmons, 74, Cheapside, E.C., or to the London Joint Stock Bank, 120, High Holborn, W.C., crossed "Huggard Memorial Account."

We are, Sir, yours faithfully,

BALFOUR OF BURLEIGH.
HENRY ANGST (British Consul-General, Zürich).
ARNOLD F. BILL.
J MITCHELL BRUCE.
W. J SCUDAMORE EMERY.
B. HUDSON (British Consul, Davos).
GERALD F. MCGAREL HOGG.
ROBERT W. PERKS.
R. DOUGLAS POWELL.
EDWARD C. SIMMONS.
D. A. F. VESEY.
E. S. WOODS (English Chaplain, Davos).
H. C. WRINCH.

Cheapside, E.C., March 5th, 1912.

THE RECENT OUTBREAK OF POLIOMYELITIS AT STOKE RIVERS.

To the Editor of THE LANCET.

SIR,—Mr. G. Adkins in his letter on March 2nd concerning the recent outbreak of poliomyelitis at Stoke Rivers criticises the statement made in your issue of Feb. 17th, "that among the whole 36 cases there is not a single case of definite poliomyelitis." Mr. Adkins refers to Dr. Reece's paper in the Epidemiological Section of the Royal Society of Medicine for further details. On reference to this other paper I find the statement: "In this community of 119 persons there were 36 attacks of poliomyelitis which were more or less definite, although *only three developed paralysis*, two suffered from facial paralysis, and one, a lad aged 17, remains paralysed in both legs. In addition to the 36 there are nine others who may possibly have suffered in a minor degree." This does not furnish much additional information.

Your article said, "Before accepting this epidemic as one of poliomyelitis far more proof would be required." Possibly Mr. Adkins has this proof, and if so it would be extremely interesting if he would furnish a complete account of the Stoke Rivers epidemic, with a note on the present condition of the patients remaining paralysed.

It is unfortunately not possible to carry out the serum test for poliomyelitis on these patients owing to the absence of experimental animals in this country, though this might be done in France, Germany, or Austria. Such a test would at once decide if the cases above referred to were due to the virus of poliomyelitis.

I am, Sir, yours faithfully,

M.D.

March 4th, 1912.

NATIONAL IDEALS.

To the Editor of THE LANCET.

SIR,—In your review of "New Tracts for the Times" last week you refer to Dr. Horton's discussion of National Ideals. For the main purport of this theme, has at any time the relation of the nation to the Empire been better expressed than by Claudian, in those wonderful lines where he deals with the relation of Rome to her Empire?

> Haec est, in gremium victos quae sola recepit,
> Humanumque genus communi nomine fovit,
> Matris, non dominae ritu; civesque vocavit
> Quos domuit, nexuque pio longinqua revinxit.

"This is she who alone took the vanquished to her bosom and cherished all mankind by one common name, ruling them as mother, not as mistress, who named those whom she conquered citizens, and bound them to her for ever in the bond of righteousness." This, be it remembered, was written by one of the conquered.—I am, Sir, yours faithfully,

OXONIENSIS.

March 11th, 1912.

THE POPLAR MEDICAL UNION.—Dr. C. K. Toland, the secretary of this union, has informed the members by circular that a voluntary committee, not wholly medical, has agreed to provide medical treatment for school children in Poplar under the London County Council scheme, a course that is in opposition to a scheme drawn up by the joint committee of the Metropolitan Division of the British Medical Association. Dr. Toland's circular appeals to the members not to accept service under the voluntary committee.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Hospital for Sick Children and Women, Bristol.

THE annual meeting of the subscribers of this institution was held on March 4th under the presidency of the Lord Mayor. The medical report stated that during 1911 the out-patients numbered 4656, and 77 women and 730 children had been admitted as in-patients, an increase compared with 1910. The financial statement showed that the income amounted to £4683, and that the expenditure was £5205. The committee in its report alludes with regret to the death of Dr. John Beddoe, who had been connected with the hospital since 1866, and adds "that the committee was always proud of the connexion between the hospital and one who had made a world-wide reputation."

The Exeter Education Committee.

The school hygiene subcommittee has recommended the Exeter education committee to appoint a surgeon-dentist at a salary of £250 per annum to treat the teeth of school children, and suggested that premises and equipment for his use should be provided at an expenditure of about £60. It further recommended that about £100 should be expended on the treatment of ringworm. At the meeting of the committee held on Feb. 28th it was decided, after some discussion, to adopt the proposal of the subcommittee.

King Edward VII. Memorial Dispensary, Plymouth.

The first annual meeting of the subscribers of the Didworthy Tuberculosis Dispensary, Plymouth, was held last week, under the presidency of Dr. R. Hogarth Clay. The medical report stated that during the year 320 patients had been treated. The medical officer (Dr. C. D. Lindsey) stated "that he had given tuberculin in a small number of cases, and while he was not able to point to any great success so far, he was sure benefit had resulted in a certain number of cases." The financial statement was unsatisfactory, and Mr. Cecil Wills, who presented the figures, said that unless more subscriptions were received the dispensary would have to be closed. It was decided that in future the institution should be called the "King Edward VII. Memorial Dispensary."

The Royal Cornwall Infirmary, Truro.

The late Mr. T. L. Dorrington, of Truro, has bequeathed about £6500 to the Royal Cornwall Infirmary, for the establishment and maintenance of a convalescent home for females at Perranporth. The institution is to be called "The Dorrington Home," and is to be worked on similar lines as the Passmore Edwards Convalescent Home for Men at Perranporth, which is also in connexion with the Royal Cornwall Infirmary.

March 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Morison Lectures: Royal College of Physicians, Edinburgh.

THESE lectures were delivered in the hall of the Royal College of Physicians on Feb. 26th and 26th and March 1st. The lecturer this year was Dr. J. J. Graham Brown, who had selected for his theme "Certain Aspects of Aphasia." The subject was dealt with in great detail, and yet most lucidly and interestingly. There was a good and appreciative audience at each of the lectures. The lectures are to be published, and will prove a valuable contribution to the literature of the subject dealt with, for they will be found to bring much scattered knowledge together, carefully sifted, analysed, and arranged, and suitable for practical clinical application.

Professor Simon Flexner in Edinburgh.

Professor Flexner, of the Rockefeller Institute, New York, Cameron Prizeman in Therapeutics of the Edinburgh University, lectured in the M'Ewan Hall of the University on March 4th to a large audience of students, professors, and other members of the profession. The lecturer took for his subject "Specific Local Therapeutics of Infection," dealing mainly with the serum treatment of epidemic cerebro-spinal meningitis. On the following day he delivered a clinical lecture to the combined university and extra-mural students of clinical medicine in the large theatre of the Royal Infirmary. The theatre was crowded. The lecturer discoursed on acute anterior poliomyelitis.

Appointment of Assistant Physician to the Edinburgh Royal Infirmary.

The managers of the Edinburgh Royal Infirmary at their meeting on March 4th appointed Dr. John Eason to be an assistant physician. A vacancy occurred because Dr. Byrom Bramwell's term of office as a full physician has expired. There were seven candidates, and the contest has been a very keen one.

Scottish Medical Insurance Council.

This body was to have had its first meeting on March 15th, but it has had to be indefinitely postponed owing to the disorganisation of the railway service consequent upon the coal strike. Meantime the lull in insurance matters of necessity continues.

Disjunction of Montrose Royal Infirmary from the Royal Asylum.

In view of the disjunction of Montrose Royal Infirmary from Montrose Royal Asylum, owing to the introduction of a new charter for the asylum, the special committee appointed by the asylum and infirmary board represented to the representatives of the district lunacy boards and parish councils of Forfarshire and Kincardineshire that a capital sum of £10,000 would be required to yield a sum of £350, the amount of an annual grant from the asylum to the infirmary. The petitioners for popular representation on the board, however, submitted an offer of £9350 cash down, in lieu of all rights of the infirmary in the corporation, and after conference the special committee recommended yesterday to the managers of the board the acceptance of that sum. The meeting unanimously approved the action of the committee.

Handsome Donation to Brechin Infirmary.

A sum of £5000 has been handed to Brechin Infirmary by the trustees of the late Mr. David Jamie.

Fire at the Aberdeen Royal Asylum.

An alarming outbreak of fire took place at the Aberdeen Royal Asylum last week and did considerable damage to the buildings. About 4 o'clock in the morning the night fireman discovered that part of the woodwork at the rear of the engine room had become ignited. In a few seconds a considerable area of the roof was in a blaze. The asylum horn was blown, calling out the fire brigade in the institution. The hydrants and other extinguishing appliances were brought into operation, and soon an impression was made on the flames. The city fire brigade had also been telephoned for, and the combined action of the brigades soon had the flames completely extinguished. The damage amounts to £200, and fortunately there was no damage done to the engines. From the engine-rooms the asylum is heated, and the means of cooking are also supplied from it, while the electric switchboard is also situated in the buildings. Dr. W. Reid, interviewed after the fire, said that the precautions provided against fire in the Royal Asylum were so complete that it was practically impossible for any outbreak to assume serious dimensions. The demonstration given by the staff in dealing with the outbreak was sufficient evidence of the safeguards provided for the absolute safety of the inmates. There had been no alarm amongst the patients, and few of them knew that anything unusual had happened till several hours after.

Aberdeen Medical Men and the National Insurance Act.

A provisional medical committee has been chosen for the burgh of Aberdeen to deal with contract practice in the city and other matters relative thereto. Dr. J. Munro Moir (Inverness) was nominated for membership of the Advisory Committee, which is to meet the Joint Insurance Commissioners in London.

Aberdeen Royal Infirmary.

The newly elected board of directors of the Aberdeen Royal Infirmary met on Feb. 29th. Mr. George M. Cook was unanimously elected chairman of the board for the ensuing year. Miss Elizabeth Edmonston, matron of the Becket Hospital, Barnsley, Yorkshire, was appointed matron of the infirmary in room of the late Miss Macnaughton. Intimation was given of a legacy of £1000 to the infirmary by the late Mr. David Jamie.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Substitute's Fees in the Poor-law Service.

THE amount of remuneration to be paid to a medical man doing duty as locum-tenent in the Poor-law service gives rise to many wrangles. The difficulty arises from the fact that the onus is put on the relieving officer of providing a substitute when there is necessity, while the Local Government Board does not permit him to make a bargain binding on the guardians. In a recent case Mr. W. R. G. Hamilton, of Edenderry, accepted duty, having been assured of remuneration at the rate of a guinea a day by the relieving officer, but the Local Government Board refuses to sanction payment at that rate.

Professorship of Surgery in the Royal College of Surgeons.

The Council of the Royal College of Surgeons is about to make the appointment of a Professor of Surgery. Like the other professors, his appointment is subject to annual re-election, but with the proviso that he shall not hold office for more than five years.

Medical Man's Life on the Aran Islands.

Probably few medical men in the Kingdom have a more adventurous life than the dispensary medical officer of the Aran Islands, situated in Galway Bay. There are three inhabited islands, and the only means of navigation from one to the other is by the "curragh," or hide-boat, a frame of wood covered by stretched cow-hide or canvas. One afternoon recently, at about 5 o'clock, the medical officer at Kilronan received a wire requesting his services immediately in a maternity case at Innismaan. Although sky and sea looked threatening, he succeeded in procuring a boat's crew, and set out in a curragh to cross the four and a half miles of storm-swept sea. After considerable difficulty Innismaan was reached and the boat was got ashore by the aid of willing islanders. Halfway across on the return journey the storm became a hurricane, and the craft was at the mercy of the waves. The doctor and crew gave themselves up for lost, but happily some trawlers were at anchor, and to these the crew held fast waiting for a lull. From that evening to the following Friday no curragh or steamer called at the island or left it.

Royal Victoria Hospital, Belfast: Resignation of Dr. Walton Browne.

At a meeting of the board of management of the Royal Victoria Hospital, Belfast, held on March 6th, a letter was read from the senior surgeon, Dr. J. Walton Browne, resigning his post. Dr. Browne, who has been surgeon to the institution for a period of over 36 years, was then appointed consulting surgeon to the hospital, a special resolution being passed thanking him for his valuable services and deeply regretting his resignation. Mr. Robert Campbell, assistant surgeon, will, it is believed, be promoted without a contest to the vacant surgeoncy, and for Mr. Campbell's position there is a keen canvass among four of the younger medical men of the Belfast Medical School.

The Newry Hospital.

At a meeting of the committee of this hospital on March 11th, the Earl of Kilmorey, K.P., presiding, a resolution was passed expressing regret at the retirement of Mr. B. Beamish as medical officer, and passing a cordial vote of thanks to him for his valuable services to the hospital during 18 years. The successor to Mr. Beamish is to be paid the same salary, £100, and the election will take place on April 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Antivenomous Serum in the Treatment of Scorpion Stings in Children.

IN the regions of Ben Gardane and Zarzis scorpion stings often assume a particularly dangerous character. From 1906 to January, 1911, inclusive, Dr. Lefèvre, assistant médecin-major, has collected from the mortality statistics of the Sud six deaths due to this cause. Of the six children two received no attention for their injury; the rest were treated with injections of permanganate, or hypochlorite of sodium, or by cauterisation with zinc chloride. One of them had even received an injection of antivenomous serum. Having personally witnessed two fatal cases and being struck by the inefficiency of the local mode of treatment, Dr. Lefèvre injected 10 c.c. of Calmette's antivenomous serum into all the patients irrespective of their condition. The injection was always made between one hour and three hours after the sting. Not one out of eleven patients thus treated showed any signs of poisoning. This can hardly have been all a matter of coincidence. He concludes that in all cases of scorpion stings in children the injection of antivenomous serum ought always to be practised as soon as possible in association with the local method of treatment by cauterisation. Cauterisation, indeed, is often a matter of difficulty, for the patient is frequently incapable of indicating precisely the part stung, the mark is often imperceptible, and there is thus danger of cauterising the wrong place.

The Horace Wells Prize.

A prize of 500 francs is offered, to be adjudged in 1915, to the author of the best essay dealing with a notable improvement in the present methods of surgical anæsthesia, or to the discoverer of an approved anæsthetic agent or to the inventor of apparatus, procedures, or methods markedly facilitating narcosis. Essays must be addressed to M. Quincerot, president of the Comité Horace Wells, 28, rue de Moscou, Paris. No restriction is placed as to the profession or nationality of the candidates, but all the essays must be written in French and signed with a motto or device, the names and addresses of the authors being enclosed in a sealed envelope bearing the same device as their respective essays.

Aluminium Apparatus for Fractures of the Limbs.

M. Raoul Deslonchamps showed at the Société de Médecine de Paris on Feb. 24th some apparatus in sheet aluminium for the treatment of fractures of the limbs. Since aluminium is permeable to the X rays it is possible to control by radioscopy the exact position of the bony fragments. If they are in bad position the author uses small bags of indiarubber into which air is forced, thus exercising where required a pressure that is easily borne.

Sanitary Measures in Parliament.

A new party has been formed and has opened a provisory bureau in the Chamber of Deputies to aid the struggle against tuberculosis. This body has examined the legislative measures to be undertaken to combat tuberculosis, among others the organisation of instruction on tuberculosis, the establishment of cheap markets, and the necessity for notification. The anti-alcohol party in the Chamber of Deputies has also met under the presidency of M. Joseph Reinach. It urges that the Hygienic Commission should bring before the Chamber at the earliest moment possible a measure for the total suppression of absinthe, and should again present a measure to limit the number of places for the retailing of intoxicants.

The French Committee for the next International Congress of Medicine in London in 1913.

A preparatory meeting of the French committee took place on March 3rd in the great amphitheatre of the Faculty of Medicine of Paris under the presidency of Professor Landouzy, *doyen* of the Faculty of Medicine. Each of the 22 French sections nominated its bureau for the forthcoming congress. The presidents, vice-presidents, and secretaries were appointed and will proceed to prepare the lists of subjects in their respective sections to be presented to the Congress. There was a large attendance at the meeting, giving rise to the hope that the French participants in the congress will be numerous, and will include the greatest names in French medicine. The Bureau of the French Committee of Organisation consists of Professor Landouzy, president; Professor Debove, Professor Hayem, Professor Reclus, and Professor Lucas Championnière, vice-presidents; Dr. Raoul Blondel, secretary-general; and M. Piere Masson, treasurer.

An Army Consultative Sanitary Committee

M. Millerand, the Minister of War, has modified the name and composition of the sanitary committee attached to the Ministry of War. The successive decrees of 1882, 1888, and 1901, not being in absolute accordance, give it an irregular character. Moreover, of the members composing the committee two did not belong to the sanitary service, but were borrowed from other arms or services, and only one member

belonged to the Sanitary Corps of the colonial troops. Henceforth, the Sanitary Committee will revert to its former and true title of Consultative Sanitary Committee and will no longer admit outsiders. The number of medical inspectors of colonial troops on the committee is to be raised from one to two. This measure will provide for the sanitary service of these special troops a representation more in accord with its importance. The committee will thus consist of 11 members, of whom eight at the most will be selected from the medical inspectors general or medical inspectors of the corps of military sanitation, and two at least from those of the sanitary corps of the colonial troops in addition to the pharmacist inspector of the Sanitary Military Corps.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Surgical Treatment of Phthisis.

Professor F. Sauerbruch, who has occupied the chair of surgery at the University of Zürich since the death of Professor A. Krönlein, has published a paper on the Surgical Treatment of Phthisis. The operative treatment of tubercular cavities of the lung has hitherto been anything but encouraging. According to Dr. Tuffier's statistics only 1 patient out of 27 was healed; most of them died rapidly. Runeberg later reported on about 19 fatal cases. In 1888 Quincke and Carl Spengler, independently of each other, proposed mobilising the diseased lung by resection of several ribs. Several cases were successfully operated on by Carl Spengler, Bier, Landerer, Turban, and von Mikulicz. Chondrotomy, a new method proposed by Freund, has been performed only seven times. Forlanini and Murphy introduced operative pneumothorax, with Brauer seconding them.[1] The Davos doctors have reported satisfactorily on the results provided that the other lung was not extensively diseased. Professor Sauerbruch reports on his experiences with thoracoplasty as introduced by Friedreich in advanced cases of phthisis. Rapidity and operation *à deux temps* are absolutely necessary in view of the feeble condition of the patients and the danger of fatal collapse. Professor Sauerbruch has performed 50 operations on 32 patients, of whom only 1 succumbed to the operation; 8 were suffering from bronchiectasis, and 24 from phthisis. Two patients died respectively four and nine months after operation; 2 were cured, 2 almost cured, the rest improved more or less. The method recommends itself for very severe cases with one-sided localisation where climatic, dietetic, and medicinal treatment cannot effect a cure.

Severe Hæmorrhage from an Ovarian Cyst.

Dr. Tschudy, surgeon to the Theodosianum Hospital at Zürich, reports a case of severe hæmorrhage from an ovarian cyst, which simulated appendicitis. He has previously read a paper on two similar cases before the Zürich Medical Society in 1910. A patient, aged 32, was seized with severe abdominal pain at 9 A.M. on Sept. 23rd, 1911, which disappeared after a couple of hours. Acute return at 3 and 8 P.M. On admission to the hospital at 9 P.M. the pain was still acute and localised above the symphysis pubis. Temperature 37·2° C. (99° F.), pulse 64. Pregnancy and a tubal hæmorrhage being excluded, the diagnosis of appendicitis seemed the most probable. Laparotomy revealed a considerable amount of blood in the abdomen and oozing from an ovarian cyst of the size of an apple. The adiposity of the patient had prevented this tumour being felt on examination. There were about 3 pints of blood in the abdomen. Uneventful recovery ensued and the patient was dismissed from hospital after three weeks. Such cases are very rare. Bürger reported one in the *Zentralblatt für Gynækologie* in 1904. As in other cases of abdominal hæmorrhage, the pulse-rate was low.

Zürich, March 11th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—The annual meeting of members and subscribers will be held at the college, 22, Chenies-street, W.C., on Friday, March 22nd, at 5.15 P.M., when Mr. James Cantlie will be in the chair.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Deaths of Medical Men in the United States and Canada.

IN 1911, there were 2145 deaths among medical men in the United States and Canada, or, estimating that the number of medical men in these two countries to be 140,000, the rate was 15·32 per 1000. For the nine previous years the death-rates were as follows: 1910, 16·96; 1909, 16·2; 1908, 17·39; 1907, 16·01; 1906, 17·0; 1905, 16·36; 1904, 17·14; 1903, 13·7; and 1902, 14·74. The average annual mortality was 16·11 per 1000. The age at death varied from 23 to 99, with an average of 59 years and 10 months. The chief causes of death in the order named were: cerebral hæmorrhage, "heart disease," senility, pneumonia, external causes, and kidney disease.

Montreal Death-rate in 1911.

During the year 1911 there were 9974 deaths in the city of Montreal, 5110 males and 4864 females, thus giving a death-rate of 21·39 per 1000 of the population. This is 1·01 less than in 1910. The deaths of children under five years of age numbered 5355, being 53·69 per cent. of the general mortality, or a decrease of 0·50 per cent. over that of 1910. Measles claimed 74 in 1911, against 155 in 1910; scarlet fever, 76 against 118; diphtheria, 133 against 136; typhoid fever, 124 against 192; phthisis, 736 against 785.

Professor Adami.

Quite recently Dr. J. G. Adami, professor of pathology in McGill University, Montreal, was offered the chair of pathology in the Northwestern University, Chicago, U.S.A., which is better endowed. Canadians are exceedingly glad to learn that the services of Professor Adami are not to be lost to the Dominion. His loss would have been felt not only by McGill and Montreal but the entire country. Dr. Adami came to McGill in 1892 as professor of pathology. He was for three years pathologist to the Montreal General Hospital, and is now head of the pathological department of the Royal Victoria Hospital. He has always taken a leading part in public health matters, particularly in the campaign against tuberculosis.

Hebrew Tuberculosis Hospital for Montreal.

Recently a week was set aside by the Hebrews of Montreal to conduct a campaign for $25,000 necessary for the annual maintenance of the Mt. Sinai Sanatorium. Some time ago the Hebrews of Montreal secured a site for a sanatorium near Ste. Agathe and plans for a new building were obtained. The farmhouse on the grounds served at first as a temporary hospital for urgent cases, but for lack of funds this had to be closed, and the patients placed in boarding houses. As soon as the maintenance fund is found a well-organised society will campaign for funds for the new building at a cost of $35,000. The results will tell what Jewish charity will do in the direction of fighting the "white plague."

Clinical Records of the Insane.

Dr. W. J. Robertson, superintendent of the Hospital for the Insane at London, Ontario, has recorded 500 consecutive admissions to this institution from Jan. 1st, 1908, to June 6th, 1910. Prior to this time no systematic attempt was made to obtain the life-history of each patient, no conferences of the staff were held, no reports and no clinical notes were on record. Of the total 500 cases, 16 were admitted twice during the period above mentioned, so that 484 individuals are dealt with. The males were 251 and the females 233. Family history: In 153 cases, or 31 per cent., insanity was reported as having occurred in some relative. In 40 cases, or 8·26 per cent., alcoholism in some member of the family is reported, and in 17 of these cases alcoholism and insanity were found combined. Personal history: In 57, or 11·7 per cent., a history of alcoholism was found, the patients not being confirmed alcoholics, but having drunk to excess at some period of their lives. In only 10 cases was a history of syphilis found (Wassermann reaction not taken). Of the dementia præcox cases, 89, or 44·5 per cent., were discharged recovered or improved; 13, or 6 per cent., died; 91, or 45 per cent., still in residence. Of the manic-depressive insanity, 50, or 83 per cent., were discharged as recovered or improved; 2, or 3·3 per cent., died; 7, or 11 per cent., still in residence. Melancholia

vera, 17, or 56 per cent., recovered or improved; 6, or 20 per cent., died; 6, or 20 per cent., still in residence. Seniles: 14, or 23 per cent., discharged improved; 18, or 30 per cent., died; 23, or 39 per cent., still in residence. General paralysis: 3, or 15 per cent., discharged improved (remission); 13, or 65 per cent., died; 3, or 15 per cent., in residence. Alcoholism: 11, or 91 per cent., discharged recovered or improved; 1, or 9 per cent., still in residence. Summary: 233 cases, or 48 per cent., have been discharged as recovered or improved; 8 discharged as unimproved; 67, or 13 per cent., have died; 5 eloped; 4 were transferred; 5 were deported; 162, or 33 per cent., are still in residence.

New Hospital Journal in Toronto.

Dr. W. A. Young, publisher of the *Canadian Journal of Medicine and Surgery* at Toronto, has launched a new hospital journal, *The Hospital World*, which is to be an international hospital medium, with head office in Toronto, and branch offices in Buffalo, N.Y., U.S.A., and London, England. The first number was issued in January, and is a very creditable production. It is understood that Dr. J. N. E. Brown, late superintendent of the Toronto General Hospital and secretary of the American Hospital Association, will shortly assume editorial control.

Tuberculosis Sanatoriums in Newfoundland.

The sons of Sir R. G. Reid, St. John's, Newfoundland, have offered to the Government of Newfoundland to equip a building in St. John's to be used as a sanatorium or hospital for the treatment of tuberculosis on condition that the Government provides a suitable site. In a letter to the Premier of Newfoundland, Sir E. P. Morris, Mr. W. D. Reid, the president of the Reid Newfoundland Company, states that he estimates this will cost $50,000. In addition to this Mr. Reid states that his brothers and himself will, on sites provided by the Government, build, furnish, and equip in each of the 16 extern electoral districts of the island a sanatorium or hospital for the same purposes, but smaller in size and estimated to cost about $3000 each, or $50,000 altogether, which, when fully equipped, along with the institution for St. John's city, will be handed over to the Government unconditionally for management and control. When established these sanatoria will be known as "The Reid Sanatoria."

The Needs of Asylum Medical Officers.

The board of management of the Protestant Hospital for the Insane at Verdun, Quebec, have forwarded a memorial to the government of that province asking that consideration be given to a scheme of pensioning medical officers after a sufficient length of time in the asylum service. This memorial points out that owing to the increased number of insane in Quebec more and more medical officers have additional onerous work thrust upon them. It is also pointed out that the salaries of the medical service of these institutions are inadequate to provide for the officers making provision for the future, and that while their duties are very arduous they are also often dangerous. Physicians to these institutions should be placed on a plane with other ranks of the civil service in which pensions are granted.

March 1st.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Women and the Medical Profession in India.

IN order to encourage women desirous of entering the medical profession to study for the M.B. and C.M. degree of the Madras University, the Madras Government has resolved to award annually three stipends of 25 rupees per month to young women who undertake to study for their degree. The stipends will be allotted each year by the Provincial Committee of the Countess of Dufferin Fund, and may be awarded either to students who have already passed the intermediate examination in arts or those who are reading for it. The maximum tenure of stipend will be seven years. The Government is also of opinion that as a further inducement to obtain these higher qualifications enhanced salaries should be given those possessing it. The salaries range from 100 to 200 rupees, with the allowance ranging from 25 to 50 rupees, when the holders of qualifications are in independent charge.

An Incident in Anti-malarial Measures in India.

The following true story of the well-meaning manager of a tea estate in Sylhet may interest your readers. He was greatly concerned that his coolies should escape the ravages of malaria, and posted himself in all the literature on the subject, from Laveran to Bentley. He waged relentless war on every species of mosquito, and then started to make his people immune. On pay days, as each coolie came up for his pay, he administered a five-grain dose of quinine, which the coolie had to swallow on the spot. One night after this treatment he was summoned to the lines to see a coolie who was suffering from severe cinchonism. He could make nothing of the case and sent post-haste for the district doctor. "What have you been giving him?" asked the medical man. "Quinine," replied the planter. "How much?" "Five grains." "Nonsense, man, he must have swallowed fifty to be afflicted in this way." And so it turned out. The coolie had come up again and again to the pay office to draw the pay of certain absentee friends and had taken the quinine each time without a murmur, so as not to upset the sahib.

Feb. 14th.

Obituary.

CHARLES PARNHAM SKRIMSHIRE, M.R.C.S. ENG., L.S.A.

Mr. C. P. Skrimshire, late medical officer of health of the Brynmawr urban district and the Llanelly rural district, died from cerebral hæmorrhage at his residence, "Sandhaven," Weston-super-Mare, on Feb. 22nd, in his sixty-eighth year. He was the son of the late Mr. George Skrimshire, surgeon, of Holt, Norfolk, and received his medical education at St. Bartholomew's Hospital, where he was senior scholar in 1869. In the same year he took the "College and Hall," and shortly afterwards commenced practice in Blaenavon, Mon. He held many public appointments, being senior surgeon to the Blaenavon iron works, medical officer of health for the Brynmawr urban and the Llanelly rural districts, medical inspector under the Factories Act at Blaenavon, and public vaccinator for Brynmawr. Mr. Skrimshire was an ardent Freemason, and had been Master of the Kennan Lodge. He was a distinguished Volunteer, and had been brigade-surgeon of the South Wales Infantry Brigade, and was granted the Volunteer Decoration for long service.

He was very popular in Blaenavon, and had been president of the Eastern Valleys Medical Association. Mr. Skrimshire lately retired from active work and had taken up his residence at Weston-super-Mare, where he was highly respected, especially by the poor, to whom he was most generous; and much sympathy is felt for his widow and children. The funeral took place at the Weston cemetery on Feb. 26th, the service being performed by the Rev. C. Hodder, assisted by the brother of the deceased, the Rev. Canon Skrimshire.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. F. Zachrisson, lecturer on surgery in the University of Upsala.—Dr. E. G. A. Landergren, lecturer on physiology in the Stockholm Medical School.—Dr. A. Negri, *privat-docent* of General Pathology and Bacteriology in the University of Pavia.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At a recent meeting in connexion with St. Mark's branch of the St. John Ambulance Association, Liverpool, Mr. Percy Gordon Sheppard, L.M.S.S.A. Lond., was presented by the members with an inlaid ink-stand as a mark of their appreciation for his services as honorary instructor.—At a recent meeting in Padstow the Hon. Mrs. Prideaux Brune, on behalf of the Padstow (Cornwall) "Ladies' First-aid and Home Nursing Class," presented Mr. Frank Harvey, M.R.C.S. Eng., L.S.A., with a handsome pair of old Sheffield plate candlesticks as a mark of appreciation for his services as honorary lecturer

THE NATIONAL INSURANCE ACT.

THE GENERAL MEDICAL COUNCIL AND THE COMMISSIONERS.

AT the last meeting of the Executive Committee of the General Medical Council the President, Sir Donald MacAlister, reported upon the communications which had passed between the Assistant Secretary of the Joint Committee of the National Insurance Commissioners and the Registrar of the Council with reference to the proposed conference on Feb. 2nd between the Commissioners and representatives of the medical profession. The President said that before replying to the Commissioners' invitation he consulted with the members of the National Insurance Bill Committee of the General Medical Council and with the authorities at the Privy Council Office. It will be remembered that the answer sent by direction of the President on Jan. 30th explained that since the Council would not meet before June, nor its Executive Committee before the end of February, it was impracticable to procure the formal appointment by the Council of six representatives to confer with the Insurance Commissioners on Feb. 2nd. The letter added that the Council would, however, give its best consideration to any communication transmitted to it by the Commissioners and would be ready to afford them such information as they might require on matters lying within its province.

MEMORIAL FROM THE WIVES OF PRACTITIONERS.

The Executive Committee of the General Medical Council also received a memorial with regard to the National Insurance Act from the Doctors' Wives Defence Movement, Manchester. This memorial was sent in response to an intimation that the Council would be prepared to receive petitions presented in accordance with the standing orders. It was prefaced by a statement by the honorary secretary, Mrs. Thomas Gregory, on the effect of the Bill upon the wives, families, and dependents of medical men. The memorial received 836 signatures in three days and was worded as follows:—

We the undersigned, wives of duly registered medical men of Manchester, Liverpool, Oldham, Blackburn, and other towns and places in England and Wales, desire to present to the President and Members of the General Council of Medical Education and Registration of the United Kingdom this protest against the National Insurance Bill as at present framed. We would urge you to give the following statements your careful and deliberate consideration as adversely affecting our interests. The Bill will cause decided loss of income, while creating greater demands upon our resources, thus giving rise to reduced education for our children, reduced life insurance, loss of goodwill or practice value. The Bill offers no provision or compensation against such losses. Our grave anxiety is for the welfare of our children, as it would mean in many cases absolute destitution for the wife and children in the event of a husband's incapacity or death.

THE MEDICAL FEDERATION.

The Medical Federation, Limited, whose provisional registered office is at Lion Chambers, Broad-street, Bristol, has issued a circular letter to medical practitioners, which states that the time has now come when members of the medical profession must, in their joint and several interests, unite, and that the success of any scheme to protect the interests and to guarantee the fair treatment of the profession, both now and in the future, can only be ensured by unanimous and concerted action. For this purpose any organisation which is formed must be not merely a local but a national measure; in fact, a federation of all medical practitioners. The circular alleges that although the British Medical Association already exists to protect the interests of the profession, for various reasons it has never in the past succeeded in adequately safeguarding its members. It can give no guarantee of protection to its members other than one conditional upon the support obtained by a voluntary subscription list, and a perusal of its Memorandum will show that no power is reserved to use this fund to indemnify or compensate its members. The Association has for years been striving to obtain the necessary powers, but the only way in which it can do so is by coöperation with an existing body which has those powers. For this reason the Medical Federation, Limited, has been formed with the most ample powers, and the fact is emphasised that the company is formed in no spirit of hostility or opposition to the British Medical Association, but with the express object of strengthening its weak points—of being its complement. The purpose of the company is to secure the fair treatment and protection of the members of the medical profession, to ensure adequate remuneration for their services, to oppose the passing of legislation hostile to them, and generally to safeguard their interests with due consideration for the rights of the public. The present directorate is provisional only. The members of the company will elect their own directors out of their own number, and every member will be represented on his local or district committee, as well as in the central governing body. The entrance fee is £2 2*s*. and the annual subscription 25*s*.

Certain points in the Medical Federation's circular have been considered by the newly formed State Sickness Insurance Committee of the British Medical Association. The statement that the Association "could give no guarantee of protection to its members other than one conditional upon the support obtained by a voluntary subscription list" has been referred to counsel, and the Association has been advised that the Association's Defence Fund can be lawfully used for indemnification and compensation. Representatives of the Federation have, we understand, been invited to attend the next meeting of the State Sickness Insurance Committee for the purpose of clearing up misapprehensions and defining the relations between the two bodies.

Medical News.

ROYAL SOCIETY OF ARTS.—At a meeting of the Royal Society of Arts held on March 6th, with Mr. James Swinburne in the chair, Mr. T. Thorne Baker read a paper on Some Modern Problems of Illumination. Almost at the outset he spoke of the differing biological effects produced by various parts of the spectrum, as proved by the luxuriant growth of certain bacteria in the two regions corresponding to the chlorophyll bands, the remainder of the spectrum being practically destitute of those organisms. He then said that the preference of many families of bacteria and also of yeast for certain colours tended to show that the artificial light employed for the habitations of human beings should presumably resemble that to which they were normally accustomed, and should, therefore, be spectroscopically equivalent to the daylight derived from white clouds. Mr. Baker here described in much detail the analysis of illumination by spectro-photography and the methods of preparing screening filters by means of which two dissimilar illuminants may be made to resemble one another in their effects. For this method of analysing light the concave grating spectrograph was superior to the prism spectrograph, because in the former the dispersion throughout the spectrum was proportional to the wave length, whereas in the latter the green, yellow, and red regions were all cramped up together, and therefore tended to appear far more luminous than actual measurement showed them to be. Two forms of spectro-photometer were also described, as well as a contrivance for use in industrial work where colour-mixing or matching was part of the ordinary routine, with the result that standard daylight illumination was available for working by in all weathers and by day or night. A number of metal filament lamps (usually tungsten) were fixed in the top of a box, the bottom of which was formed by a gelatin-on-glass screening filter. After passing through this filter the rays were diffused by a piece of ground-glass, and then fell on the table where the work of mixing or matching colours was in progress. Mr. Baker here suggested that this method of imitating normal daylight would be useful in the illumination of art galleries and picture exhibitions. For this purpose incandescent tungsten filaments were the best source of light; it was unlikely that normal daylight could ever be matched with the illumination from a mercury vapour lamp. The Moore and Cooper-Hewitt lamps were probably only the forerunners of many other lamps depending on the luminosity of electrically excited gases, notably neon and helium. Pure neon was exceedingly luminous when subjected to high tension electrical discharges, and M. Claude claims to be able to produce in a day 100 litres, which would suffice for the manufacture of 1000 tubes of neon of 1000 candle power each. The tubes at present made for commercial purposes must be supplied with alternating current. The lighting power is about 200 candles per metre of tube, and the consumption of electricity for the luminous portion of the tube is about 0·45 watt per candle. Neon rays are a rich golden red. Rarefied pure helium gas gives an intense light

of whitish-yellow hue, somewhat similar to that of the flame of some of the lighter burning oils. Helium vacuum tubes 7 centimetres in length and 2 millimetres in bore, with terminal bulbs containing aluminium electrodes 25 millimetres in diameter, have quite recently been adopted by the Bureau of Standards at Washington as the standard unit of illumination.

A CONVERSAZIONE will be held at the West London Hospital, Hammersmith, on Wednesday next, March 20th, at 8.30 P.M., when the staff of the Post-Graduate College will be "at home" to their friends.

NEW CHILDREN'S HOSPITAL FOR VIENNA.—A wealthy Viennese Jew, David Ritter von Gutmann, has given the Jewish community 3,000,000 kronen (£120,000) to build a hospital for children. This is to be ready for occupation within two years.

MEDICAL SOCIETY OF LONDON.—The 139th anniversary dinner of this society was held on March 6th at the Whitehall Rooms, Hotel Metropole, under the chairmanship of Dr. J. Mitchell Bruce, the President. There was a large and distinguished gathering, and the guests included the presidents of many sister societies and associations. The chairman, in proposing the toast of the evening, touched briefly on the long history of the Medical Society of London, and congratulated it upon the keenness and earnestness of its debates and the success of its less formal clinical evenings. He paid a tribute to Dr. A. E. Garrod's Lettsomian lectures, and referred to the loss which the society had sustained by the death of Pavy, Hughlings Jackson, Allchin, and Lister, who all had been office-bearers. Mr. J. Bland-Sutton replied in a humorous speech which much amused his audience. He related the case of a rhinoceros with intestinal obstruction which did not yield to an ounce of croton oil in a bun, but was relieved by an enema containing a pint of castor oil and a bottle of whisky in six gallons of soap and water. The result was immense, and the beast survived for 23 years. Dr. T. B. Hyslop proposed the health of the guests and kindred societies, and told some good stories. The reply was entrusted to Mr. Rickman J. Godlee, President of the Royal College of Surgeons of England, and Lieutenant-Colonel Sir William Leishman, R.A.M.C., President of the Society of Tropical Medicine and Hygiene. Mr. Godlee announced that it was Lister's wish that his medical books should pass into the possession of the Medical Society. Sir William Leishman said that he represented the youngest of medical societies, which, however, had already a membership of 606. In his opinion the multiplicity of such societies showed that medical men were gregarious. The health of the President was very warmly proposed by Sir Lauder Brunton, and the toast was received with musical honours. Dr. Mitchell Bruce, in his reply, asked the company to drink the health of the honorary secretaries, and Dr. J. W. Carr and Mr. Edred Corner each responded before the close of a most successful evening.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Medical Treatment of School Children.

A SUM of £60,000 appears in the Education Estimates this year for the medical treatment of school children. This is the first time that such a grant has ever been proposed by the Board of Education, but the authorities there have come to the conclusion that if the medical inspection of school children is to be attended with the most fruitful results medical treatment must be combined with it. On Thursday, March 7th, Mr. WHITEHOUSE, in the course of a debate on the vote on account, asked the representatives of the Board of Education to explain their attitude on this subject. There were many engaged in education, he said, who felt that medical inspection of elementary school children was almost useless until it was made possible for medical treatment to be carried out at the schools and under the control of the authorities attached to the schools. Mr. TREVELYAN, the Parliamentary Secretary to the Board of Education, drew attention to the fact that £60,000 had been put down on the estimates for the purposes of medical treatment. He mentioned that regulations would issued under which that sum would be spent, and he hoped that it would result in increased activity on the part of the local authorities in carrying out what both sides of the House regarded as a necessary expenditure to raise the standard of the health of school children.

Employment and Superannuation of Asylum Officers.

Several Bills dealing with the position of asylum officers are before the House of Commons. The one which was recently introduced by Lord WOLMER not only seeks to amend the Asylum Officers' Superannuation Act, 1909, but proposes to limit the hours of employment of officers and servants in asylums. The terms of the Bill are identical with the amended text of last year's measure. As was noted at the time, the Select Committee of the House of Commons came to a compromise. The Bill, whilst allowing for elasticity in administration and for emergencies, proposes to institute a maximum 70 hours week for asylum attendants. The Bill further gives to female established officers or servants of the first class a right to superannuation after 25 years' service. Clause 6 lays down that the power of the visiting committee to remove an officer or servant shall not be delegated to any officer, but general rules "may provide for enabling the medical superintendent or any other person specified in the rules to suspend any officer or servant from the service of the asylum pending the decision of the visiting committee as to whether he shall be dismissed or not."

Sir CHARLES NICHOLSON has introduced an Asylum Officers' Superannuation Bill which differs in certain respects from the measure brought forward by Lord WOLMER. It does not deal with the hours of asylum attendants, and the clause with reference to dismissals and suspensions does not find a place in it. It is therefore purely a measure dealing with superannuation. Sir CHARLES NICHOLSON has the support of Colonel LOCKWOOD, Mr. CROOKS, Mr. MILLAR, Mr. HARRIS, and Mr. NANNETTI in bringing forward his Bill.

Abolition of Vivisection Bill.

The object of Mr. LANSBURY'S Abolition of Vivisection Bill is to prohibit under heavy penalties experiments and demonstrations on live animals. The preamble of the Bill sets forth that "it is expedient to amend the law relating to cruelty to animals in the cases of animals which for medical, physiological, or pathological or scientific purposes, or for the purpose of testing former discoveries, or for the acquirement of manipulative skill, or for the illustration of lectures in medical schools, hospitals, colleges, or elsewhere are subjected to inoculations or to other experiments calculated to cause pain or suffering except for the purpose of curing or alleviating any injury or disease from which such animal is suffering." Clause 2 of the Bill lays down that "it shall not be lawful to subject any animal to vivisection, that is to say, to perform on any live animal with or without the use of anæsthetics, any experiment or demonstration or inoculation of a nature to cause pain or suffering to the animal, either directly or in its after-effects, for any pathological, surgical, physiological, or other scientific purpose, or for the acquirement of manipulative skill.

The Report of the Royal Commission on Vivisection.

The final report of the Royal Commission on Vivisection was issued to Members of the House of Commons on Tuesday, March 12th. The Commissioners say that, having regard to the witnesses who have appeared before them, there can be no doubt that the great preponderance of medical and scientific authority is against the opponents of vivisection. They come to the conclusion that experiments on animals adequately safeguarded by law and faithfully administered should not be prohibited by legislation. The recommendations of the Commission are summarised as follows:—

1. An increase in the inspectorate.
2. Further limitations as regards the use of curare.
3. Stricter provisions as to the definition and practice of pithing.
4. Additional restrictions regulating the painless destruction of animals which show signs of suffering after experiment.
5. A change in the method of selecting and in the constitution of the Advisory Board to the Secretary of State.
6. Special records by experimenters in certain cases.

There are reservation memoranda.

Vivisection of Dogs.

By a curious coincidence the publication of the report of the Royal Commission on Vivisection was followed on Tuesday evening by a discussion in the House of Commons on a motion dealing with the vivisection of dogs. Mr. MCKENNA, the Home Secretary, pleaded, however, the impossibility of any decision being arrived at on the matter until due consideration had been given to the report of the Royal Commission on Vivisection, and the House was counted out.

Naval Medical Service.

Mr. CHURCHILL, the First Lord of the Admiralty, in his statement explanatory of the Naval Estimates, referred to the recent changes in the organisation and conditions of service of the medical staff which had followed upon the recommendations of the Durnford Committee.

The General Medical Council's Accounts.

The accounts of the General Medical Council for 1911, and also those of the branch councils and of the Dental Registration Fund, have been presented to the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 6TH.

Holiday Feeding of Necessitous Children.

Mr. LANSBURY asked the Prime Minister whether he was aware of the suffering caused amongst tens of thousands of poor children by the inability of local authorities to incur the expenditure necessary to feed such children during holiday times; and whether, with a view to

putting an end to such suffering during the forthcoming holidays, he would arrange for sufficient time being given to allow the House to pass the necessary amending Bill to enable such feeding to take place.—Mr. ASQUITH answered: I am not aware that any Bill for this purpose is before the House. The Government, however, are prepared to give favourable consideration to the principle.

Sanatoriums in Scotland.

The Marquis of TULLIBARDINE asked the Secretary to the Treasury what proportion of the £1,500,000 available for the purpose of providing sanatoriums would be available for Scotland, and whether it would be allocated amongst counties and burghs on the basis of population, or whether it would be pooled.—Mr. MASTERMAN furnished the following written reply: In accordance with Section 64 (1) of the National Insurance Act, the proportion of the total sum available in accordance with that section for providing or maintaining grants to sanatoriums and other institutions which is allocated to England, Scotland, Ireland, and Wales respectively will depend upon their populations as shown in the Census of 1911. The allocation of the sum so available for Scotland will rest primarily with the Scottish Local Government Board, and I understand is now under their consideration.

Maternity Benefit under the Insurance Act.

Mr. ROWNTREE asked the Secretary to the Treasury whether under Section 8 (6) of the National Insurance Act an insured woman was entitled to sickness benefit in respect of her confinement for four weeks, even if she was not incapable of work during the whole of that period.—Mr. MASTERMAN wrote in reply: An insured woman will receive maternity benefit of 30*s.* on confinement. An insured married woman will receive sickness benefit for so long as she is incapable of work. The Factory and Workshop Act, 1901, prohibits the employment in a factory or workshop of any woman within four weeks after childbirth, but if the woman is certified to be incapable of work for a longer period she will continue to receive sickness benefit.

THURSDAY, MARCH 7TH.

Telephones and Tuberculosis.

Dr. C. ADDISON asked the Postmaster-General whether he had caused any inquiry to be made into the dangers which had been stated to arise from the use of telephones by persons suffering from open tuberculosis; and, if so, whether he was in a position to state the result of his inquiry.—Mr. H. SAMUEL replied: A prolonged investigation was undertaken by Dr. H. R. D. Spitta, at my request and has recently been completed. It extended not only to telephones used in public call offices, but also to certain telephones which were installed at a sanatorium for the regular and exclusive use of patients in all stages of tuberculosis. As a result Dr. Spitta reports that in his opinion "the transmission of tuberculosis through the medium of the telephone mouthpiece is practically impossible." I propose to issue a full statement to the press, as the subject is naturally one of considerable public interest.

Illness at Dartmouth Naval College.

Colonel BURN asked the Secretary to the Admiralty whether steps could be taken to ensure extra assistance at Dartmouth Naval College in times of excessive sickness, so as to prevent the hours of labour of the cadets' servants being unduly extended, as happened during a recent epidemic.—Mr. MACNAMARA replied: It is already the practice to provide for the exigencies of abnormal sickness by a temporary increase in the numbers of nurses and sick-berth ratings allowed to the Royal Naval College. On the occasion in reference, ten qualified female nurses were sent to Dartmouth and one additional medical officer. With regard to the suggestion that the hours of labour of the cadets' servants were unduly extended, the fact is that special arrangements had to be made for the employment of cadets' servants on night duty, each servant taking one hour's duty every fourth night for a period of 19 nights in all.

Medical Treatment of School Children.

Lord HENRY CAVENDISH-BENTINCK asked the President of the Local Government Board whether in cases where treatment of children was prescribed by school medical officers and the parent was unable, by reason of circumstances, to pay the cost of such treatment, the board of guardians was bound to provide such treatment for the child if it was not undertaken by the education authority; and whether he would by circular or otherwise, call the attention of boards of guardians to their duties in this respect; and whether the cost, if defrayed, would be medical relief, which did not disfranchise the parent.—Mr. BURNS answered: It is the duty of boards of guardians to relieve destitution, and, as pointed out in the circular to guardians on the administration of out-door relief, a person may properly be regarded as destitute who is unable to provide for himself the particular form of medical attendance or treatment of which he is in urgent need. The principle would appear to me to apply to the case of children who need medical treatment which the parent is unable to provide. I realise that the relative position of the boards of guardians and the local education authorities in this matter is one of some difficulty, and I have already had the matter under consideration. I may add that medical relief of the kind referred to afforded by boards of guardians would not involve disfranchisement of the parent.

MONDAY, MARCH 11TH.

The National Insurance Act.

Mr. F. HALL (Dulwich) asked the Secretary to the Treasury whether he was now in a position to state the date on which it was proposed that the National Insurance Act should come into force; whether such date would relate to the whole of the United Kingdom; and, if not, whether the working of the measure would be suspended in those districts which had shown themselves to be not yet ready for its provisions.—Mr. MASTERMAN said, in reply: I know of no reason why the health insurance part of the National Insurance Act should not come into operation on the date given in Section 115 of the Act—namely, July 15th, 1912. It is not intended that that date should vary in different parts of the United Kingdom. The Board of Trade as at present advised proposes to bring the unemployed insurance part of the Act into force on July 15th next for the United Kingdom as a whole.

Sick Absences in the Post Office Staff.

Mr. DAWES asked the Postmaster-General whether his attention had been directed to the number of sick absences, due mainly to nervous complaints, among the female counter clerks and telegraphists during the year 1911; whether he was aware that during the month of January, 1912, as many as 52 women out of a staff of 195 were absent for varying periods, and that during last month over 50 women were incapacitated for duty; whether he would state what additions had been made to the East Central district staff in consequence of the admitted understaffing a short time since; and whether he would institute a further inquiry into the general conditions of working and the nature of the duties imposed, with a view to removing the causes of the sick absences.—Mr. H. SAMUEL answered: My attention has been called to this matter. I am glad to say that apart from a small proportion of the staff who required prolonged sick leave the general health during 1911 of the female counter clerks and telegraphists employed in the East Central district was satisfactory in spite of the excessive heat experienced last summer. The amount of sick leave due to nervous ailments represented rather less than 14 per cent. of the total sick absence. The figures 52 and 50 quoted by the honourable Member include some other officers than counter clerks and telegraphists and are overstated by about 20 per cent. Five officers were added to the reserve staff during 1911 and the question of creating a further additional appointment is under consideration. In the circumstances I do not think that the inquiry referred to by the honourable Member is necessary.

The Certification of Lunatics.

In the course of the debate on the Vote of Account,

Mr. BURNS (President of the Local Government Board) said that where it was possible to have an inclusive salary for a Poor-law medical officer to certify lunacy it should be done, and as vacancies occurred by death or otherwise he was doing that. The certification of ordinary lunatics was a matter for the Lord Chancellor and Home Office.

WEDNESDAY, MARCH 13TH.

Sanatoria in Scotland.

Mr. FREDERICK WHYTE asked the Secretary for Scotland whether Scotland's share of the sum available for the erection of sanatoria under Section 64 of the National Insurance Act would be apportioned strictly according to the population of different areas; and whether he could give an assurance that necessitous districts in the Highland and Islands would not be allowed to suffer owing to the sparseness of their population.—Mr. MCKINNON WOOD replied: The matter is now under the consideration of the Local Government Board for Scotland in view of the terms of the section referred to, and my honourable friend may rest assured that the varying circumstances and conditions of different localities in Scotland will not be overlooked.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX, London.

Acromegaly. A Personal Experience. By Leonard Portal Mark, M.D., late President of the West London Medico-Chirurgical Society, and Pathological Draughtsman to St. Bartholomew's Hospital. Price 7*s.* 6*d.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BISHOP, E. STANMORE, F.R.C.S. Eng., has been appointed Honorary Consulting Surgeon to the Victoria Memorial Jewish Hospital, Manchester.

BROWN, R. CUNYNGHAM, M.D. Durh., has been appointed Deputy Commissioner in Lunacy for Scotland.

BUTLER, WILLIAM, M.B., M.S. Glasg., has been appointed Deputy Medical Officer of Health to the London County Council.

CAMPBELL, G. F., M.B., B.S. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Bangor District of the county of Down.

MCGREGOR, J. G., M.B., B.S. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Castletown District of the county of Caithness.

MEADEN, CHARLES, M.D., B.S. Durh., has been appointed Medical Officer for the Fremington, Newton Tracey, and Tawstock Districts by the Barnstaple (Devon) Board of Guardians.

O'HARA, M. C., L.R.C.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Clara District of King's County.

PEREIRA, JOSEPH ANTHONY WENCESLAUS, M.D. Brux., L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the Exeter Lying-in Charity.

PRICE, PHILIP SEYMOUR, M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Physician to the Margaret-street Hospital for Consumption.

SEDDON, ALBIN, L.R.C.P. & S. Edin., L.F.P.S. Glasg., D.P.H. Edin., has been appointed Medical Officer of Health of Frome (Somerset).

THOMPSON, PETER, M.D. Vict., has been appointed Dean of the Medical Faculty of Birmingham University.

TURNBULL, ROBERT CYRIL, M.D. Lond., has been appointed Medical Superintendent at the New Asylum, Colchester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN, KINGSEAT ASYLUM.—Assistant Medical Officer. Salary £150 per annum, with board, &c.

AGRA, UNITED PROVINCES, INDIA, DUFFERIN HOSPITALS AND FEMALE MEDICAL SCHOOL.—Female Senior Doctor. Salary £26 13*s.* 4*d.* per mensem, with free quarters.

ALBERT DOCK HOSPITAL, Connaught-road, E.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing. Also House Surgeon. Salary £50 per annum, with board, residence, and washing. Each for six months.

BARNSLEY, BECKETT HOSPITAL.—Second House Surgeon, unmarried. Salary £100 per annum and all found.

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and attendance.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Second and Third House Surgeons. Salaries £80 and £75 per annum respectively, with board, rooms, and laundry.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES.—Clinical Assistant. Salary at rate of 52 guineas per annum.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £100 per annum.

BRADFORD CITY BABIES' WELCOMES.—Medical Officer (female). Salary £250 per annum.

BRENTFORD UNION INFIRMARY, WORKHOUSE AND SCHOOLS.—Second Assistant to Medical Superintendent, unmarried. Salary £125 per annum, with apartments, rations, washing, &c.

BRISTOL EYE HOSPITAL.—House Surgeon. Salary £80 per annum, with board and residence.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Junior Resident Officer. Salary £90 per annum, with rooms and attendance.

BURY ST. EDMUNDS, WEST SUFFOLK GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and laundry

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Pathologist. Salary at rate of £250 per annum.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—House Physician. Salary £80 per annum, with board, residence, and laundry.

CANCER HOSPITAL (FREE), Fulham-road, S.W.—Assistant Pathologist. Salary £350 per annum. Also House Surgeon for six months. Salary £70 per annum.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £150 per annum, with apartments.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Clinical Assistant.

CLIFTON, YORK, NORTH RIDING ASYLUM.—Second Assistant Medical Officer. Salary £150 per annum, with board, apartments, washing, and attendance.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £90 per annum, with rooms, board, washing, and attendance.

DEWSBURY AND DISTRICT GENERAL INFIRMARY.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.

DORCHESTER COUNTY ASYLUM.—Second Assistant Medical Officer. Salary £200 per annum, with board, &c.

DORCHESTER, DORSET COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

DREADNOUGHT HOSPITAL, Greenwich.—Two House Physicians and Two House Surgeons, each for six months. Salary £50 per annum, with board, residence, and washing. Also Medical Registrar.

DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Salary £100 per annum, with board, residence, attendance, and washing.

DUNDEE ROYAL INFIRMARY.—Medical Assistants.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Clinical Assistant.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Physician. Also House Surgeon. Salary at rate of £75 per annum in each case, with board, residence, laundry, &c.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, London, S.E.—House Physician. Salary at rate of £75 per annum, with board, residence, and washing. Also Clinical Assistants.

FRIMLEY, BROMPTON HOSPITAL SANATORIUM.—Medical Superintendent. Salary £500 per annum, with board and residence.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Surgeon.

GREENOCK INFIRMARY.—Assistant House Surgeon. Salary £40 per annum, with residence.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with rooms, board, and washing.

HEREFORDSHIRE GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £120 per annum, with board, apartments, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.—Assistant Physician.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—House Surgeon, unmarried, for six months. Salary £30, with board, residence, &c. Also Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board and residence, &c.

JERSEY POOR-HOUSE AND INFIRMARY (HÔPITAL-GÉNÉRAL).—Medical Officer. Salary £250 per annum.

LIVERPOOL HOSPITAL FOR CANCER AND SKIN DISEASES, Myrtle-street.—Honorary Surgeon.

LIVERPOOL, STANLEY HOSPITAL.—House Surgeon.

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £120 per annum, with rooms, attendance, board, and washing.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board and residence.

MANCHESTER CORPORATION.—Assistant Medical Officer of Health. Salary £250 per annum, with board, lodging, and residence.

MERTHYR TYDFIL UNION WORKHOUSE.—Assistant Medical Officer. Salary £150 per annum, with apartments, rations, laundry, and attendance.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Senior and Junior House Surgeon for six months. Salaries at rate of £100 and £85 per annum respectively, with board, attendance, and laundry.

NAVAL FORCES IN THE UNITED KINGDOM.—Dental Surgeon. Salary £1 per day.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Casualty Officer, unmarried, for six months. Salary £60 per annum, with board, lodging, and washing.

PRESTON ROYAL INFIRMARY.—Senior and Junior House Surgeons, unmarried, for six months. Salaries £80 and £60 per annum respectively, with board, residence, and washing.

READING, ROYAL BERKSHIRE HOSPITAL.—Medical Registrar, Surgical Registrar, and Pathologist. Salary by arrangement.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL EAR HOSPITAL, Soho.—House Surgeon, non-resident. Salary £40 per annum. Also Honorary Assistant Anæsthetist.

ROYAL HALIFAX INFIRMARY.—Senior House Surgeon, unmarried, Salary £120 per annum, with residence, board, and washing. Also Third House Surgeon, unmarried. Salary £80 per annum, with residence, board, and washing.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—House Physician for six months. Salary at rate of £60 per annum, with board, lodging, and washing.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Appointments.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—Radiographer. Salary 25 guineas per annum.

SHEFFIELD ROYAL INFIRMARY.—Junior Resident Medical Officer. Salary £60 per annum.

SHEFFIELD UNIVERSITY.—Demonstrator in Experimental Physiology. Salary £200 per annum.

SHREWSBURY, SALOP INFIRMARY (COUNTY HOSPITAL).—House Physician. Salary at rate of £70 per annum, with board and apartments.

SINGAPORE MUNICIPALITY INFECTIOUS DISEASES HOSPITAL, STRAITS SETTLEMENTS.—Resident Medical Officer. Salary £400 per annum with free quarters.

SOUTHAMPTON WORKHOUSE INFIRMARY, Shirley Warren.—Resident Assistant Medical Officer. Salary £130 per annum, with apartments, rations, washing, and attendance.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—House Physician. Salary £82 per annum, with board, residence, and laundry.

SUNDERLAND CHILDREN'S HOSPITAL.—Resident Medical Officer for six months. Salary £80 per annum, with board, residence, and laundry.

SUNDERLAND ROYAL INFIRMARY.—Two Junior House Surgeons and House Physician for six months. Salary £80 per annum in each case, with board, residence, and laundry.

TEIGNMOUTH HOSPITAL, S. DEVON.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

TUNBRIDGE WELLS, ROYAL BOROUGH.—Medical Officer of Health. Salary £500 per annum.

WANDSWORTH UNION.—District Medical Officer. Salary £100 per annum.

WESTERN GENERAL INFIRMARY, Marylebone-road, N.W.—Honorary Physician.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Surgical Officer. Salary £125 per annum, with board, apartments, and laundry. Also Resident Medical Officer. Salary at rate of £100 per annum, with board, rooms, and laundry.

YORKSHIRE, NORTH RIDING COUNTY COUNCIL EDUCATION COMMITTEE.—Senior Assistant School Medical Officer. Salary £300 per annum.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Tranent, in the county of Haddington; and at Holywood, in the county of Down.

Births, Marriages, and Deaths.

BIRTHS.

BENNETT.—On March 10th, at East Bergholt, Suffolk, the wife of H. G. Bennett, M.B., of a daughter.

WINTER.—On March 11th, at John of Gaunt's, Lincoln, the wife of Edward Stuart Winter, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

MARRIAGES.

DONALDSON—BERESFORD.—On March 7th, at the Church of St. Peter and St. Paul, Harlington, Middlesex, Sam Donaldson, L.R.C.P., M.R.C.S., to Helen Maud, younger daughter of Lieutenant-Colonel G. W. Beresford.

MCCLURE—BRYCE.—On March 9th, at Brompton Parish Church, James McClure, M.D., F.R.C.S., to Annie Margaret Jardine (Rita), only daughter of the late Charles Chalmers Bryce and of Mrs. Bryce.

MANBY—BRUCE.—On March 12th, at St. Andrew's, Westminster, E. P. Manby, M.D., D.P.H., to Mary, widow of C. W. A. Bruce, F.L.S.

DEATHS.

LAMBKIN.—On March 8th, at Bloemfontein, Colonel F. J. Lambkin, R.A.M.C.

STEVENS.—On March 7th, 1912, at Tunbridge Wells, Emma, wife of G. J. B. Stevens, aged 52.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

WHO WAS DR. WINTER?

To the Editor of THE LANCET.

SIR,—In your leading article last week on the modern interpretation of the Hippocratic Oath you refer to the exchange of bitter epigrams between Dr. George Cheyne and Dr. Winter, as well as to Dr. Garth's well-known "Dispensary." Dr. George Cheyne is obviously the physician (1671-1743) to whom a small place is allotted in the National Dictionary of Biography, but Dr. Winter I cannot trace. Who was Dr. Winter? I am, Sir, yours faithfully,

March 11th, 1912. M.D.

*** Dr. Winter is only known to us as the author of the following verses addressed to Dr. Cheyne, in reference to that physician's advocacy of vegetarianism:—

Dr. Winter to Dr. Cheyne.

Tell me from whom, fat-headed Scot,
Thou didst thy system learn;
From Hippocrate thou hast it not,
Nor Celsus nor Pitcairn.

Suppose we own that milk is good
And say the same of grass;
The one for babes is only food,
The other for an ass.

Doctor! one new prescription try
(A friend's advice forgive):
Eat grass, reduce thyself, and die;
Thy patients then may live.

To this attack Dr. Cheyne made the following spirited *riposte*:—

Dr. Cheyne to Dr. Winter.

My system, doctor, is my own,
No tutor I pretend;
My blunders hurt myself alone,
But yours your dearest friend.

Were you to milk and straw confined,
Thrice happy might you be;
Perhaps you might regain your mind,
And from your wit get free.

I can't your kind prescription try,
But heartily forgive;
'Tis natural you should bid me die,
That you yourself may live.

The verses are far neater than is usual in this kind of controversy.—ED. L.

THE PRUDENTIAL ASSURANCE CO., LIMITED.

THE report for 1911 has just been issued. The total number of policies in force in both the ordinary and industrial branches, taken together, numbered at Dec. 31st, 1911, 19,943,441, as against 19,724,323 at Dec. 31st, 1910, an increase of 219,118 policies during the year. In the previous financial year there had been an increase of 466,290 policies during the year. The premiums for 1911 amounted to £12,443,676, as against £12,232,438 for 1910, an increase of £211,238. In the previous year there had been an increase of £350,561. The assets of the company for 1911 amounted to £81,239,682, as compared with £77,529,226 for 1910, an increase of £3,710,456. In the previous year there had been an increase of £3,327,525. The directors have continued the policy of writing down certain securities. It is curious to note how constant the number of deaths in the ordinary branch remained in the two years of 1910 and 1911—viz., 8465 as compared with 8471. The directors announce an increase in the rate of bonus of both branches, and they regret the deaths of two of their colleagues during the year—viz., Mr. John Whately Simmonds and Sir Henry Harben, president of the company. The vacancy in the directorate caused by the death of Mr. Simmonds has been filled by the appointment of Surgeon-Lieutenant-Colonel Horatio Robert Odo Cross, a qualified shareholder, and his election will be submitted to the shareholders for confirmation. Mr. Frederick Schooling has, after 45 years' service with the company, retired from the office of joint manager and actuary, and has been appointed to a seat on the board.

M. and E. S. P.—Electrolysis is certainly the only permanent method of removing hairs. There are various preparations which temporarily remove superfluous hair, but some of them may irritate the skin in so doing, and the hair will certainly return. We believe many who are afflicted in this way now shave periodically and are quite satisfied, defying the old idea that shaving greatly increases the growth. It is improbable that any external remedy will be found capable of removing hairs permanently; and any internal remedy would probably remove the hair of the head as well. This subject was dealt with in an article in THE LANCET of April 11th, 1908.

ERRATUM.—In the report of the Far Eastern Association of Tropical Medicine in THE LANCET of March 9th an error occurs in the statement (p. 674) of Messrs. Burroughs and Wellcome's exhibits. The words "and soamin" were omitted. It is not "epinine" (which is a synthetic substance allied in properties and chemical formula to the suprarenal active principle) but "soamin" that is used for syphilis and trypanosomiasis.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March, April, and May:—

March 23rd-April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
,, (London).—First Congress of Pure Food and Health Society of Great Britain.
,, 1st-7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
,, 8th-13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
,, 8th-15th (Johannesburg).—Thirteenth South African Medical Congress.
,, 9th-11th (Paris).—Congress of Physiotherapy for French-speaking Physicians.
,, 9th (Berlin).—Eleventh Congress of the German Society for Orthopædic Surgery.
,, 9th-13th (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
,, 10th-13th (Berlin).—Forty-first Congress of the German Surgical Society.
,, 14th (Berlin).—Eighth Congress of the German Röntgen Society.
,, 14th-20th (Rome).—Seventh International Congress on Tuberculosis.
,, 15th-18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
,, 21st-24th (Munich).—Twenty-sixth Meeting of the Anatomical Society.
,, (London, Olympia).—Ideal Homes Exhibition.
May 7th-17th (Washington).—Ninth International Red Cross Conference.
,, 13th (London, Guildhall).—Conference on Diet in Schools.
,, 23rd (opens) (Philadelphia).—Twelfth International Congress on Navigation.
,, 23rd-25th (Hanover).—Nineteenth Meeting of the Union of German Laryngologists.
,, 25th-27th (Paris).—International Musical Festival.
,, 26th-28th (Paris).—National Conference the "Gouttes de Lait."
Whitsuntide (Portrush).—British Esperanto Congress
May 27th-June 1st (London).—Eighteenth International Congress of Americanists.
,, 29th-31st (Berlin).—Fifteenth Session of the German Society for Gynæcology.
,, (London).—International Horticultural Exhibition.
May to October (London, Earl's Court).—Shakespeare's England.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, March 13th, 1912.

Date.	Barometer reduced to Sea Level and 32° F.	Direction of Wind.	Rain fall.	Solar Radio in Vacuo.	Maximum Temp. Shade.	Min. Temp.	Wet Bulb.	Dry Bulb.	Remarks.

The following journals, magazines, &c., have been received:—
Journal of Genetics, Child, Annali di Medicina Navale e Coloniale, American Journal of Medical Sciences, Medico-legal Journal (New York), Bulletins et Mémoires de la Société de Radiologie Médicale de Paris, Yale Medical Journal, Monthly Cyclopedia, Pharmaceutical Journal, Dublin Journal of Medical Science, Æsculape, Journal of State Medicine, La Clinique Ophtalmologique, London Hospital Gazette, Tuberculosis, Biometrika, &c.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Lord Rayleigh, O.M.: On the Self-induction of Electric Currents in a Thin Anchor-ring.—Hon. R. J. Strutt: The After-luminosity of Electric Discharge in Hydrogen Observed by Hertz.—Prof. J. H. Poynting: On the Changes in the Dimensions of a Steel Wire when Twisted, and on the Pressure of Distortional Waves in Steel.—Mr. H. S Patterson, Mr. R. S. Cripps, and Mr. R. Whytlaw-Gray: The Critical Constants and Orthobaric Densities of Xenon (communicated by Sir William Ramsay, K.C.B.).—Mr. W. A. Harwood and Mr. J. E. Petavel: Experimental Work on a New Standard of Light.—Mr. J. A. Crowther: On the Distribution of the Scattered Röntgen Radiation (communicated by Prof. Sir J. J. Thomson).—Mr. E. A. Owen: The Passage of Homogeneous Röntgen Rays through Gases (communicated by Prof. Sir J. J. Thomson).—Mr. J. C. Chapman: Fluorescent Röntgen Radiation from Elements of High Atomic Weight (communicated by Prof. Sir J. J. Thomson).—Mr. J. A. Gray: The Nature of the γ Rays excited by β Rays (communicated by Prof. E. Rutherford).

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—H. Charles Cameron, H. H. Dale): at 4.30 P.M.

Papers:

Sir Lauder Brunton, Bt., F.R.S.: Ludwig's and Other Theories of the Secretion of Urine and the Action of Diuretics.

Dr. J. A. Shaw-Mackenzie: Certain Reactions of the Blood in Carcinoma (and Other Conditions) with Suggestions on Treatment.

PATHOLOGICAL SECTION (Hon. Secretaries—J. C. G. Ledingham, A. E. Boycott): at 8.30 P.M.

Annual General Meeting.

Communications:

Dr. C. Russ: An Improved Method for Opsonic Estimations (with demonstration).

Dr. H. Warren Crowe: The Incidence of Streptococci in Urine.

Dr. H. C. Ross: The Mitotic Figures Induced in Lymphocytes by Auxetics (with demonstration).

Dr. W. Nicoll: The Blood-volume of Dogs Infected with the Hook-worm (Anchylostoma Caninum).

Dr. A. E. Boycott and Dr. C. Price-Jones: Experimental Trypanosome Anæmia.

Dr. A. E. Boycott and Dr J. H. Ryffel: The Action of Diuretics in Experimental Nephritis.

Dr. H. R. Dean: A Case of Pneumococcal Ulcerative Endocarditis.

WEDNESDAY.

CLINICAL SECTION (Hon. Secretaries: James Galloway, Charles H. Fagge): at 5 P.M.

Special Meeting at the Medical School, University College Hospital, Gower-street, W.C.

Professor Einthoven (Leyden): Observations of the Movements of the Heart by Means of Electro cardiograms.

Miss Florence Buchanan: Experimental Observations on this Subject.

Dr. James Mackenzie, Dr. Thomas Lewis, and others will Discuss the Clinical Use of this Method.

Those desirous of joining in the discussion are requested to communicate with the Hon. Secretaries of the Section.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—J. H. Sequeira, Wilfred Fox), at 11, Chandos-street, W.: at 5 P.M.

Demonstration of Cases:

Dr. Bunch: Congenital Xanthoma.

Dr. Pernet: Xantho-erythrodermia Perstans (private case).

Dr. Whitfield: (1) Section of Skin of Kitten showing Ringworm Fungus; (2) Culture from Hair of Child Infected by the Kitten.

Dr. Sequeira: (1) Case for Diagnosis; (2) Nævus Vascularis. And other Cases.

NEUROLOGICAL SECTION (Hon. Secretaries—Wilfred Harris, T. Grainger Stewart): at 8.30 P.M.

Clinical Meeting at the National Hospital, Queen-square, W.C.

Cases

Will be shown by Dr. 'Ormerod, Dr. Tooth, Dr. James Taylor, Dr. Risien Russell, Dr. Batten, Dr. Donald Hall, Dr. Turney, Dr. Prentice, and others.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—T. R. Whipham, H. S. Clogg, Percy G. Lewis), at 11, Chandos-street, W.: at 4.30 P.M.

Cases:

Dr. J. L. Bunch: Leucodermia, Melanodermia, and Premature Canities. And other Cases.

Paper:

Dr. A. F. Hertz: Constipation in Childhood, with epidiascope demonstration.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

Paper:

Dr. Miles B. Arnold: The Relation of Housing to Hospital Isolation and to "Return Cases" of Scarlet Fever.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Dr. S. Melville: State Regulation of Vice.

ROYAL METEOROLOGICAL SOCIETY, Institution of Civil Engineers, Great George-street, Westminster, S.W.

WEDNESDAY.—7.30 P.M., Prof. O. Pettersson: The Connexion between Hydrographical and Meteorological Phenomena (illustrated by lantern slides).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Prof. J. W. H. Eyre: The Pathology and Diagnosis of Tuberculosis of the Conjunctiva.

WEDNESDAY.—5 P.M., Dr. L. G. Parsons: The Mechanism and Treatment of Shock.

FRIDAY.—5 P.M., Mr. H. T. Gray: The Mechanism and Treatment of Shock.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. S. E. Dore: Clinique (Skin). 5.15 P.M., Lecture:—Mr. P. J. Freyer: Stone in the Bladder—its Modern Treatment.

TUESDAY.—4 P.M., Dr. A. Jex-Blake: Clinique (Medical). 5.15 P.M., Lecture:—Dr. N. Raw: Tuberculosis of the Genito-urinary Tract and its Treatment.

WEDNESDAY.—4 P.M., Mr. G. Taylor: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. A. Lane: Chronic Intestinal Stasis.

THURSDAY.—4 P.M., Sir A. Pearce Gould, K.C.V.O.: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. R. M. Leslie: Enteroptosis and its Treatment.

FRIDAY.—4 P.M., Mr. G. J. Jenkins: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture VI.)

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: Yellow Fever.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

TUESDAY.—Clinic; 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Mr. H. W. Carson: The Treatment of Surgical Disorders of Digestion.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Dr. A. J. Whiting: The Recognition and Significance of Various Forms of Irregularity of the Pulse.

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical, Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture: Mr. R. Carling: After-treatment of Abdominal Cases.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Prof. Hewlett: Ultra-microscopic Causes of Disease.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY.—4 P.M., Lecture:—Dr. Poynton: Appendicitis in Childhood.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.
TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Buzzard: Myasthenia Gravis
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Buzzard: Cases.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.
TUESDAY.—6 P.M., Dr. W. Griffith: Diseases of the Hair.

UNIVERSITY OF LONDON (UNIVERSITY COLLEGE), The Francis Galton Laboratory for National Eugenics.
TUESDAY.—8.30 P.M., Prof. K. Pearson: Social Problems, their Treatment, Past, Present, and Future. (Lecture VIII.)

LISTER INSTITUTE OF PREVENTIVE MEDICINE, Lecture Theatre of the Lister Institute, Chelsea Bridge-road, S.W.
TUESDAY.—5 P.M., Dr. W. Nicoll: Modern Aspects of Helminthology—General Bionomical Considerations, Nomenclature, Methods of Classification. (Lecture I.)
FRIDAY.—5 P.M., Dr. W. Nicoll: Modern Aspects of Helminthology—General Morphology and Biology of Trematodes and Cestodes. (Lecture II.)

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.
SATURDAY.—3 P.M., Prof. Sir J. J. Thomson: Molecular Physics. (Lecture V.)

ANCOATS HOSPITAL, Manchester.
THURSDAY.—4.15 P.M., Dr. E. B. Leech: Dropsy. (Post-Graduate Clinic.)

SALFORD ROYAL HOSPITAL.
THURSDAY.—4.30 P.M., Dr. F. E. Tylecote: "606." (Post-Graduate Course).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (20th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY 21st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (23rd).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD. THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Sir Clifford Allbutt, K.C.B., Cambridge; Association of Certified Dispensers, Lond., Hon. Secretary of; Mr. Hubert Armstrong, Liverpool; Anglo-American Pharmaceutical Co., Lond.; Messrs. Arnold and Sons, Lond.; Messrs. Adlard and Son, Lond.; Army and Navy Male Nurses' Co-operation, Lond., Secretary of; Dr. H. J. Alford, Taunton; Mr. R. J. Albery, Lond.

B.—Dr. J. Beard, Edinburgh; Mr. A. C. Butler-Smythe, Lond.; Dr. H. N. Barniville, Dublin; British Medical Association, Queensland Branch, Brisbane, Secretary of; Barry Urban District Council, Clerk to the; Mr. A. Bishop, Lond.; Mr. W. Girling Ball, Lond.; Messrs. W. H. The Milroy Lectures

ON

PARATYPHOID FEVER AND MEAT POISONING.

Delivered before the Royal College of Physicians of London

BY F. A. BAINBRIDGE, M.A., M.D. CANTAB., F.R.C.P. LOND., D.P.H.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF DURHAM.

LECTURE II.[1]

Delivered on March 5th.

PARATYPHOID (B) FEVER.

MR. PRESIDENT AND GENTLEMEN,—Comparatively few cases of illness caused by this organism have been recorded in England, although it has been calculated by Boycott that each year in London nearly a hundred cases of clinically enteric fever might be expected to be paratyphoid (B) fever. Several large epidemics and many isolated cases have been described in Germany, and the disease also appears to be prevalent in America and in France.

A small epidemic of 14 cases in Malta has recently been described by Babington; in seven of them the diagnosis was established by blood cultures. It is doubtful whether it occurs, and in any case it seems to be rare, in India and also in South Africa. It is difficult to form an opinion as to the actual prevalence of paratyphoid fever as compared with enteric fever; but the observations of Boycott indicate that in England about 3 per cent. of the cases which run the clinical course of enteric fever are really paratyphoid fever.

From the observations of Klinger, Fischer, and others in Germany, it would appear that the proportion of paratyphoid cases as compared with enteric fever cases is from 8 to 10 per cent.; and a statement by Wells (quoted by Boycott) indicates that about 10 per cent. of the enteric cases occurring in Chicago are really paratyphoid (B) fever. Practically nothing is known as to its seasonal prevalence. Of 10 cases recorded in England 1 occurred in January, 1 in March, 1 in July, 3 in August, 1 in September, and 3 in November. In a recent outbreak of 14 cases in Malta 12 were admitted to hospital in August and September.

DISTRIBUTION OF B. PARATYPHOSUS (B).

The bacillus is very rarely found in man except in patients suffering from paratyphoid (B) fever or in persons who have recently had an attack of paratyphoid (B) fever and are acute or chronic carriers. Savage, for example, examined the stools of a large number of healthy men and of typhoid patients without finding this organism. Bainbridge and O'Brien also carefully searched for it in the excreta of some 300 convalescent enteric cases without finding it on a single occasion. Indeed, this bacillus has practically never been found in England except in cases of illness clinically indistinguishable from enteric fever. English writers consider, therefore, that it occurs only in persons suffering from paratyphoid (B) fever (that is, an illness resembling enteric fever) or in those who have become carriers as a sequel of such an illness.

This view has been challenged by Conradi and by Hübener, who hold that the isolation of B. paratyphosus (B) from the blood or stools of a human being does not in the least indicate (in the absence of other evidence) that he has, or has had, paratyphoid fever. Their opinion is based upon observations as to the distribution of this bacillus in nature. Conradi found organisms described as "paratyphoid" bacilli in 29 out of 250 typhoid convalescents, in patients suffering from tuberculosis, and in healthy people.

Prigge and Sachs-Müke, who examined the stools of 5252 individuals, found "paratyphoid" bacilli in 60 cases apart from those actually suffering from paratyphoid fever. Similar bacilli have been obtained also by Hübener and others from sausages, meat, milk, and water; and Conradi noticed that food containing these bacilli could be consumed by human beings without ill-effect. They are disposed, therefore, to regard "paratyphoid" bacilli as harmless saprophytes widely distributed in man; but Conradi finds it difficult to account for their occasional lapses into virulence. These observations have been subjected to severe criticism.

In the first place, none of the bacilli appear to have been examined by either the absorption method or the complement deviation method, and there is no conclusive evidence that the organisms isolated by these observers were really B. paratyphosus (B). In some cases it is certain that they were not B. paratyphosus (B), since several strains described by them as "paratyphoid" bacilli when examined by the absorption method proved to be B. suipestifer.

Secondly, the evidence that these so-called "paratyphoid" bacilli even belong to the Salmonella group at all is at times incomplete. Some German writers apparently do not recognise that the human alimentary canal frequently contains bacilli which superficially resemble those of the Salmonella group, but which can be distinguished from them by adequate cultural tests and which are not agglutinated by paratyphoid (A) or (B), suipestifer or enteritidis (Gaertner) sera.

The existence of such organisms has been clearly demonstrated both by Morgan, by Savage, and by Bainbridge and O'Brien. In the course of his investigation into the bacteriology of infantile summer diarrhœa Morgan several times isolated bacilli which in their cultural characters differed from the Salmonella group only in one or two particulars. Some fermented cane sugar or salicin, others failed to ferment dulcite, and others formed indol. Similar organisms have been obtained by Savage and by Bainbridge and O'Brien, who further showed that these bacilli were not agglutinated by the sera of animals inoculated with B. paratyphosus (B), B. suipestifer, or B. enteritidis (Gaertner). In a subsequent paper Savage found that bacilli of this type, which he described as "pseudo-Gaertner" organisms, occur with considerable frequency in food of various kinds, especially sausages. These observations indicate the care which must be exercised in identifying any given organism as B. paratyphosus (B).

It is also noteworthy that the frequent occurrence of "paratyphoid" bacilli either in man or in food is apparently limited to one or two districts, more especially to the south-west of Germany; in other parts of Germany they are rarely found. Apart from these criticisms the observations of other writers go to prove that in Germany B. paratyphosus (B) is not widely distributed either in man or in food. This was the conclusion reached by Aumann as the result of a large number of observations on the occurrence of the Salmonella group in food and in the blood and excreta of man and of animals. His results are completely in accordance with those of Müller and others who examined the organs of healthy domestic animals shortly after they were slaughtered. The occurrence of organisms of the Salmonella group was infrequent and was almost invariably associated with outbreaks of disease in man.

The balance of evidence, therefore, is against the view put forward by Conradi and by Hübener. Fully identified and undoubted strains of B. paratyphosus (B) have practically never been isolated either from food or from the lower animals. Its distribution is limited to man, and its habitat is the alimentary canal (including the gall-bladder) of persons suffering from paratyphoid fever or of those who have become carriers after an attack of this disease.

CLINICAL FEATURES.

The clinical description already given of paratyphoid (A) fever is equally applicable to the disease caused by B. paratyphosus (B), as is evident from the descriptions given by Savage, Rolly, Gwyn, and others. Perforation, however, has not been observed, nor is there any record of the occurrence of forms of rash other than rose spots. Fatal hæmorrhage occasionally happens and relapses are not infrequent. Inflammation of the gall-bladder and periosteal abscesses have been met with as sequelæ. In the recent outbreak in Malta ten cases were very mild and four were clinically indistinguishable from enteric fever; one of the latter died. The duration of pyrexia varied from 4 to 30 days, the average being 17 days. Epistaxis occurred and rose spots were present in several cases; severe headache was a frequent and prominent symptom.

As a rule the illness is described as being clinically indistinguishable from enteric fever. Occasionally, however, the onset of the symptoms is more acute and the illness is

[1] Lecture I. was published in THE LANCET of March 16th, p. 705.

ushered in by a rigor or by vomiting, but after a day or two it falls into line with the more typical cases just described and runs a normal course of from two to three weeks. Two other symptoms are sometimes met with which are suggestive of the illness being paratyphoid rather than enteric fever. They are, first, the occurrence of labial herpes; and, secondly, the firmness of the spleen when felt during life as compared with its consistence in enteric fever. In epidemics of paratyphoid (B) fever in Germany these symptoms were noticed in a large proportion of the cases.

One small outbreak of acute gastro-enteritis caused by B. paratyphosus (B) has been recorded by Bainbridge and Dudfield. A similar outbreak described by Schottmüller (1904) and the recent outbreak at Wrexham (1911) were also attributed to B. paratyphosus (B), but the nature of the organism was not established by absorption tests in either of these outbreaks.

POST-MORTEM APPEARANCES.

Fatal cases are infrequent, and the post-mortem records are few in number. In a case described by Babington the Peyer's patches showed no sign of inflammation or ulceration. The large intestine was intensely inflamed throughout its whole length. The mucosa was studded thickly with minute ulcers, varying in size from a pin's head to a sixpence. The ulcers were largest and deepest in the cæcum. In other cases congestion of the lower part of the ileum and ulceration of Peyer's patches have been observed. In one of Savage's cases the lower 18 inches of the ileum were ulcerated; several ulcers presented sloughs, others appeared to be healing. The mesenteric glands were inflamed and the spleen was enlarged. The first four inches of the colon also contained ulcers.

MORTALITY.

In 120 cases recorded by Lenz the mortality was 3 per cent. It is probable that the mortality is low, but the number of cases hitherto met with in this country is too small to justify any very definite opinion on the question, more particularly since—accepting Boycott's calculations—the recorded cases represent only a very small fraction of those which escape recognition.

As regards the influence of previous inoculation against enteric fever on the mortality and severity of subsequent attacks of paratyphoid fever, it may be noted that in the Malta outbreak of paratyphoid (B) fever four cases had been inoculated against enteric fever; three were mild, one was severe. Three had not been inoculated; one was mild, one severe, and one fatal. Details were lacking as to the other seven cases.

DIAGNOSIS.

(1) *Isolation of the Bacillus.*

Paratyphoid (B) fever is a septicæmia, and the bacillus has on many occasions been isolated from the blood or stools during life, or from the internal organs after death.

The isolation of the organism is, indeed, the only certain means of diagnosing paratyphoid (B) fever, since the clinical symptoms are, as a rule, indistinguishable from those of enteric fever.

(2) *Serum Reactions.*

It was hoped at first that the serum reaction (Widal's test) might furnish a trustworthy and ready means of diagnosis; but unfortunately it sometimes yields quite inconclusive results. Its diagnostic value has been carefully examined by Boycott, who reached the conclusion that an accurate determination of the *ultimate* limit of the agglutinating power of the serum for organisms of known agglutinating capacity would, in the majority of cases, give reliable information as to the nature of the infection. Even under these circumstances, however, anomalous results are occasionally obtained, as Boycott pointed out; and when the agglutinating power of the patient's serum for B. typhosus or B. paratyphosus (B) is examined, as is frequently the case, only in two or three dilutions, none of which exceeds 1–100, the serum reaction ceases to have any value as a means of differentiating beween enteric and paratyphoid (B) fever. This is clear both from Boycott's observations and from those of Savage and of Bainbridge. Savage, for example, gives the serum reactions of a patient from whose stools B. paratyphosus (B) was isolated; B. typhosus was agglutinated up to a serum dilution of 1–300, B. paratyphosus (B) in a dilution of 1–500. In a routine examination of the serum for B. typhosus only, in the usual dilutions of 1–20, 1–50, and 1–100, this case would almost certainly have been regarded as one of enteric fever. Undoubtedly many cases which give a positive serum reaction for B. typhosus, when tested in a routine fashion and which are diagnosed as enteric fever, are really paratyphoid fever. In those instances in which the patient's serum agglutinates in high dilution both B. typhosus and B. paratyphosus (B) the absorption method would probably be of assistance in the making of a diagnosis.

Frequently, however, the patient's serum agglutinates B. paratyphosus (B) in very high dilution such as 1–5000 to 1–20000, whereas it fails to agglutinate B. typhosus in higher dilution than 1–100. A diagnosis of paratyphoid (B) fever may then be regarded as almost certain, even though the bacillus is not isolated. There are, however, cases of enteric fever in which the patient's serum agglutinates B. paratyphosus (B) in higher dilution than B. typhosus. Pratt, for example, records a case of enteric fever in which the serum reacted with B. paratyphosus (B) at 1–200 dilution and gave no reaction with B. typhosus at 1–10 dilution; blood cultures gave a pure culture of B. typhosus. An absolute diagnosis of paratyphoid (B) fever in a given case rests, therefore, upon two pieces of evidence—namely, the presence of the clinical symptoms characteristic of enteric fever, and the isolation of B. paratyphosus (B) from the patient. Failing the isolation of the bacillus, a probable diagnosis can often be made from the serum reaction of the patient.

EPIDEMIOLOGY.

Attention was first called to the existence of human paratyphoid (B) carriers by Lenz (1905–06). He recorded 6 cases, one of which was under observation for at least a year. Since then a considerable number of carriers have been met with. Brückner recently examined the excreta of 316 individuals who had had paratyphoid or enteric fever at least a year previously. Three of these were chronic carriers of B. paratyphosus (B), and two of them were excreting the bacilli three years after the original attack of illness. Similar cases have been recorded by Hamilton (5 cases), Mayer (10 cases), Prigge and Sachs-Müke (6 cases), and others. In all I have met with an account of 29 chronic carrier cases. An analysis of these brings out two striking facts. In the first place, 26 of the carriers were women (in one case the sex is not stated); and secondly, seven of them either were suffering from cholecystitis or had gall-stones. Forster and Kayser, indeed, isolated B. paratyphosus (B) from the gall-bladder of a woman post mortem; in this case gall-stones were present. Further, all the cases examined by Prigge and Sachs-Müke gave a positive serum reaction for B. paratyphosus (B). In these respects paratyphoid carriers show a striking resemblance to chronic typhoid carriers, which also predominate in the female sex, and are frequently associated with disease of the gall-bladder.

So far as can be judged from the literature, all these cases were chronic carriers; practically nothing is known as to the occurrence of acute carriers, although there is no reason to suppose that they do not occur. Apparently all the cases yet described have been fæcal carriers, and I can find no record of a urinary carrier of genuine B. paratyphosus (B). Most of them further resemble typhoid carriers in the constancy with which the bacilli are excreted from day to day, and the abundance in which they are found. They differ entirely, therefore, from the cases described by Conradi of the excretion of the "paratyphoid" bacilli; Conradi found that the bacilli were excreted on a single occasion only, and even then in very minute numbers.

The question of the capacity of paratyphoid (B) carriers to cause infection has, so far, received very little attention. Such evidence as we possess is of the same character as that in favour of the infectivity of typhoid carriers. As is well known, the capacity of the typhoid carrier to cause disease has been challenged by several epidemiologists, of whom Hamer is the most prominent. We may summarise, however, the few facts that are known which point to the direct causation of paratyphoid (B) fever by carriers.

1. While investigating an epidemic of enteric fever Wernicke (1907) found by bacteriological examination that 6 per cent. of the cases were paratyphoid (B) fever; the cause of the epidemic was traced to a milk-shop in which resided or worked several typhoid carriers and one paratyphoid (B) carrier. It was believed that the milk infected by these carriers was the cause of the combined outbreak.

2. Within the last year or two Sacquepée and Bellot have

published an account of an epidemic of paratyphoid (B) fever, and have given good reasons for attributing the source of the infection to a carrier. In a corps of 250 soldiers in France, 19 cases of paratyphoid (B) fever occurred in the course of eight days. The duration of the illness was from two to three weeks, and the clinical course was that of mild enteric fever; no deaths occurred. B. paratyphosus (B) was recovered from the fæces or urine of 12 cases, and all the cases gave a positive reaction for this bacillus. An inquiry into the cause of this infection made it clear that the water-supply could be excluded. It was found, however, that a man who cooked the food for these soldiers had suffered from paratyphoid fever a short time before the occurrence of the epidemic. His blood gave a positive reaction for B. paratyphosus (B), and this organism was isolated from his stools. Repeated examinations of his stools were made during some months, always with a positive result, and there can be no doubt that he was a paratyphoid carrier.

Although this scanty evidence does not justify the conclusion that carriers are the only, or even the actual, cause of paratyphoid fever, the carrier hypothesis is the most probable one yet adduced to account for its distribution. Unfortunately, opportunities for testing this hypothesis are infrequent in this country since paratyphoid fever is seldom recognised and is almost always sporadic.

No mode of infection other than by carriers has been demonstrated. Attempts to connect the illness of the patient with water-supplies or with animal diseases or with infection by animals have been unsuccessful. Nor is there any evidence that infection has been conveyed by flies, although B. paratyphosus (B) has been isolated on one occasion from the intestine of a fly (Nicoll).

The assumption that paratyphoid fever is spread by human carrier cases does not involve, of course, an absolutely direct infection. Indirect infection by means of milk has already been mentioned, and in the outbreak described by Sacquepée and Bellot some form of food infected by a carrier apparently caused the illness. Indirect infection of this kind is, of course, well known in the case of enteric fever.

SUMMARY.

It is clear from the preceding description that there is no real distinction between the disease caused by B. paratyphosus (A) and that caused by B. paratyphosus (B). The clinical symptoms and post-mortem appearances are practically identical; and in both cases the disease appears to be spread mainly, if not entirely, by human carriers. Both organisms usually give rise to an illness clinically resembling enteric fever, although very occasionally they set up acute gastro-enteritis. Further, the habitat of both organisms is the human alimentary canal. The only important points of difference between infection by B. paratyphosus (A) and by B. paratyphosus (B) consists in the varying response of the patient as regards the production of agglutinins in his serum. Up to the present most of the carriers of the paratyphoid (A) bacillus which have been recognised have been of the acute variety, whereas the carriers of B. paratyphosus (B) are chronic carriers. This apparent difference probably depends upon the special circumstances under which paratyphoid (A) fever in India has been studied.

We are fully justified, therefore, in describing as paratyphoid fever both the illness caused by B. paratyphosus (A) and also that caused by B. paratyphosus (B). It is desirable, however, at the present time to exclude from this category the cases of acute gastro-enteritis which have been caused by these two organisms on rare occasions.

It is interesting to notice the close analogy between paratyphoid and enteric fever from the clinical and epidemiological point of view. Broadly speaking, they differ only in the higher mortality and greater severity of enteric fever and in the character of the causal organisms.

The preventive treatment of the better known disease consists: first, in the isolation, as far as possible, of recognised carriers, and, secondly, in the prophylactic use of typhoid vaccine. In the case of paratyphoid fever neither of these methods appears to have been employed in Europe. In India definite carriers are isolated, but little if any use has been made of paratyphoid vaccines as a protective measure. The widespread occurrence of this disease in the British Army in India would certainly seem to justify their employment. From a bacteriological point of view there is every reason for supposing that it would be as effective for paratyphoid fever as it has proved to be for enteric fever.

MEAT POISONING.

It has long been recognised that the consumption of unsound or even of apparently sound meat may give rise to disease. In some instances the illness is caused by parasites in the meat (e.g., trichinosis); in others it is due to such organisms as the tubercle bacillus. These sources of infection will not be considered; I propose to deal only with the well-known form of acute gastro-enteritis which follows the consumption of some definite article of food, and is popularly described as meat poisoning. This term is used in these lectures in a wide sense to include outbreaks caused, not only by various forms of meat, but also by fish and by food of *animal* origin, such as cheese and milk. The illness caused by grain is excluded. Apart from the clinical symptoms the characteristic features of an outbreak of meat poisoning are two in number. They are, first, the practically simultaneous onset of symptoms among those who have eaten some given article of food; and, secondly, the limitation of the illness to those who consumed the food. The latter statement requires some qualification, since illness occasionally, though rarely, occurs among those who have not partaken of the infected meat, but have been in close contact with the other patients.

The isolation of B. enteritidis by Gaertner (1888) and of B. aertrycke by De Nobele and by Durham (1898) in outbreaks of meat poisoning directed attention to these organisms as a cause of such outbreaks. If the records are to be trusted a large majority of the cases of meat poisoning is caused by the consumption of meat infected with one or other of these bacilli; this is undoubtedly true of most of the recent outbreaks which have been adequately investigated. There is, however, a certain number of cases in which these organisms are not present and which may be due to ptomaines.

Ptomaine Poisoning.

It must be remembered that the term ptomaine poisoning is used in two senses. Sometimes it is regarded as being synonymous with meat poisoning; this, however, is a complete misuse of the term and conveys an entirely erroneous impression of the causation of meat poisoning. The term was originally applied by Vaughan and others to poisoning by definite chemical substances formed in meat which they called ptomaines. At that time the infection of meat by B. enteritidis (Gaertner) or by B. suipestifer was not recognised. They long believed that as a result either of autolytic changes in meat or of putrefaction of bacterial origin poisonous substances were formed which gave rise to the clinical symptoms of meat poisoning. The illness was often preceded by a very brief latent period (half to three hours). These substances were called ptomaines. The poisonous bodies formed during putrefaction were regarded not as specific toxins but as products of protein disintegration, and some of them (e.g., putrescin and cadaverin) were isolated in the laboratory.

I have been unable, however, to find any instance in which the presence of such substances has been demonstrated in meat which has caused disease. The statement, for example, that poisoning by cheese is caused by the presence of tyrotoxicon in cheese is based on inadequate evidence; even in the original outbreak described by Vaughan the possibility of bacterial infection of the patients was not excluded. Very little is known, moreover, either as to the nature of the toxic products of protein disintegration or as to the stage of disintegration at which they are formed, and the difficulties of investigation are increased by the fact that in come cases at least the ordinary laboratory animals are much less susceptible than man to poisoning by these products. Definite proof that a given case of meat poisoning is caused by ptomaines is therefore very difficult to obtain, and the diagnosis rests mainly on the absence of other possible causes of the illness; it is desirable always to exclude the possibility of specific bacterial infection of the food before attributing meat poisoning to ptomaines.

There is, however, a rather important group of cases caused by the consumption of tinned meat which may possibly be regarded as coming into this category. The principal symptoms of the disease thus caused are diarrhœa and vomiting; the disease is of short duration, not usually lasting more than two or three days and sometimes only a

few hours. I have recently had the opportunity of investigating several outbreaks of illness, one caused by tinned salmon, the others by corned beef. An interesting point which was noticed in all these cases was the rapid onset of symptoms after the consumption of the food, the interval being rarely more than five or six hours, and in two cases less than an hour. It was also observed that the meat taken from the freshly opened tin appeared to be more harmful than when the meat had been exposed to the air for some hours. The beef and salmon which had caused the illness were subjected to careful bacteriological examination. The food looked perfectly good and showed no signs of decomposition. A portion of the different samples was administered by the mouth to cats, mice, and guinea-pigs. The corned beef caused no ill effects, although a cat which was fed on tinned salmon had some diarrhœa. Saline extracts made from the various samples of corned beef were injected into mice and guinea-pigs, but the animals remained perfectly well. These foods were also examined for the presence both of aerobic and of anaerobic organisms, but except for a few cocci probably derived from the air they remained sterile. Finally, one sample of tinned beef was analysed chemically for the presence of poisonous metals such as lead, tin, or arsenic; the results were again negative. The negative bacteriological evidence, the very brief latent period and the short duration of the illness render it probable that these outbreaks were due, not to infection, but to a chemical poison, although the actual cause of the illness was not ascertained.

There are, however, cases of poisoning by tinned meat in which organisms are isolated from the meat. In an outbreak at Carlisle staphylococci were obtained, but their relation to the illness caused by the meat remained doubtful, since they were not pathogenic for animals. In another outbreak following the consumption of tinned mutton B. suipestifer was isolated both from the meat and from the spleen and alimentary canal of the patient who died. This case was not due to ptomaines, and it is interesting to note that in contrast with those just considered the latent period of the illness was from 24–36 hours.[2]

INFECTION.

The consumption of meat infected with B. enteritidis (Gaertner) or B. suipestifer gives rise to most cases of meat poisoning. Two other causes have been described—namely, infection of the meat with other organisms, and intoxication by the toxins of B. enteritidis (Gaertner) or B. suipestifer. It can hardly be doubted that purulent meat, or meat infected with pyogenic organisms, may give rise to illness if consumed; and pyogenic organisms of one kind or another have occasionally been found in meat which has caused illness; but cases of this kind do not appear to be either numerous or important.

INTOXICATION.

As is well known, B. enteritidis (Gaertner) and B. suipestifer produce toxins which are extremely resistant to heat, but it is not always clearly understood that they are entirely intrabacillary (endotoxins) and that no extrabacillary toxin is formed so far as we know. The amount of toxin present in meat, therefore, must vary directly with the degree of bacterial multiplication which has previously taken place.

There is no doubt that many, perhaps most, cases of infection with these organisms are accompanied by some degree of intoxication, but a simple intoxication, apart from infection, appears to be of rare occurrence, or at least seldom to have been demonstrated. One reason for its infrequency may be that, as is clearly proved (Rimpau, McWeeney), the ordinary process of cooking often fails to destroy these bacilli in the deeper portions of the meat. Further, intoxication by these toxins would be difficult to demonstrate since we have no adequate means of detecting their presence. Possibly the examination of the patient's serum a few days after the illness might be of assistance. We know, of course, that agglutinins are formed in response to the injection of killed bacilli; and in the present case the toxin practically represents the bodies of the dead bacilli. One might expect, therefore, that after an intoxication of this kind the patient's serum would agglutinate B. enteritidis (Gaertner) or B. suipestifer. This test would only be of value provided that a definite infection by living bacilli had been excluded. So far as I am aware, this method has not hitherto been employed.

Nor does there seem to be, at present, any clear means of distinguishing between intoxication and ptomaine poisoning. The only ground, indeed, for regarding a given case of meat poisoning as due either to intoxication by the toxins of B. suipestifer or B. enteritidis (Gaertner) or to ptomaines is the failure to obtain definite bacteriological evidence that the meat was infected. Even the onset of symptoms within two to three hours after the consumption of the meat does not furnish conclusive evidence that the cause of the illness was an intoxication or was due to ptomaines. In the Chesterfield outbreak, which was clearly proved to be caused by pies infected with B. suipestifer, some of the patients became ill two and a quarter hours after eating the pies.

It thus appears that, in a certain number of cases of meat poisoning, infection by organisms cannot be demonstrated. In many of these cases the latent period is extremely short, the illness is of brief duration, and the meat is not pathogenic for laboratory animals. These outbreaks are sometimes attributed to poisoning by ptomaines or by the toxins of specific organisms such as B. enteritidis (Gaertner), although conclusive proof as to their mode of causation is lacking.

MEAT POISONING CAUSED BY B. SUIPESTIFER, OR B. ENTERITIDIS (GAERTNER).

We may now consider the outbreaks of meat poisoning which are associated with the presence of B. suipestifer or of Gaertner's bacillus. In some of these cases the bacillus was isolated both from the patients and from the food which caused the outbreak; in others it was obtained either from the food or from the patients.

Prevalence.

In Germany outbreaks of this kind are of frequent occurrence, and during the years 1898–1908 at least 261 have been recorded. Although Germany is pre-eminently the home of meat poisoning, outbreaks occur from time to time in most European countries and in America. They appear to be more frequent in countries in which much uncooked meat is eaten; and there is reason to suppose that the extensive consumption of uncooked meat in Germany is in a large measure responsible for the prevalence of this disease in that country. In the British Isles the more important recent outbreaks have been those at Hatton, Murrow, Chesterfield, St. Ann's, Tollesbury, and Limerick.

It might be anticipated on general grounds that bacterial changes in meat would occur more readily in summer, and that cases of meat poisoning would be more numerous at this time of year; and such is actually the case. Hübener found that of 36 cases 16 occurred during June, July, and August, and 30 between May and October. In another series of 27 epidemics (Sacquepée) 11 occurred in June, July, and August, and 20 between June and November. B. suipestifer is found rather more often than Gaertner's bacillus in these outbreaks; in 72 outbreaks the former was found 40 times and the latter on 32 occasions.

Clinical Characters.

A study of the more extensive and fully described outbreaks reveals a remarkable uniformity in the clinical symptoms which are observed. After the consumption of the contaminated food the onset of symptoms is preceded by a latent period varying from 6 to 24 hours, occasionally as long as from 48 to 72 hours; in any given outbreak the latent period is usually of approximately the same length for all the patients. Even in the same outbreak, however, it may vary considerably according to the time during which the food is kept before being eaten. Thus in the recent outbreak at Chesterfield, which was caused by pork pies, the average latent period before the onset of symptoms among those who ate the pies, two days after they had been cooked, was 22 hours; when the pies were four days old the latent period was 20 hours; when they were six days old it was 14 hours; and on the seventh day it was 2¼ hours.

The illness often begins with a severe headache or with a rigor speedily followed by acute gastro-intestinal disturbance—nausea, diarrhœa, vomiting, abdominal pain. In the more severe cases restlessness, extreme thirst, and nervous symptoms, such as cramp, become prominent, and death may

[2] Illness following the consumption of meat taken from resoldered leaky or "blown" tins has been left out of consideration; in all the instances discussed above the tins appear to have been sound and air-tight.

be preceded by coma. Fever is usually present and the temperature may reach 102° to 103°. As a rule the temperature falls to normal in from two to five days, and the vomiting and diarrhœa cease. The total duration of the illness rarely exceeds a week, but convalescence is often delayed by general muscular weakness or by attacks of circulatory impairment. Occasionally cases occur in which the temperature is raised for two to three weeks. All degrees of severity are met with, from fulminating cases, which may die within 24 hours, down to those of slight diarrhœa or malaise insufficient to keep the patient from work; some of those who eat the meat may remain unaffected. The clinical symptoms do not differ from those caused by some irritant poisons, and in sporadic cases the relation of the symptoms to the consumption of unsound meat may be difficult to establish. In large outbreaks, however, the practically simultaneous occurrence of all the cases, and the comparative infrequency of secondarily infected patients, can usually be readily correlated with the consumption of some particular article of food.

Post-mortem Appearances.

In the few cases recorded the post-mortem appearances have been very much the same. The mucous membrane of the stomach and intestines is swollen, and often intensely congested; the Peyer's patches are not specially involved. Minute ulcers are not infrequently present, but show no tendency to occur in any particular region of the alimentary canal. Fatty change may be visible in the liver, which then shows numerous small yellowish areas. The other organs present no noticeable alteration.

Mortality.

The average mortality is from 1·5 to 2 per cent., that in outbreaks caused by Gaertner's bacillus being higher than in those caused by B. suipestifer. In an outbreak at Breslau due to B. suipestifer there were 80 cases and no deaths, whereas in the Limerick outbreak caused by B. enteritidis (Gaertner) there were 73 cases, 9 of which were fatal. Taking a large number of epidemics the average death-rate in those associated with B. suipestifer was just over 1 per cent. as compared with 3·5 per cent. in those caused by Gaertner's bacillus. A possible explanation of this difference will be discussed later.

Diagnosis.

During the course of the illness the bacilli can often be isolated in large numbers from the stools of the patients, but they generally disappear in a week or ten days after the onset of the illness. Blood cultures are not often made, but in many cases the bacilli probably enter the circulation; post mortem the bacilli can be isolated from the heart-blood, spleen, and other viscera. A positive serum reaction is usually present six to eight days after the onset of the illness, and may become very marked during the second or third week.

The same organism is not infrequently isolated both from the patients and from the food which caused the illness. Its isolation from both these sources suffices to establish the diagnosis; and the presence of agglutinins in the patient's serum furnishes additional proof of the existence and nature of the infection. Indeed, a diagnosis may be made with fair probability on the serum reactions of the patient alone, since it is extremely rare to find a positive serum reaction for B. suipestifer or B. enteritidis (Gaertner) in healthy individuals.

The inoculation of animals with emulsions of the food or the feeding of animals with the meat is undesirable as a means of isolating these organisms in cases of meat poisoning, since either of them may be normally present in healthy laboratory animals, such as rats, mice, and guinea-pigs.

The foregoing description holds good for infection either by B. suipestifer or by B. enteritidis (Gaertner). The two organisms, however, have a different distribution, and it will be convenient to consider separately their relation to meat poisoning.

AN OPHTHALMOLOGIST'S GIFT TO HIS OLD CLINIC.—Dr. Joseph Schneider, who was formerly assistant in the Würzburg Ophthalmic Clinic, but has long been resident in Milwaukie, U.S.A., has sent 100,000 marks (£5000) to his old clinic for the free treatment of poor people.

ABSTRACT OF

Sir Hunterian Lectures

ON

CERTAIN PHASES IN THE EVOLUTION OF MAN.

Delivered before the Royal College of Surgeons

BY ARTHUR KEITH, LL.D., M.D. ABERD., F.R.C.S. ENG.,

CONSERVATOR OF THE COLLEGE MUSEUM.

THE DISCOVERY OF THE IPSWICH SKELETON.

THROUGH the courtesy of Mr. J. Reid Moir, of Ipswich, Professor Keith stated that he had had the opportunity of examining, at the College, the remains of a human skeleton which had recently been discovered beneath a stratum of undisturbed chalky boulder clay in a sand-pit at Ipswich. He regarded the skeleton as of very great antiquity. Compared with other ancient human remains which have been found in England, he believed that the only one which stands in point of age is the Galley Hill man whose remains were found in a 100-foot terrace of the Thames Valley. The 100-foot terrace rests on the boulder clay, therefore the boulder clay formation is older than the 100-foot terrace, and consequently the Ipswich skeleton belongs to a much earlier date than the Galley Hill man. The flint implements which have been found in the boulder clay and in the mid-glacial sands which lie beneath the boulder clay, and in which the Ipswich skeleton was partly imbedded, are of a more primitive type. The lecturer was of opinion that there could be no question of burial, for the various horizontal lines and markings were continued across in the strata above the bones, showing that they were in the condition in which they had been originally laid down. As the bones were too fragile to be removed the overlying strata were cut away and the layer containing the bones was dug out in blocks and forwarded to the College museum. The skeleton is that of a man whose height is estimated at 5 ft. 10 in. With the exception of the Cromagnon races all palæolithic men yet known are of a low stature. Though the discovery at Galley Hill showed that the modern type of man was very ancient, Professor Keith said that he was not prepared to find beneath the chalky boulder a man of the modern type. Yet in teeth, in skull-form, and in the leading features of the skeleton, the Ipswich man does not differ in build of body from the men of to-day. He expressed the opinion that perhaps too much attention had been directed to the skull. It is very probable that the tibia, being so closely associated with the human manner of walking, will serve to distinguish various stages in man's evolution. The tibia of Neanderthal man recalls the same bone in the gorilla, but it is differentiated from the simian form by possessing a definitely marked anterior border or shin. In other palæolithic races and in all other human races the shin of the tibia is prominent and sharp. The shin of the Ipswich tibia is quite peculiar and unlike any form yet seen. In place of a sharp shin there is a flat surface. It does not represent a pathological condition, but is evidently due to a peculiarity in the gait of the individual.

NEANDERTHAL MAN AND MODERN RACES.

Some modern anthropologists were of opinion that Neanderthal man had gradually shed his simian features and become transformed into the modern type. On the other hand, others believed that such a transformation was impossible, and that Neanderthal man became extinct, leaving no progeny. The lecturer confessed that though at one time he had supposed that the transformation of the Neanderthal to the modern type was possible, the evidence which accumulated in recent years had compelled him to abandon this view. The many discoveries of this peculiar race, which had been made abundantly in France during recent years, belonged to a comparatively late phase of the Pleistocene period. Long before that period, not only in England, but also on the continent, men of the modern type existed. In quoting the case of the human mandible, Moulin Quinon, which Boucher de Perthes, the founder of our knowledge of

Palæolithic man, discovered near Abbeville, in the valley of the Somme, in 1863, the lecturer believed that the chief objection to it is that it so nearly approaches the modern type. Yet Boucher de Perthes took it with his own hand from a deep and old stratum which belongs to an age which preceded the Neanderthal period in France. The mandible is of the type we should expect in the race to which the recently discovered Ipswich skeleton belongs. Several of the Pleistocene crania found in France were pre-Neanderthal in date and yet were of the modern type. The most remarkable and best authenticated of all discoveries of man is that made at Castenedolo, near Brescia, Lombardy, by Professor Ragazzoni between 1860 and 1880. In strata belonging to an early Pliocene age and in conditions which showed that these strata had never been disturbed, he found parts of four human bodies, one the almost complete skeleton of a woman. Professor Sergi, who described these remains, found them to be of the modern type.

MAN AND MODERN ANTHROPOIDS.

In discussing ancient man and modern anthropoids Professor Keith was of opinion that, though the latter did not stand in the line of human descent, there could be no question that their ancestral stock did, for the resemblances between man and the African anthropoids were so many and so close that they could be explained only by a common origin. The African anthropoids were related to man only by a distant and very ancient cousinship, yet they undoubtedly represented the common ancestral stock much more closely than man did, and it was therefore possible to obtain by a close study of modern anthropoids some clue to the manner in which evolution worked in the primitive forms of man. Pleistocene man in Europe presented a condition exactly parallel to what was seen to-day among African anthropoids. The great, strong, brutal gorilla exemplified Neanderthal man; the more finely moulded, less brutal, nimble-witted chimpanzee, divided into a number of races, represented the modern forms of man. It was not to be supposed that there was any direct relationship between the human European and African anthropoid counterparts; in the one case both were men, in the other both were anthropoids. In the evolution of man and anthropoids similar physiological or evolutionary processes have been at work. In Neanderthal man the teeth are massive, the muscles of mastication large, the various bony processes of the skull—from which these muscles took their origin—greatly developed, while the skull was widely and strongly hafted to the neck. The gorilla showed similar characters. The various chimpanzees, like modern races of mankind, exhibited a strong tendency towards a reduction in size and development of teeth, with a corresponding lessened growth of the muscles and apparatus for mastication. At birth the skulls of gorillas and chimpanzees were very much alike. The chimpanzee as it grew up stood still at a certain point of brutalisation, while the gorilla pressed on to the ultimate limit. It would, no doubt, be found that at birth the skulls of modern man and Neanderthal man were very similar. Of the various existing anthropoids there could be no doubt that the gorilla showed the greatest assemblage of human characters.

THE GIBBON AND MAN'S EVOLUTION.

The gibbon was the most important of all surviving apes. Those who were familiar with the gibbon as seen in the Zoological Gardens, or who have kept them as pets, valued them for their mental and bodily characters. The student, however, was drawn to them because, structurally, they belonged to a very ancient world, and threw light on a very early stage in man's origin. The gibbon which lived in Europe in Miocene times was now confined to the jungles of further India, Borneo, Java, and Sumatra. There were two very distinct kinds—the large gibbon and the small or ordinary gibbon, spread over a vast jungle or forest country. The structural differences between the siamang and gibbon were similar in degree and in nature to those which separated the gorilla from the chimpanzee. Mankind, during the greater part of the Pleistocene epoch, was separated into two distinct types—the Neanderthal and the modern. When it was remembered that the gibbons, African anthropoids, and Pleistocene man represented three successive stages in the evolution of the highest primates, it was a remarkable fact that there should be in each stage a process at work which led to a separation into two kinds—one a massive and brutal form restricted in numbers and in distribution and divided into numerous varieties or races. The siamang, the gorilla, and Neanderthal man were the representatives of the brutal type, while the gibbon, the chimpanzees, and the modern human types were the representatives of the other. We were apt to think, said Professor Keith, of the upright posture as a human characteristic, but this was not the case. It was true that in man only were the lower extremities adapted for ground progression, but these changes, remarkable as they were, were minor ones compared with the transformation which we saw in the body of the gibbon. The gibbon was essentially an ordinary monkey adapted to the upright posture. There could be no doubt that in all the very ancient primates the axis of the body was carried horizontally; the gibbon was the earliest known form in which the axis of the body was carried upright; in its system we saw the introduction of a structural principle which served as the stepping-stone to a human posture. The period of the evolution of the gibbon dated back to soon after the separation of the fauna of Africa from that of South America, the latter continent being apparently the centre of evolution and of the earliest forms of monkeys.

EXTINCT ANTHROPOIDS.

From an examination of extinct forms of animals closely allied to mankind, the lecturer supported the opinion that the antiquity of man was very much greater than had been hitherto supposed. He attached great importance to dryopithecus, a great anthropoid which lived in the jungles of Europe during the Miocene epoch, and became extinct early in the Pliocene. It was about the size of the chimpanzee, and like that animal in several features, but it differed in certain points from all the existing great anthropoids and showed features which linked it with the small and much more primitive anthropoid—the gibbon. Dryopithecus was widely spread in Europe; the most complete remains have been found in the Middle Miocene formation of the South-West of France. Its teeth occurred in rather later formations in the upper valley of the Rhine and in the valley of the Danube. At least three forms of this great anthropoid had lived in Europe. The molar teeth of this ape had rather a close resemblance to the corresponding human teeth. It was possible that some of the molars attributed to this animal were really human teeth, or of the Miocene stock which gave rise to man. The molar teeth were the only points in which dryopithecus resembled man, and there was no reason to regard this extinct anthropoid more than another as a possible human ancestor. The teeth and jaws of the European gibbon of that long-past or Miocene period differ from those of their modern representatives to about the same degree as the corresponding parts of a modern Englishman differ from those of an aboriginal Australian. To students of human evolution the discovery of the gibbon at the beginning of the Miocene epoch is a matter of great importance, as we know thereby that the upright or vertical posture was already evolved. Professor Keith stated that an account of "the most important and surprising discovery" yet made regarding the early history of the primates was recently published (1910) by Dr. Max Schlosser. In the oldest of the Oligocene formation of the Fayum of Upper Egypt remains of three forms of monkeys were found. Two of these Dr. Schlosser regards as close allies of South American monkeys; the other he regards as an ancestor of the Miocene gibbon of Europe. The discovery had a double importance: it showed in the first place, that the Old World monkeys and anthropoids had, as many formerly believed, a common origin with those of South America; in the second place it showed that the basal anthropoid stock was in process of evolution at the beginning of the Oligocene period.

PRESENT POSITION OF THE THEORY OF HUMAN EVOLUTION.

In reviewing the state of knowledge concerning the evolution of man, Professor Keith was of opinion that all the evidence indicated a very great antiquity for later phases in the evolution of the human body. Mankind as seen in the world to-day—European, Mongolian, Red Indian, and Australian—were most diverse in type. Their evolution from a common stock demanded the elapse of an enormous length of time. In England we find the types of skulls of her most ancient inhabitants repeated in her modern population. With the exception of the Neanderthal type, all the ancient continental forms are still to be found in Europe. From predynastic to modern times the skull of the Egyptian has

changed only in detail. The oldest human crania found in America are of the Red Indian type. We are forced to believe, said the lecturer, that human evolution works slowly, and yet it has effected the extraordinary contrast seen between two such representatives of the modern type as the negro of Africa and the fair-haired native of North Europe. To accomplish such a degree of divergence one must carry the history of modern man at least well within the Pliocene period. Of the survivals of ancient human forms it is very likely the aboriginal Australian is the best living representative of Pliocene man. From such a type one can understand the origin of the negro on the one hand and of the European on the other. As regards the degree of relationships between man and the great anthropoids, the opinion of scientific men had changed very little since Darwin's time. Huxley regarded the structural difference between man and the gorilla as about equal in degree to that which separated the gorilla from ordinary monkeys. The divergence between the gorilla and monkey is undoubtedly the greater. It can be safely said that the brain of the gorilla represents an intermediate stage between the brains of man and of the small anthropoid, the gibbon; the brain of the dog-like monkey represents a still lower or more primitive stage. In 1904 Professor Nuttall confirmed the inferences which anatomists had drawn concerning the relationship of man to anthropoids and monkeys. He established the fact that the blood of the great anthropoids responds to vital tests to a degree almost equal to human blood; the reaction became less when the test was applied to the blood of monkeys. The response in the case of those of the Old World was greater than those of the New, thus bearing out the anatomists' opinion that the Old World monkeys are more recently related to the human stock than those of South America. There was also the evidence of disease. The great anthropoids were susceptible to syphilis—a human disease; the monkeys could be inoculated with difficulty. Anthropoids in captivity were liable to typhoid fever, and they frequently died from that very human disease—appendicitis. There was no evidence that appendicitis occurred when the anthropoids lived in their native habitats, and on their natural diet.

FEEBLE-MINDEDNESS AND THE MEASUREMENT OF THE INTELLIGENCE BY THE METHOD OF BINET AND SIMON.

By W. C. SULLIVAN, M.D. R.U.I.,
MEDICAL OFFICER IN H.M. PRISON SERVICE.

Now that the problem of the feeble-minded is passing from the stage of general and somewhat vague discussion to become a matter for practical and detailed consideration, it will probably be necessary to devote rather more attention than has hitherto been customary to the question, Who are the feeble-minded, and how are they to be recognised? It is a little remarkable that, despite the enormous output of literature dealing with this subject within the last few years, a point of such obvious importance should on the whole have received such very inadequate treatment. It is not, of course, neglected in the numerous text-books, but it cannot be said that the pages which they devote to its consideration take us very far; in most instances, indeed, the writer seems to realise that his success in meeting this difficulty is rather indifferent, for when, after some destructive criticism of the technically phrased definitions of his predecessors, he has propounded an equally defective one himself, he prudently winds up by counselling us to be content with the general indications on this point that are laid down in the Report of the Royal Commission on the Care and Control of the Feeble-minded. That report, it will be remembered, defined the feeble-minded, in terms suggested by the Royal College of Physicians of London, as "persons who may be capable of earning a living under favourable circumstances, but are incapable from mental defect existing from birth or from an early age (*a*) of competing on equal terms with their normal fellows, or (*b*) of managing themselves and their affairs with ordinary prudence."

This definition was admirably suited for the purpose for which it was designed—namely, to indicate the scope of the inquiry referred to the Royal Commission; but it is obvious that it does not provide, and is not intended to provide, what is required for the practical work of diagnosis. It does not furnish the medical examiner with any definite criterion by which he may judge whether the given individual with whom he has to deal is or is not feeble-minded; it does not suggest how an opinion can be formed in advance as to whether the individual will be "unable to compete with his normal fellows" or "to manage his affairs with ordinary prudence," or, if he has already shown his incapacity in these directions, it does not indicate the grounds on which it is to be concluded that the proved failure is due to mental defect. On the other hand, the definition has the very great merit of being founded on strictly empirical data; and until we know a great deal more than we have yet learned about the normal as well as the feeble mind, it is very certain that definitions of this modest character are all that we can usefully attempt. What appears to be needed, therefore, is a development of the empirical test of the Commission in a fuller and more precise form, so as to define feeble-mindedness by reference to an accepted standard of intelligence, and further to furnish a convenient method for applying this standard in practice. I propose in this paper to point out that such a standard and method may be found in the ingenious *échelle métrique de l'intelligence* devised some years ago by M. Binet and M. Simon for estimating the degree of intellectual development in school children. Possibly the scale may need some modifications to fit it for measuring the intelligence of the mentally defective of adult years, and at the time of his lamented death a few months ago the late M. Binet was, in fact, revising it from this point of view; but, as shall I have occasion to remark later on, it is probable that the necessary alterations will be even slighter than M. Binet supposed. The question, meanwhile, it is satisfactory to note, is engaging the attention of M. Binet's able and devoted fellow-worker, Dr. Th. Simon.

In principle the method of M. Binet and M. Simon is very simple. By extensive observations on French school children at different ages, they were able to arrange a great number of mental tests in a series of groups graduated according to their increasing difficulty after such a fashion that each group corresponds to what the average child of a given age can do. The tests in each group are of several kinds, and, though theoretical considerations are deliberately eschewed by the authors, it is evident that the choice of the tests has had in view the different aspects of intellectual activity. This can be seen from a glance at the list of tests:—

3 years.—(i.) Point out nose, eye, mouth; (ii.) repeat a number with two figures; (iii.) enumerate the objects in an engraving; (iv.) tell surname; (v.) repeat a sentence with six syllables.

4 years.—(i.) Tell whether a little boy or a little girl; (ii.) name key, knife, penny; (iii.) repeat three numerals; (iv.) point out the longer of two lines.

5 years.—(i.) Find which is the heavier of two boxes; (ii.) copy a square; (iii.) repeat a phrase with ten syllables; (iv.) count four pennies; (v.) reconstruct a card cut diagonally into two pieces.

6 years.—(i.) distinguish morning and evening; (ii.) define common objects—fork, chair, table, horse, mother—by use; (iii.) copy a rhomb; (iv.) count 13 pennies; (v.) compare a number of drawings of faces from an æsthetic point of view.

7 years.—(i.) Point out right hand and left ear; (ii.) describe an engraving; (iii.) do three simple errands; (iv.) count three pennies and three halfpennies; (v.) name four colours—red, blue, green, yellow.

8 years.—(i.) Make mental comparison between fly and butterfly, wood and glass, paper and cardboard; (ii.) count from 20 to 0; (iii.) point out features missing in incomplete figures; (iv.) give the date; (v.) repeat five numerals.

9 years.—(i.) Take 2*d*. out of a shilling and give the change; (ii.) define common objects (see above) otherwise than by use; (iii.) recognise all the current coins; (iv.) name the months; (v.) answer simple questions involving problems of ordinary life—e.g., "When you have missed the train, what should you do?"

10 years.—(i.) Arrange five boxes (3, 6, 9, 12, 15, and 18 grammes) according to weight; (ii.) copy two simple geometrical designs—a prism and a Greek moulding—from memory after having seen them for 10 seconds; (iii.) criticise a number of absurd statements—e.g., "The body of an unfortunate young girl, cut into 18 pieces, was found yesterday in Hyde Park; it is thought that she killed herself"; (iv.) answer questions of similar nature but more difficult than in test for 9 years; (v.) bring three given words into two phrases.

12 years.—(i.) Resist a visual suggestion made by a series of pairs of unequal lines followed by a series of pairs of equal lines, the subject being asked which line is the longer and passing the test if he recognises the equality in the later pairs; (ii.) bring three given words into one sentence; (iii.) say more than 60 words in three minutes; (iv.) define abstract words—charity, justice, and kindness; (v.) rearrange a simple sentence, the words of which have been put out of their order.

15 years.—(i.) Repeat seven numerals; (ii.) find three rhymes for a given word; (iii.) repeat a sentence of 26 syllables; (iv.) interpret an engraving; (v.) explain an unfinished account of a common episode.

Most of the tests in each group include several examples; the abstract terms for definition, for instance, are three in number; the simple questions are three and the more difficult questions five, and so on. In such cases the test is considered to be passed if a majority of the instances are successfully dealt with. A great deal, of course, depends on the way of putting the questions and judging the results, and to secure uniformity in these points the authors give minute directions in the published description of their method.[1] The tests are for the most part of such a character that, if these directions are closely adhered to, the influence of the examiner's personal equation is comparatively slight; in fact, in the case of pupils who have learned the method directly in M. Binet's laboratory this influence is practically inappreciable.

The arrangement of the series of tests was arrived at, as mentioned above, from the average results of a large mass of observations; and it is not, therefore, to be expected that individual instances will show exact conformity with it. Intelligence involves many factors, and cannot be measured as we measure a simple character like stature; the multiplicity of the tests is a recognition of this fact, which, however unfortunate, is inherent in the nature of the case and constitutes a difficulty which we can only deal with by means of a convention. And the convention adopted in the Binet-Simon method is a very simple and reasonable one. The problem is, how are we to proceed in the numerous cases where the person under examination passes some of the tests of a given age and fails in others? In such a case the system adopted is to try easier tests till we have found the level at which the subject can do all the tests of a group; he is then adjudged to have reached the intellectual development of that age, and for the tests which he can pass in the higher age-groups he is credited with a further degree of intelligence which is estimated by counting five such tests as equivalent to a year to be added to the mental stature. If, for instance, a boy of, say, 7 years old does all the tests of his age plus three tests of 8 years and two tests of 9 years, he is considered to have attained to the intellectual development of $7 + (3/5 + 2/5 = 5/5)$ years—viz., 8 years; that is to say, he is a year in advance of his age. This, of course, is very artificial, but it is only by some such convention that the difficulty can be got over; the important thing is that the convention should be universally accepted.

In applying the method to school children the way of working is simply to try first the tests corresponding to the child's age; if he passes these the examiner tries him with the tests in the higher groups until he has obviously got beyond the subject's capacity; if, on the other hand, he fails in some or all of the tests of his age, the lower tests are tried until the level is reached where he can do all the tests. The result of each test, indicated by a + or a −, is entered in the proper place in a sheet prepared with columns showing the series of tests. It is further required that a more detailed record of the examination be taken down giving the exact answers to such tests as the definitions, questions, criticisms, and so forth, this record serving as evidence to justify the examiner's estimate of the result with each of these tests.

This method has now been employed for some years with very excellent results in a number of the primary schools in Paris as a means for detecting and classifying cases of mental deficiency. It works very well for this purpose because the tests are nearly all of such a kind that they do not presuppose school knowledge; they show the capacity of the child independently of the formal instruction which he may have received, and thus obviate the risk of taking mere ignorance or backwardness for mental defect. This is peculiarly important in the selection of children for treatment in the special schools. As the value of such institutions is engaging attention in this country, it may be of interest to note in passing that the experience of those who have worked with the Binet-Simon method rather inclines to the view that the good results claimed for the special teaching have, at least in a good many instances, been gained with children who were not in fact mentally deficient at all.

Of course, intellectual development does not proceed in a uniform way or at constant rate, and it is necessary to take account of the range of individual variation in judging the results obtained with this method. So far as an opinion can be formed from the available evidence on this point, it would appear that a child may be two years below the intellectual level of his age without being necessarily defective; an inferiority of more than two years does not seem to be made good in subsequent development.

I now pass to consider the application of this method to the measurement of intelligence in the mentally defective who are over school age. In the view of M. Binet and M. Simon an intellectual development corresponding to the average at 12 years of age is sufficient for the ordinary needs of an individual fending for himself under present-day industrial conditions. A mental capacity falling short of that level is defective, and it is proposed further to divide the mentally deficient on the basis of this method into idiots, with an intellectual level under that of 2 years, imbeciles with an intelligence corresponding to what would be normal between 2 years and 7 years, and feeble-minded (*débiles*) with a development above that of 7 years but less than that of 12 years. Accepting this definition of feeble-mindedness, we have, then, to see the results obtained from applying to the cases of this sort the tests corresponding to the different levels from 7 to 15 years. The tests are, of course, applied in exactly the same way as with the children, the starting-point being chosen according to the impression the examiner may have formed of the subject's intelligence. It is generally desirable, however, to go through a rather wider range of tests than with normal children, so as to ensure a full appreciation of the individual's powers. To show the working of the method the accompanying table will be more useful than pages of description; it gives the results found in the examination of a dozen female prisoners of what is known as juvenile-adult age—i.e., between 16 and 25. The cases have been taken from a large series of observations which are being prepared for publication in the *Année Psychologique*. Six of the prisoners were selected as representatives of the ordinary run of London working-class girls; they were good wage-earners, and were either unconvicted prisoners without criminal antecedents or had been committed only for occasional, trivial, and quasi-criminal offences. The other six were criminals who had shown indications of weakness of mind.

On looking at the table it will be observed, in the first place, that the results very generally bear out the seriation of the tests; the only apparent exceptions are the test of copying geometrical figures from memory (10 years), which is missed by several girls who succeed in the higher tests, and the test of interpreting engravings, which, on the contrary, is often done by subjects otherwise of rather low intelligence. With regard to the former of these tests I think it possible that further experience may show that it is really too difficult, but that is a matter that time must settle. With the engravings it seems to be rather different; they enter, it will be noted, into three groups of tests. At 3 years of age the ordinary child is able to name the different objects in the engraving; at 7 years he will combine the objects in a description; but it is not till he is over 12 years that he will go further and interpret the picture as a story. For instance, one of the three engravings used by M. Binet and M. Simon represents a father and son moving their very poor belongings on a hand-cart. When shown this picture the young child puts his finger on the several figures—"a man," "a boy," "a cart"; the older child says, "a man and a boy pulling a cart with furniture"; the child of 14 or 15 will bring in the dramatic note and will speak of the poverty and sufferings of the homeless family. There is some reason to think that this interpretative tendency may develop with age and experience apart from intellectual growth; I am inclined to surmise that it may be a result of an affective influence connected with puberty; that, however, is a matter for further investigation. Anyhow, apart from these two exceptions, the order of the tests conforms to expectation. And the results in the several cases also go to prove the adequacy of the method in its present form. Taking first the girls of presumably normal intelligence, it is seen that they have all succeeded in passing the level of 12 years, most of them doing, indeed, the majority of the tests for 15 years. This probably gives a pretty accurate view of the average mentality of girls of the urban working class. Turning now to the girls suspected of being feeble-minded, we find that

[1] La Mesure du Développement de l'Intelligence chez les Jeunes Enfants, Bulletin de la Société Libre pour l'Étude Psychologique de l'Enfant; Paris, F. Alcan, price 1.50 francs.

four out of the six fail to reach the level of 10 years on the Binet-Simon scale, three of them being only just over the limit of 9 years, one barely reaches 10 years, while one, and one only, shows a degree of intellectual capacity equal to that in the normal group. With this exceptional case, which is peculiarly interesting, I will deal later when speaking of the relation of these tests to the factors of mind other than the intelligence. In the other cases the value of the method in giving a clear and definite view of the extent of the deficiency was patent; three at least of the girls, though their careers suggested some degree of mental defect, showed a liveliness of manner and an appearance of alertness which could, and in fact did lead casual observers to consider them as fairly bright and to attribute their conduct to the feeble-minded criminal, it is these latter factors of mind that are of most importance. Therefore the method is to that extent an instrument of limited value in the examination of the mentally defective. On the other hand, even in such cases, it is of no small assistance to be able to separate, as it were, this one factor of the intelligence, to measure it and to assign to its deficiency the due share in the individual's inferiority. And, moreover as the factors of mind are after all intimately connected, many of the tests specially directed to the intelligence necessarily give us also some indirect indications touching emotivity and impulse. We have a striking instance of this in the exceptional observation shown in the table and referred to above—the case of the feeble-minded criminal R. P. This girl, it will be

rather to flightiness and instability than to intellectual weakness. Under such conditions an objective measure of this sort is of material assistance in clearing up the difficulty. It will certainly not be necessary to dwell on its advantages for those who are called on to satisfy lawyers and magistrates in cases where the question of mental deficiency is at issue.

The foregoing account of the method and the examples of its application will, I trust, give the reader a fairly clear notion of its merits and limitations. But before concluding, I think it may be well in this connexion to refer specially to one of these limitations which is implied in the very description of the method as furnishing a measure of the intelligence. It is designed *only* as a measure of the intelligence; it does not purport to enlighten us as to the affectivity or the will. But, of course, in regard of feeble-mindedness, at all events as the question concerns the community, as notably with reference

noted, in contrast with the other weak-minded subjects, was found to have an intelligence of fairly high level. She did, in fact, and did extremely well, all the tests for 15 years, except the repetition of seven figures, and she only just failed in that. And she was also successful in all the tests for 12 years, except that for showing the power of resistance to suggestion. In this test the subject is shown two straight lines side by side on a sheet of paper, that on the left being a little shorter than that on the right, and he is asked to point out the longer; he is next shown a second and third pair in which the length of both lines is increased, but the inequality between them is preserved, and he is asked the same question; then, when the suggestion that the right is always the longer has thus been given, he is shown three other pairs in which the lines are of the same length, and

he is considered to have passed the test if he recognises the equality. In this test R. P., who did so well in the other tests, failed, and failed most egregiously, succumbing to the suggestion as completely as the least intelligent of the feeble-minded girls. The most probable explanation of this result is that suggestibility, or, at all events, the sort of suggestibility that we are dealing with by such a test, depends largely on affectivity and impulse, and that these factors rather than the intelligence are at fault in this case. And the facts as to the girl's delinquency tend to confirm this surmise. She had committed a very silly act of arson, setting fire to a chair in the house where she was employed as a servant. She admitted the crime but could not assign any motive for it, saying merely that the idea came to her and that she acted without being able to think what she was doing. This occurred within a few hours of a more serious outbreak of fire which appears to have been due to accident, but in which, at any rate, it was not shown that she had any hand. Further, she had been subjected from childhood to a peculiar form of pathological lying which would lead her constantly to confirm and supplement by imaginary details any statement or opinion emanating from a person who had gained some influence over her. It is difficult not to connect this morbid trait and the apparently imitative act of arson with the marked suggestibility revealed in the test with the lines. I have thought it worth while to refer at some length to this girl's case as an illustration of the point I wish to make regarding the indirect value of some of the Binet-Simon tests outside the field for which they are specially intended. In the interpretation of the engravings and in several of the questions and definitions the subject's affectivity is very frequently shown in an equally instructive manner.

It should, of course, hardly be necessary to point out that this method is not in any sense proposed as a substitute for that complete clinical study on which alone an opinion of any value can be formed with regard to a case of mental deficiency. What is claimed for it is that it supplements the clinical investigation, and enables its results, so far as the factor of intelligence is concerned, to be presented with a clearness and an objectivity which must considerably enhance their value. From this point of view it is likely, I think, to be found of very real service in medico-legal practice and in the certification of the feeble-minded.

In conclusion, it remains only to express my very deep appreciation of the great kindness shown me by the late M. Binet and his fellow-workers, to whom I have been indebted for the opportunity of making myself familiar with this interesting and valuable method. M. Binet, with the generous spirit of the true *savant*, not only allowed me free access to his laboratory, but gave me most freely the invaluable aid of his advice and supervision. Dr. Th. Simon, the distinguished physician of Morel's old asylum of St. Yon, whose charming hospitality I cannot sufficiently acknowledge, gave me the opportunity of seeing in his service the application of the method to a large number of congenital defectives of all grades, and also to a number of insane patients. To Mlle. Giroud, secrétaire de la Société Libre pour l'Étude Psychologique de l'Enfant, I am indebted for instruction in the details of the various tests, and I have to thank M. Vanney, the enlightened headmaster of one of the principal primary schools in the district of La Villette, for allowing me to practise the method on a large number of his pupils of different ages. I have also to acknowledge the kindness of the well-known philanthropist, M. Henri Rollet, who permitted me to test the intelligence of several adolescent criminals in one of his after-care homes. And finally I have to thank the Prison Commissioners for granting me the period of special leave during which I was enabled to undertake this study.

H.M. Prison, Holloway, N.

THE (Biennial) Health Conference and Exhibition, 1912, will be held at the Royal Horticultural Hall, Westminster, from June 24th to 27th, under the patronage of H.R.H. Princess Christian of Schleswig-Holstein, in coöperation with the National Health Society. The promoter and organiser is Miss R. V. Gill, 35, Ludgate-hill, London, E.C.

PHARYNGEAL SUPPURATION: COURSE AND DIRECTION OF VARIOUS TYPES.

BY GEORGE W. BADGEROW, F.R.C.S. EDIN.,
SURGEON TO THE THROAT HOSPITAL, GOLDEN-SQUARE, LONDON.

IN dealing with this subject it is advisable to consider first the anatomy and physiology of a region so intimately concerned with all the vital processes, and then to apply well-established principles of surgery and pathology without being led either by the specialist's tendency to magnify fine clinical distinctions or by the general surgeon's desire for differences which, although not prominent, may be of great importance in diagnosis, prognosis, and treatment. It is also advisable in giving a comprehensive description of any surgical condition that we should avoid the use of terms which, though sanctioned by ancient usage, are not scientifically accurate, and may be misleading. Such terms as "quinsy" and "croup," for instance, should be relegated to the past. There is some danger, however, of substituting for these terms others which are more impressive, but which are, after all, only more evidences of our want of knowledge of the essential nature of the disease with which we have to do. In this category comes the expression "retro-pharyngeal abscess," an expression which neither describes nor defines the several conditions to which it is commonly applied.

The methods usually employed by medical writers in classifying diseases may be either anatomical or clinical. In classifying suppuration in the region of the pharynx, while it is a great advantage to possess a wide experience of the various and varied appearances which present themselves to the surgeon engaged in their treatment, only a thorough grasp of the anatomy and physiology of the region will furnish the principles which go to form reliable knowledge, and which will enable him to apply his technical skill in a manner calculated to bring the greatest amount of relief to the sufferer.

Points for Consideration in the Anatomy and Physiology of the Pharynx.

The most important structure to study in connexion with the pharynx is the strong aponeurosis which, known as the pharyngeal aponeurosis, forms a kind of fibrous bag, around which are applied the structures required for the performance of the important functions concerned and on which they act. This aponeurosis is attached above to the under surface of the basal portion of the occipital bone, immediately in front of the pharyngeal tubercle; then to a line extending along the under surface of the petrous portion of the temporal bone as far as the anterior border of the jugular foramen; then to the inner end of the Eustachian tube and along the border of the internal pterygoid plate, to the pterygo-maxillary ligament and to the posterior end of the mylohyoid ridge on the lower jaw. From this the aponeurosis passes down the side of the tongue to the hyoid bone. Here it ends, but under the name of the thyrohyoid membrane is continued to the middle of the posterior surface of the thyroid cartilage, where it becomes merged in the lining membrane of the larynx.

Posteriorly the bag formed by the pharyngeal aponeurosis is complete, and forms a continuous layer of tissue from the base of the skull to the sixth cervical vertebra, where it joins the fibrous coat of the œsophagus at the level of the cricoid cartilage. The soft palate may be considered as part of the pharynx, and the fibrous aponeurosis, which is clothed by mucous membrane in front and behind by both muscles and mucous membrane, forms an integral part of the pharyngeal apparatus and is intimately concerned in suppurative processes, especially in the neighbourhood of the tonsils. The soft palate when drawn back acts as a curtain separating the mouth from the naso-pharynx and nose.

Superficial to the pharyngeal aponeurosis is the mucous membrane, which is continuous with that of the several cavities or canals opening into it, but which has a distinct character of its own. Numerous mucous glands are to be found scattered over its surface, while an abundance of lymphoid tissue, which is especially marked during the earlier years of life, is responsible in great measure for the ease with which pathogenic micro-organisms produce their effects within its substance.

The lymphoid tissue is mainly collected into a series of aggregations called "tonsils," which form a ring extending from the roof of the pharynx down the sides of the faucial isthmus to the dorsum of the tongue. Lying beneath the body of the sphenoid is the collection of lymphoid tissue known as the pharyngeal or Luschka's tonsil. With this the name of "adenoids" is associated when it is hypertrophied; a smaller collection is that at the posterior lip of the Eustachian orifice and in the fossa of Rosenmüller lying above and behind it. At the sides of the buccal aperture, between the anterior and posterior pillars of the fauces in the recess known as the tonsillar recess, is the faucial tonsil or tonsil proper, while on the pharyngeal aspect of the dorsum of the tongue, lying between that and the epiglottis, is the lingual tonsil, which differs from the others in its relative insignificance during the years of childhood.

Having considered the aponeurosis and its overlying mucous membrane, we next have to deal with the muscles which lie outside the aponeurosis in a space between that and the strong layer of tissue known as the prevertebral fascia. This space has been described as the "retro-pharyngeal space," a description which is too vague, especially when we come to consider suppuration in the pharynx as a whole. We must bear in mind that there is an anterior as well as posterior and lateral surfaces to the pharynx, and we shall thereby be enabled to include various important forms of suppuration beneath the root of the tongue which lie in the same plane as the space in which the constrictors of the pharynx lie. The constrictors are three—the superior, middle, and inferior, which are associated in deglutition by the stylopharyngeus, the stylohyoid, the palatoglossus, and palatopharyngeus, together with the muscles of the soft palate. These muscles are important in connexion with suppuration, not so much from the point of view of cause as of effect, for their involvement gives rise to one of the most characteristic symptoms of that affection—viz., dysphagia or difficulty in deglutition.

Posterior to the muscle lies the strong prevertebral fascia, which stretches across the neck from the deep surface of one sternomastoid to that of the other, and thus separates the anterior surface of the bodies of the cervical vertebræ and the ligaments and muscles attached thereto from the muscles of the pharynx. Posterior to the prevertebral fascia on the rectus capitis anticus major lies the post-pharyngeal gland, which may caseate and form an abscess presenting on the pharyngeal wall. Behind these several structures we come to the bodies of the first six cervical vertebræ, and thus complete the list of the anatomical factors likely to be involved in suppuration of the pharynx.

Etiology of Pharyngeal Suppuration.

The etiology of suppuration in the region of the pharynx resolves itself into a question of bacteriology, and when we consider that in apparently healthy throats there are found, among other numerous pathogenic bacteria, the tubercle bacillus, the diphtheria bacillus, streptococci, staphylococci, pneumococci, bacillus coli communis, the micrococcus catarrhalis, and various forms of leptothrix, the only wonder is that inflammations and suppuration are not more common than they are. The structure of the lymphoid tissue itself predisposes to the entrance of micro-organisms, for in the epithelium of the crypts there are gaps which permit of the passage of leucocytes, and *a fortiori*, of the much smaller schizomycetes which set up disease processes. Placed at the entrance to the respiratory and digestive systems, and intended evidently by nature to act as a protecting filter, the tonsillar tissue must be admitted to fail to a great extent in the purpose which it is supposed to fulfil.

As factors predisposing to suppurative processes in the pharynx may be mentioned such causes of chronic irritation as smoking, alcoholism, and syphilis. The exanthemata, especially measles and scarlet fever, also predispose to infection, and the influenza bacillus by its effect on the accessory air sinuses is responsible for many cases of suppuration owing to the discharge into the naso-pharynx of the products of acute and chronic sinusitis. Middle-ear disease through its connexion with the Eustachian tube is liable to produce suppurative pharyngitis.

The mechanical causes of suppuration in the pharynx are foreign bodies, such as fish bone, chicken bones, rabbit bones, while such an object as a broken pipe-stem has been extracted from a tonsil, where it lay embedded for weeks. In children, wounds from pointed sticks give rise to suppuration not infrequently; while in lunatics and persons of suicidal tendencies we may have to deal with the results of infected wounds inflicted by knives, pieces of glass or metal, and by bullets.

Classification of Suppuration in the Pharynx and its Neighbourhood.

The only scientific classification of pharyngeal suppuration is an anatomical one based on the tendency which pus usually exhibits of travelling in the planes of cellular tissue. One is not unmindful of the possibility of this, as of all other disease processes, extending from the original seat to adjacent strata, but we should always endeavour to have before our mental purview a definite conception of a starting-point from which to follow the course and progress of the disease in each individual case. Suppuration originating in each of the layers which compose the pharyngeal wall has a definite character of its own, which often will enable the careful investigator to recognise and deal with it effectually as soon as the time for action arises.

The classification which I would propose is as follows. Pharyngeal suppuration, according to its seat of origin, may be: (1) Lymphoid; (2) submucous; (3) subaponeurotic; (4) prevertebral.

1. *Suppuration arising in the lymphoid tissue of the pharynx.*—Although this is by far the commonest seat of infection, it is seldom that we find any large collections of pus in this layer of the pharyngeal substance. In acute lacunar tonsillitis the crypts may contain pus which either confines itself to the separate lacunæ or spreads as a false membrane over the tonsillar surface. Occasionally one finds as a result of parenchymatous tonsillitis the whole tonsil becoming smooth and rounded, forming a localised abscess. In my experience I have only observed a slight number of cases in which suppuration resulted in a pure tonsillar abscess. It is rarer still in the pharyngeal and lingual tonsils. In Vincent's angina one sometimes finds a membrane due to staphylococcus infection which may be mistaken for diphtheria.

2. *Suppuration originating in the submucous tissue of the pharynx.*—This is the form of suppuration which most often presents itself to the surgeon, and is best exemplified by the well-known peritonsillar abscess to which the popular designation of quinsy is applied. It is characterised by a rapid infiltration of the loose submucous tissue over an extent of surface varying with the virulence and duration of the infective process. In the case of peritonsillar abscess the local manifestations are most marked in the soft palate, but may, if unchecked, spread over the whole of the submucous layer of the pharynx. In the form of pharyngeal suppuration described by Senator under the name of "acute infectious phlegmon" the disease may run its course and cause death in four or five days, either from œdema of the larynx or from the severity of the constitutional symptoms. Here the deeper layers of the pharynx may be practically free from pus.

The most prominent symptom in all submucous affections is dysphagia. This is due partly to the presence of the swelling, but mostly to the pain caused by pressure on delicate nerve endings. Trismus is also largely reflex in order to prevent pain.

3. *Suppuration arising in the subaponeurotic layer of the pharynx.*—To suppuration occurring in the space between the pharyngeal aponeurosis and the prevertebral fascia some writers would confine the term "retro-pharyngeal abscess." This, however, appears to me to favour the looseness of thought which in the past has done so much to prevent a clear understanding of the various processes which may result in an abscess in this region.

Adhering to the classification proposed above, the term "subaponeurotic suppuration" would include not only an abscess originating in the deep cervical glands and presenting at the back of the pharynx, but also the particular form of submaxillary phlegmon known as "angina Ludovici," while it would exclude an abscess the origin of which was due to caries of the cervical vertebræ or caseation in the post-pharyngeal gland.

4. *Prevertebral suppuration.*—The last of the forms of suppuration in the pharynx is that with which the name of retro-pharyngeal abscess is almost always associated in the mind of the general practitioner. Arising not in the

pharynx but as an abscess either of the vertebræ or of the lymphatic glands adjacent thereto, it has in reality no right to be designated as pharyngeal, and the name "prevertebral" ought, I think, to be employed instead to describe this condition. A prevertebral abscess may, of course, arise as a result of a penetrating wound of the pharynx, just as an abscess of the lung may result from a stab of the chest-wall, but in the latter case we describe the disease in association with the organ in which it is found. The subject of caries of the cervical vertebræ and of caseation of the post-pharyngeal glands, therefore, while of great interest to the surgeon, need not be exhaustively treated of here, for it is a subject which has been adequately dealt with by more than one writer. One or two points in connexion with diagnosis may be referred to. The history alone will do a great deal to enable us to distinguish the other three forms of suppuration from this one. The sufferer is often a child or young adult and the accompanying signs of spinal caries are mostly fairly evident. The duration, the absence of fever, the lack of muscular rigidity except where actual deformity exists, and the slow onset of dysphagia will decide us in making a diagnosis. The pus may present either in the middle line or laterally, and the presence of fluctuation will distinguish from sarcoma, while there is no superficial bleeding when the swelling is touched, as in the latter disease. The prognosis depends upon the extent of the spinal mischief and to some extent on the care with which the treatment is carried out, for although the symptoms may not appear urgent the tendency for the pus to track downwards, and so beyond the reach of the surgeon, and the risk of secondary infection if the abscess opens into the pharynx are considerations of weighty import in dealing with a case of this kind.

Brook-street, W.

A CASE OF ACUTE MYELITIS WITH OPTIC NEURITIS (NEUROMYELITIS OPTICA).

BY ERNEST F. CLOWES, M.R.C.S. ENG., L.R.C.P. LOND.

With Remarks by Dr. FREDERICK TAYLOR, *Consulting Physician to Guy's Hospital.*

THE following case of this interesting form of disease came under my care last year, and I have thought it worthy of publication. Dr. Frederick Taylor, who published a case of the kind some years ago in the *Guy's Hospital Reports*, Vol. LIII., p. 45, has very kindly added some remarks as to the literature of the subject.

The patient was a single woman, aged 39 years. She had two brothers and two sisters. The brothers were both healthy, but very sensitive and highly strung men. One of the sisters was very neurotic and had frequent hysterical attacks, and the other was mentally deficient. The father had died from senile decay at the age of 90 years and the mother from cerebral hæmorrhage when 78 years old. By all her family the patient was always regarded as very capable and industrious, and she was endowed with a strong personality which clearly dominated the whole circle. She came home from her situation to attend her mother's funeral, and remained at home afterwards to assist her sister, who was greatly pressed with her business; and to complete an order the patient and her sister worked for two whole nights. When the work was finished the patient delivered it, and coming home was caught in a severe rainstorm and got wet through. She had a hot bath and went to bed at 7 P.M.

On the following morning (July 14th) the patient was awakened at 2.30 A.M. by a severe "stabbing" and "burning" pain in the spine "just below the shoulder-blades." The pain radiated round to the front of the chest; it was agonising. Hot flannels and other means were tried, but the pain persisted in severity, and I was called to see her at 5 30 A.M. I found her sitting up in bed absolutely rigid and grasping the sides of the bedstead with each hand, thus keeping the body and neck perfectly straight. Her eyes were fixed and looked directly forward. She was quite sensible, and when I asked her what she complained of she said that if she moved in the slightest degree she had intense pain just below the "shoulder-blades." I proceeded to examine the back, but the movement of the bed-clothes caused her to shriek out with agony. The pulse was rather full, but regular, 73 to the minute, and the respirations were 18 to the minute. I injected hydrochlorate of morphia (gr. ¼) and waited to watch its effect. In less than 15 minutes the patient said she felt drowsy, and moved her head a little to the right side, and asked for some milk; she then gradually levered herself down into the recumbent position and dropped off to sleep. I saw her again at 11.30 A.M. and found her still lying down in the bed. She had had five hours sleep, and was fairly free from the pain in the back, so that I could make a more detailed examination. She did not look ill, and had a bright complexion. She complained of not being able to see clearly with the right eye, and said the left was also very weak. Round her waist she said there was a feeling as if a broad elastic band was applied very tightly, and the skin over this area was so tender that she could not bear the weight or touch of the bed-clothes. The right leg was everted and she said it felt weak; there was marked loss of power in this limb. The left leg was not everted, and apparently had normal power, as she could flex it against considerable pressure. There was no loss of power in the arms and a good strong grasp was present in each hand. There were no sensory changes in the legs or thighs; the patient was quite sensitive to the touch of a feather or pin anywhere, and could locate accurately the slightest touch. Over an area in front limited above by a line drawn round the chest about an inch below the nipples, and below by a line drawn round the abdomen 3 inches above the umbilicus, there was marked hyperæsthesia; touching the patient with a feather anywhere over this area, back or front, caused intense pain. Over the face, head, arms, chest, and back sensation was normal. In the right limb the knee-jerk was absent. Plantar reflex was also lost, but ankle clonus was very marked. In the left limb a very faint knee-jerk was present, but no plantar reflex and ankle clonus could be obtained. If either foot was flexed the foot remained so for a short time, the muscles slowly relaxing. There was no wasting of muscle in the legs, arms, or hands. The electrical reactions could not be tested. The bladder and rectum were unaffected. Of the special senses hearing was perfect. When tested for smell with the left nostril closed the patient could not detect the smell of ordinary scent (lavender water) or even the smell of an onion. With the right nostril closed she could but faintly tell the difference between the two scents mentioned. In taste a little liquor strychninæ applied to the left half of the tongue could not be appreciated, but when it was applied to the right half she could easily distinguish the bitter taste. Sugar and salt when applied to each half of the tongue could be distinguished on the right half but not on the left. Motion and tactile sensation in the tongue were normal. The patient could distinguish heat from cold when tried in the lower part of the body or limbs. The pupils were equal and they reacted to light and accommodation, there was no oculo-motor paralysis, and apparently no limit to the visual field except in the right eye. The right disc was blurred and indistinct but the left only slightly so. The urine was acid, of specific gravity 1016. No albumin or sugar was present.

July 16th: The patient had passed a very restless night. The pain in the back was most severe. She had tried to get out of bed and had badly bruised the left shin and knee. Sensory changes had developed since the day before and she could not tell the touch of a feather from that of a pin. When the left leg was touched she said it was the right. The left leg had lost its power and it fell quite limp when raised and allowed to fall. The reflexes remained the same as on the day before. She said her eyesight was more dim. The bladder and rectum remained unaffected and the band of hyperæsthesia remained the same in extent as before. The temperature was 100·4° F. From the 17th to the 21st the patient's condition remained unchanged.

July 22nd: The patient had had a bad night, and the motor symptoms had greatly changed. There was now almost total paralysis in the lower limbs and the knee-jerks were absent. Plantar reflexes could not be obtained, but marked ankle clonus was present. There was total anæsthesia over the lower limbs, extending upwards almost to the umbilicus. Breathing was almost entirely abdominal. The bladder and rectum remained unaffected. The arms, neck, and head could be moved easily and apparently without any loss of power. Both optic discs remained very blurred,

and the patient complained of great dimness of vision. She was moved to a cottage hospital, and all her symptoms slowly increased. On the 27th she had retention of urine and the catheter had to be used. Marked dysphagia set in, and she died at 5.30 P.M. suddenly while trying to swallow some milk. No post-mortem examination was allowed.

REMARKS BY DR. FREDERICK TAYLOR.

The case above recorded is an instance of a combination of lesions which excites interest, partly on account of its relative rarity, and partly from the difficulty in explaining the occurrence of the inflammatory lesion in two parts so remote from one another. When I published a case of the kind in the *Guy's Hospital Reports* in 1896 I was able then to give a bibliography of 25 references. Other cases have been since published, and in his thesis for the Doctorate of Medicine of Paris, 1907, Dr. H. J. T. Hillion gives 49 references, and reports more or less fully 45 cases dating from 1879 onwards. My own case is not given or referred to by him.

The name "la neuro-myélite optique," or neuromyelitis optica, was first proposed by Devic in 1894, and under that name recent cases have generally been recorded. I do not regard it as a happy one, since the application of the epithet "optic" to the substantive "myelitis" makes sheer nonsense; but it is very difficult to find a suitable alternative. Some French writers speak of it as Devic's disease—*maladie de Devic*. But after all there is not much more in it than the apparently accidental co-existence of optic-neuritis and myelitis; accidental because an explanation of the association of optic neuritis with myelitis is not so easy to find or suggest as that of an association of optic neuritis with a cerebral lesion. Hillion says under "Definition," "The name, acute neuromyelitis optica, is employed for a clinical syndrome characterised by a diffuse myelitis, most often acute, preceded, accompanied, or followed by an optic neuritis of parallel evolution."

Thirteen years previously to the publication of Hillion's treatise Gault had published his Doctor's thesis, at the University of Lyons, on the same subject, based on a fully reported case under Devic's care. The conclusions do not materially differ from those of Hillion, and very little seems to have been added in the interval between the appearance of the two theses.

As a result, the following propositions may safely be made.

Double optic neuritis is occasionally seen in association with acute myelitis. The optic neuritis generally precedes the myelitis by some days or weeks; but it may occur simultaneously, or first appear some days after the onset of the myelitis. The neuritis is in some cases only shown by a temporary amaurosis; in others there is obvious papillitis. The myelitis is, as a rule, not different in its symptoms and course from myelitis unassociated with an ocular lesion. The prognosis of the case must depend on the severity of the myelitis, and the mortality has been about 50 per cent. The optic neuritis has often subsided, and vision has been recovered.

There is no satisfactory conclusion as to the nature of the lesion; most authors are inclined to regard it as infection attacking the cord and the optic nerve separately. The evidence is strongly against the spread of infection, or inflammation, from the spinal cord to the optic nerve.

Pathologically, the lesion of the cord is seen to be a diffuse or disseminated myelitis, affecting either the cervical or dorso-lumbar region, or both; and histologically, in some cases, numerous endothelial cells undergoing fatty degeneration have been found around the vessels in the affected parts. To these importance has been attached by some authors, but others are satisfied that such elements are not peculiar to those cases. In a few of the fatal cases some indications of encephalitis have also been present. In two cases by Auerbach there was clinical evidence of cranial nerves being involved; and in the present case there were noted a diminution in the sense of smell and loss of taste in the left half of the tongue. A reference to a few cases will show some of the points of difference among them.

In my own case vision declined and was lost in the course of two days, and paralysis of the legs began a fortnight later. No papillitis was ever observed, but the optic discs were atrophied three months later, and I inferred that there had been a retrobulbar neuritis. Some improvement nevertheless took place in the patient's vision for a time to the extent of her being able to see objects, but it was still much impaired 12 months later. The arms were slightly involved, and hyperæsthesia of the chest wall was present at the upper border of the fourth costal cartilage. The patient died after 14 months' illness. There was no post-mortem examination.

The case which forms the subject of this paper was much more rapid. The disease was an acute ascending paralysis, commencing with indications of meningitis in the form of acute pain and spinal rigidity. Vision was impaired on the following day, and on the day after this evidence of slight papillitis, more on the right side, was observed. The upper limit of hyperæsthesia was one inch below the nipples. On the ninth day of illness the breathing was almost entirely abdominal, but the arms could be moved apparently without any loss of power. On the fourteenth day marked dysphagia set in, and she died while attempting to swallow fluid.

Dr. T. D. Acland read a case in June last before the Association of Physicians of Great Britain and Ireland. He has not yet published it, but has kindly allowed me to mention the following main facts. The patient was a man, 38 years of age, who was admitted into St. Thomas's Hospital on Nov. 12th, 1910, complaining of total blindness in both eyes, partial loss of power in both legs and in the left arm, loss of sensation over the lower part of the body and legs, and loss of control of the sphincters. The illness had begun eight days previously. The symptoms pointed to a considerable lesion of the spinal cord, extending, with intermissions, from the cervical enlargement to the lumbar enlargement, and affecting both grey and white matter. The right fundus showed thrombosis in, and hæmorrhage from, the retinal vessels, and it was thought probable that there was thrombosis of the vessels spreading across the chiasma. Two months after the onset the right disc showed signs of post-neuritic atrophy, and the left showed signs of primary atrophy. Three months after the onset the patient left the hospital, with no obvious loss of power in the legs, and with no difficulty in micturition; but he was completely blind.

Dr. James Taylor and Dr. J. Collier published a series of 12 cases of ocular lesions associated with spinal disease, in *Brain*, 1901, p. 532. Five of these are included by Dr. Hillion in his thesis as cases of optic neuromyelitis. In the other seven cases the spinal lesions were: Chronic myelitis, 1; spastic paraplegia, 1; caries of the spine, 1; fracture-dislocation, 1; hæmatomyelia, 1; and tumour of the spinal cord, 2. The interest of these latter cases is that they show that the spinal lesion associated with the optic neuritis is not necessarily an acute inflammation; and hence the difficulty of explaining the occurrence of the ocular lesion in neuromyelitis optica is increased. Dr. James Taylor and Dr. Collier show that the spinal lesion frequently, if not always, reaches as high as the upper dorsal or cervical region of the cord.

Wotton-under-Edge.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held on March 14th at Caxton House, Westminster, with Sir Francis H. Champneys in the chair. A letter was considered from the medical officer of health for Devonport inquiring: (1) As to the giving of a certificate of stillbirth by a midwife; (2) as to the attendance at a confinement of a pupil midwife not under the immediate supervision of a certified midwife; (3) as to whether, in the opinion of the Board, a midwife's superficial examination of the dead body of a child entitles her to certify that the child has not breathed. The Board directed that the medical officer of health for Devonport be informed that the replies to his questions are as follows: (1) That the midwife was wrong in giving a certificate of stillbirth as she was not present at the birth; (2) that the trainer is responsible for each case attended by a pupil; (3) that this question is covered by answer (1). A letter was considered from an inspector of midwives as to the extent of the obligation to attend to the comfort of the mother and child entailed on a midwife by Rule E. 11. The Board decided that the reply be that the midwife is responsible if the baby is not properly cared for.

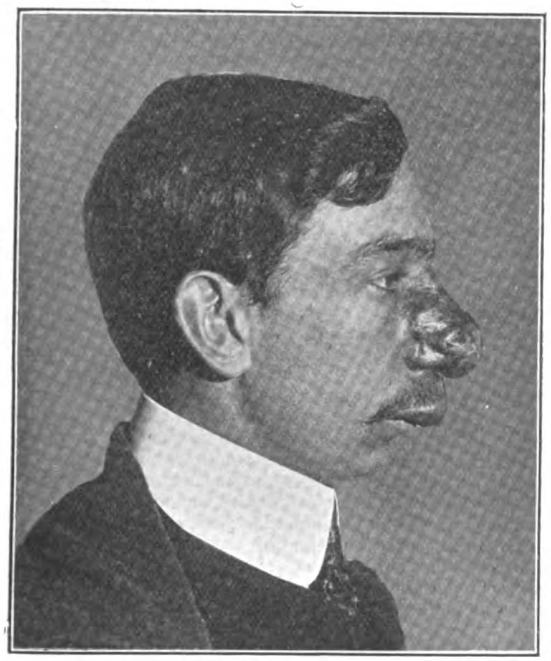
DECORATIVE SURGERY.

BY W. H. BATTLE, F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL.

THE following three cases illustrate the importance of this branch of the surgeon's art to which allusion was recently made in an annotation in THE LANCET.[1] They also illustrate the fact that there is usually more than the mere appearance of the patient to be considered. In the two cases with vascular growths it was necessary to operate because of the increase in the disease; whilst in the cirsoid aneurysm there was also the danger to the life of the patient because of the liability to hæmorrhage which so often proves fatal when these growths have become large. In the third case removal was imperative to enable the man to follow his occupation.

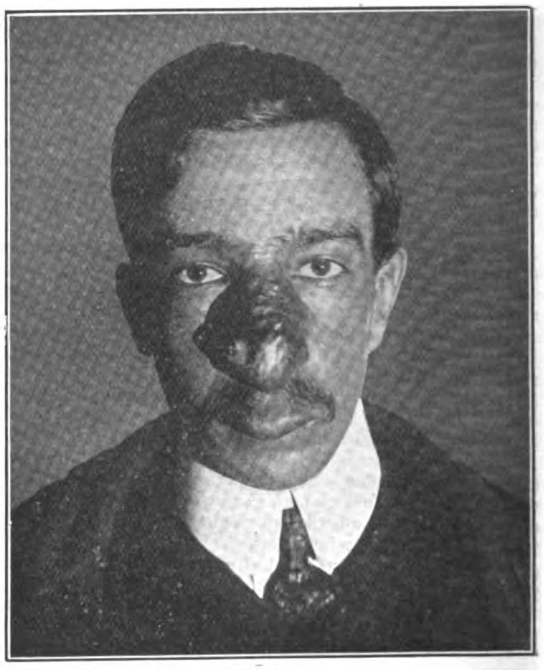
CASE 1.—In the year 1906 a patient was sent to me with a letter from Dr. P. Clennell Fenwick, of Wanganui, New Zealand. This patient, aged 24 years, had considerable disfigurement of his face in consequence of a congenital hæmangioma which affected it and the upper lip. He was not a man of means, and in order to assist the sum which he was able to get together for the expenses of the trip he offered himself as a steward for the voyage. The agents of the shipping company refused to allow him to take the post because it was thought that the passengers would be upset by his appearance. A few days after his arrival he was admitted to St. Thomas's Hospital, and remained there from June 18th to Sept. 12th, some weeks after which he returned to New Zealand.

FIG. 1.



Pulsating nose, side view.

FIG. 2.



Pulsating nose, front view.

The reproductions of the photographs (Figs. 1 and 2) show very well the general appearance of the nose. This caused him no pain, but he was much worried by the observations which were made about his appearance by strangers, and he found it difficult to get employment. On more than one occasion he had suffered from hæmorrhage. The nose was very large, appeared bulbous, was of a purplish-red colour, with some superficial dilated veins, and visibly pulsated all over. To the touch it was rather compressible, diminishing much in size, and rapidly filling out again when pressure was relaxed. The condition extended upwards between the eyes and downwards into the mid-portion of the upper lip, which was large and prominent. There was not much change in the mucous membrane of the nostrils.

On July 11th ligatures were applied to the external carotid, the superior thyroid, and the facial arteries on both sides. After these wounds had been closed the whole of the disease of the nose was cut away, leaving only the bony and cartilaginous framework. On the 15th electrolysis of some outlying portions of tissue was done. On the 27th this operation was repeated and the central portion of the lip was excised with part of the columella nasi. On August 3rd a flap of skin from the forehead was turned down after the Indian method to cover the granulating surface. It was adapted by its size and saddle-shape to cover the granulating surface, but no columella nasi was required, it being sufficient to excise a median portion, as the whole columella was too thick. On the 27th the denuded surface was grafted.

Dr. Fenwick has recently told me that the result of the operation at the present time is very satisfactory, as the man is pleased with his improved appearance and is able to make a living in an occupation which takes him much amongst strangers.

CASE 2.—In the case of the baby (shown in Figs. 3 and 4), under care in the children's ward, St. Thomas's Hospital, 1909, the nævoid growth gave him a wonderfully ancient appearance. It was, however, of limited extent, without pulsation, and yielded to treatment by electrolysis and the application of nitric acid. Nævoid growths on the nose are not very uncommon, but they do not often produce such a grandfatherly aspect as that which we found here.

CASE 3.—Figs. 5 and 6 show the common disease of lipoma nasi, or rhinophyma, and is only interesting from the fact that the patient had to have an operation. He was a tailor, and said that he did not care about his personal appearance, but was unable to work because his nose prevented his seeing to thread his needle. For some time he had managed by holding his nose down and his hands high up, but recently this expedient had failed him, and he was obliged to seek surgical assistance. The disease was treated in the usual manner, and he was much pleased with the result.

[1] THE LANCET, Jan. 6th, 1912, p. 38.

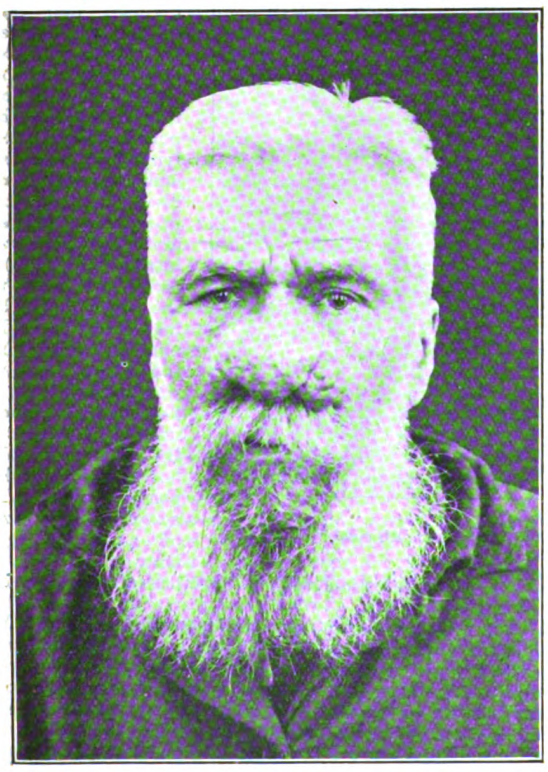
FIG. 3.

Nævus of nose, side view.

FIG. 4.

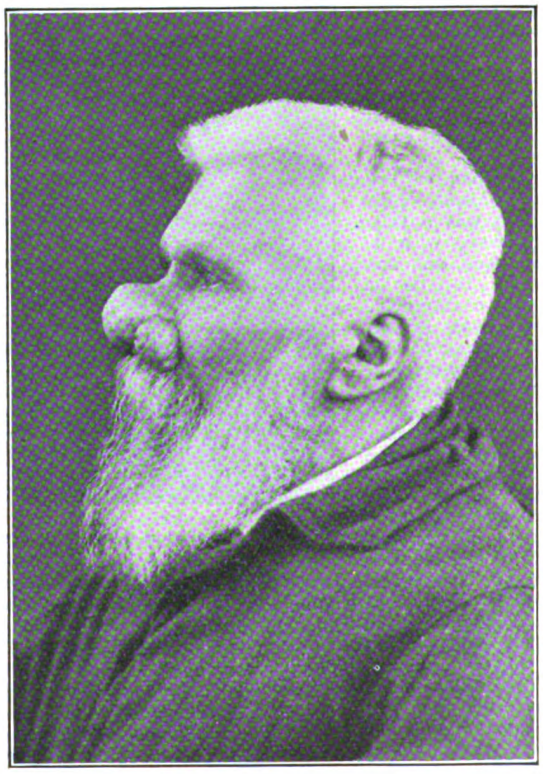
Nævus of nose, front view.

FIG. 5.



Rhinophyma, front view.

FIG. 6.



Rhinophyma, side view.

Note.—The chief interest of these cases lies in the extent of the disease which is shown in the illustrations. It is a matter of regret that I am unable to produce photographs of the patients as they appear now, but from the notes it will be seen that the result in the case of the adults was satisfactory, whilst in the second case there has been no return of the nævus and the mother appears satisfied.

A CASE OF PHARYNGEAL DIVERTICULUM.

BY E. B. WAGGETT, M.A., M.B., B.C. CAMB.,
SURGEON TO THE NOSE, THROAT, AND EAR DEPARTMENT, CHARING CROSS HOSPITAL;
AND
EDWARD D. DAVIS, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT TO THE NOSE, THROAT, AND EAR DEPARTMENT, CHARING CROSS HOSPITAL.

THE number of reported cases of pharyngeal diverticulum is small, and the points of interest in the treatment of this case make it worthy of publication.

The patient, a labourer, aged 40, formerly a soldier, complained of difficulty in swallowing, and he stated that for the past five years he had always returned a small quantity of food after each meal. These symptoms gradually increased in severity, and for the last three months he had noticed a swelling on the left side of the neck, which increased in size after taking food. If he compressed the swelling about an ounce of food and saliva regurgitated into the mouth, and this had increased in quantity during the past few months. Recently the difficulty in swallowing had become more marked towards the end of a meal, being distinctly noticeable after the first few mouthfuls. In addition he volunteered the statement that he was "short of breath" after food and on slight exertion.

Condition on examination.—The patient was a tall, thin man, with a long neck, and appeared to be a healthy countryman. There was fulness and bulging of the left sterno-mastoid muscle immediately below the level of the cricoid cartilage, and the swelling became more marked after taking food. On giving the patient food he was able to swallow the first few mouthfuls without trouble, but in order to take more he had to turn the head to the right and to flex the neck. By compression of the pouch he was able to return about half a teacupful of food. Examination by the laryngoscope showed a normal larynx and trachea.

Radiogram taken by Dr. Ironside Bruce after a bismuth meal.

The patient was then examined by the œsophagoscope. The pouch was emptied by compression, and the patient directed to wash it out by drinking and regurgitating water. The pharynx was then swabbed with a solution of 20 per cent. cocaine and adrenalin, and the œsophagoscope was introduced. At the level of the upper edge of the cricoid cartilage the orifice of the œsophagus was seen as a narrow slit, but on the posterior wall a larger opening was seen through which the tube passed easily, but after this point the view was obstructed by frothy saliva.

The tube could be passed another three inches, but was then obstructed. From this it was gathered that the pouch was about three inches in length. The tube could be passed into the œsophagus and no stricture was observed, but at this stage the patient became intolerant.

The radiogram taken after a bismuth meal, by Dr. Ironside Bruce is depicted, and was most valuable. The pouch was shown on the left side of the œsophagus and extended behind the clavicle.

With the X ray screen a flexible bougie which had been introduced could be seen in the œsophagus, and was obstructed about 10 inches from the teeth. The first few mouthfuls of the bismuth meal could be seen as large boli passing rapidly down the œsophagus, but as the pouch filled the boli became smaller and swallowing became more difficult.

Operation.—On Oct. 8th, 1910, Mr. Waggett operated and invaginated the pouch, a method described by Professor Girard.[9] The pouch was previously washed out by the patient swallowing and regurgitating boric lotion; he emptied the pouch by compression of the neck immediately before taking the anæsthetic. Chloroform was given without the administration of morphia or atropine.

An incision 4 inches in length, with its centre opposite the cricoid cartilage, was made along the anterior border of the left sterno-mastoid. The anterior border of the sterno-mastoid was defined and the muscle retracted outwards. The anterior belly of the omo-hyoid was then divided, and the dissection continued with Kocher's director between the carotid sheath and the trachea. The pouch was exposed lying free in a sac and requiring no dissection. At this point a silver urethral catheter was introduced by the mouth, but owing to the curve of the instrument it could not be passed into the pouch, and it was replaced by a flexible olive-headed bougie. The end of the instrument could be easily felt in the pouch, which was about the size of a hen's egg, and resembled a piece of small intestine with a net-work of veins on its surface.

It was found to open from the posterior wall of the œsophagus above the level of the cricoid constriction and opposite the cricoid cartilage. After careful isolation it was invaginated and pushed downwards into the œsophagus. There was no stricture of the œsophagus, and two fingers could be passed downwards with ease. When the pouch had been invaginated, its orifice appeared to be a small slit less than one inch in length in the wall of the œsophagus. If the patient vomited the pouch was extruded, and in order to produce vomiting the anæsthetic was stopped and the fauces tickled. Finally, the pouch was again invaginated and the slit-like orifice in the wall of the œsophagus was closed by one layer of four interrupted silk sutures. The patient was again made to vomit and the pouch proved to be secure. It remained in the œsophagus and was not again extruded. A

drainage-tube was inserted at the lower end of the wound, which was closed by deep and superficial stitches. A Symonds's œsophageal tube was passed through the nose into the stomach, but it was vomited on recovery from the anæsthetic. The tube was not reintroduced because its presence promoted vomiting and worried the patient.

The next day the patient swallowed 4 oz. of water without discomfort and was ordered soup and beef-tea. In addition he was given rectal enemata of glucose and saline, and from this point he made an uninterrupted recovery. The wound healed by first intention, the drainage-tube was removed on the fourth day, the patient got up on the sixth day, and he left the hospital on the fourteenth day.

On Jan. 27th, 1911—i.e., 3½ months after the operation—the patient was seen again, and said he could swallow anything without difficulty. He was examined with the laryngoscope and œsophagoscope, and the invaginated pouch could be seen as a pale polyp projecting upwards immediately behind the cricoid cartilage. It was proposed to admit the patient and to remove the polyp with the cautery snare introduced through the œsophagoscope. The patient was to have been shown that afternoon at the Polyclinic, but unfortunately he disappeared.

In August, 1911, the patient returned complaining that he had sneezed violently and felt "something break in his neck," and after this occurrence the old symptoms of difficulty in swallowing returned. The swelling of the neck was noticed, and a radiogram, following the bismuth meal, showed a pouch in the same position as before and of about the same size.

Second operation.—Mr. Waggett operated again on Oct. 5th, 1911, and on this occasion the pouch was isolated without difficulty. It was slightly adherent to the surrounding parts, but in other respects had exactly the same appearance as on the first occasion, being covered by the close network of veins, which had somewhat limited the number of stitches inserted at the invagination operation. The neck of the pouch was clamped and divided between forceps. The stump was carefully stitched with a continuous silk stitch and then buried by a layer of Lembert sutures. The wound was closed and drained as before.

The after-treatment consisted of keeping the patient in the prone position with the head low. He was fed by rectal enemata for three days and then allowed to take water by the mouth; this was not followed by leakage through the wound. On the sixth day he was given soft solid food. He made an uninterrupted recovery, and the wound healed by first intention, with the exception of the point where the drainage-tube was inserted, and that healed a few days afterwards. When the patient left the hospital he could swallow without the slightest difficulty or discomfort.

Remarks.—The following remarks are based upon a careful perusal of the records of cases of diverticula of the pharynx and œsophagus reported in English.

The symptoms and signs in the case recorded above were so well marked that the patient and his friends had made the diagnosis. The regurgitation of food, which increased with compression of the neck, was the most prominent symptom, and occurred in all the recorded cases; in the early stages it was difficult to differentiate cases of diverticula from those of stricture. The radiograms were most valuable, more especially after the recurrence of the pouch.

Anatomically this case corresponds exactly with that series of ten cases of retro-cricoid diverticula of the pharynx collected from the London museums, and described by Professor Arthur Keith In his demonstration at the Royal College of Surgeons of England. The demonstration is reported, and the reader is referred to the excellent description and diagrams of the report.[1] Professor Keith showed that these diverticula were sacs composed of the mucous and submucous coats, which had become gradually evaginated between two definite parts of the inferior constrictor muscle, consisting of the upper part, which acts as a force-pump, and the lower part, which is sphincteric in nature.

The observations made at the time of the operations in the above case, with the examination and microscopy of the sac, correspond in every detail with Professor Keith's description. The case recorded above was a propulsion pouch which originated from, first, a weakness of the œsophageal wall; secondly, increased pressure within the œsophagus. It will be seen that it corresponds in pathology to a hernia through the abdominal wall.

With reference to the first factor—*weakness of the œsophageal wall*—Professor Keith has established the fact that there is a weakness in the position indicated above. Professor Halstead,[2] in a paper in which he discusses the cause of propulsion diverticula, refers to a weakness in the posterior wall of the œsophagus immediately below the inferior constrictor muscle.

The late Professor Birmingham[3] described a triangular interval in this position, which is formed by a separation of the longitudinal muscular fibres into two bands which diverge and pass upwards on the front of the œsophagus and are attached by a tendinous band to the upper part of the back of the cricoid cartilage. The triangular interval, which is about 1¼ in. in length and is formed by the diverging bands of longitudinal muscular fibres, is sometimes known as the Lannier Hackerman area. The narrowest part of the œsophagus and the circular fibres of the inferior constrictor, known as the cricoid constriction, are above this point. Halstead records in the same paper the case he treated by invagination of the sac, in which the neck of the sac was below the lower edge of the cricoid cartilage and the sac apparently became evaginated through the Lannier Hackerman area of the œsophageal wall.

Mr. William Robinson[4] in the report of a case in which he excised a diverticulum, states that he dissected the œsophagus of a woman, and could not find the deficiency of the longitudinal muscular fibres in the triangular interval described above, but Professor Birmingham has clearly demonstrated that the deficiency does exist. The pouch in Mr. Robinson's case was connected to the œsophagus at its extreme upper end.

Mr. Bilton Pollard[5] describes a similar case and definitely states that the diverticulum arose immediately below the inferior constrictor in the mid line and through the triangular interval. Mr. W. Taylor's[6] description of another case tends to support Mr. Bilton Pollard's conclusion as to the position of the opening of the diverticulum.

One of the authors (E. D. D.) dissected a few specimens of the œsophagus obtained from recent necropsies, and the triangular interval in the longitudinal muscular coat was not easily made out. When the dissected œsophagus was subjected to water pressure by attaching one end to the tap and securing the other there was a uniform dilatation of the œsophagus below and above the circular and sphincter portion of the inferior constrictor. The circular fibres of the constrictor appeared as a waist belt, and no weakness could be demonstrated on the wall of the œsophagus immediately below the inferior constrictor. Moreover, small incisions were made through the longitudinal muscular coat and prolonged water pressure applied, but neither sacculation nor dilatation occurred at the incisions, showing that the remaining portion of the wall of the gullet was strong enough to resist any protrusion of the mucosa.

Halstead also refers to cases recorded by Freiburg, and others in which the œsophageal wall was weakened by traumatism, the result of impaction of a foreign body or by rupture in cases of severe injury. In these cases the diverticula developed rapidly, and resulted in starvation and death.

With reference to the second factor in the cause of propulsion diverticula—*increased pressure* within the œsophagus—in a few cases there was a stricture, but in most neither stricture nor stenosis of the œsophagus was discovered. Professor Keith has drawn attention to the circular fibres forming the lower part of the inferior constrictor, which acts as a sphincter, and in the case recorded above this circular band was well developed, producing a possible functional stenosis below the pouch. In Professor Halstead's case it will be noted that this constriction was stated to be above the opening of the pouch, and this fact does not support his theory that diverticula evaginate through the Lannier Hackerman area. A similar condition appeared to have existed in Mr. Bilton Pollard's case, to which reference has been made.

Stenosis of the œsophagus has been known to produce dilatation of the tube above the point of stenosis. One of the late Sir H. T. Butlin's[7] cases (Case 6) was a wind instrument player, and the increased pressure produced in the œsophagus by such an occupation was considered to be a determining factor in the formation of the pouch he developed. Even a persistent severe cough is recorded as being a possible cause (Bilton Pollard).

The theory that these pouches are of congenital origin has been abandoned for several reasons.

The most successful treatment of diverticula of the pharynx is by operation. Richardson [8] states that of the 56 cases recorded before May, 1900, 18 were treated by operation, 16 of the 18 by excision, and 2 by the invagination method described by Girard.[9] Since 1900 Butlin has recorded 12 cases, in 8 of which the pouch was excised. Charles Mayo [10] recently records 8 cases; 6 were excised.

Halstead recorded one case of invagination, but in a recent private communication he states that he has had two more cases of diverticula. In one case the diverticulum was dissected out of its environs, and left intact outside the neck until the cavity occupied by the diverticulum had closed, and then at the second operation the diverticulum was removed, after the danger of mediastinal infection had passed. Unfortunately, the patient died from pneumonia. In the other case the diverticulum was successfully resected and the stump invaginated by sutures. W. Robinson, Bilton Pollard, and W. Taylor recorded three more cases treated by excision.

In the majority of the recorded cases of excision there was leakage of food into the neck, and the resulting risk of infection. For that reason Mr. Waggett decided to treat the above case by invagination. Of the two cases of invagination recorded by Girard one case was eminently successful, but in the second case a fistula resulted, and closed later.

Halstead describes his case of invagination more minutely, in which he put a purse-string suture around the neck of the sac and invaginated it, and covered the stump with three layers of sutures. The patient did well and made an uninterrupted recovery. Halstead states that invagination is only suitable for those cases in which the sac is small, and the lumen of the œsophagus is normal.

In some cases of emaciation and starvation a preliminary gastrostomy was performed, but it was unnecessary in our case. In one case, that of an old man, the patient was taught to empty the pouch by compression and to syringe it out with boric lotion after taking food, but he was ultimately operated on with success.

Recurrence of the pouch after excision appears to be rare. Butlin records that seven of his cases had no recurrence of the symptoms and that all of the seven patients were well. Mr. Bilton Pollard's case was quite well two years after the operation. An attempt to ascertain whether the three cases of invagination reported by Girard and Halstead had recurred was unsuccessful. No later information concerning cases of invagination could be obtained.

THE DIETETIC TREATMENT OF DIABETES.

BY P. J. CAMMIDGE, M.D. LOND.

ALL attempts at a specific or etiological treatment of diabetes have so far proved unsatisfactory, so that careful dieting is still the only reliable means we have of combating the condition. The more intimate knowledge, gained in recent years, of the chemical disturbances that are associated with glycosuria has placed the principles of its dietetic therapy on a much surer foundation, and permits of more accurate and scientific means being taken to adjust the food-supply to the metabolic powers of the body than was formerly the case. The aim of the modern treatment of diabetes is to balance the diet in such a way that nutrition is as perfect as possible without there being an unnecessary strain on the organs of metabolism in any direction.

It is now generally recognised that, while the administration of carbohydrates in larger amounts than the defective metabolic powers of the diabetic can deal with is injurious, their permanent exclusion from the diet is often not only unnecessary but positively harmful. A temporary exclusion is in some instances necessary and beneficial, for not only is the excess of sugar in the blood diminished so that the cause of many of the troubles to which diabetics are liable is lessened or abolished, but at the same time the metabolic powers, like a released spring, often recover their tone to a surprising extent, and the tolerance for carbohydrates is materially increased. Similar results are obtained in other cases by restricting the carbohydrates, both in quantity and kind, until the glycosuria is controlled.

Some diabetic patients have a marked susceptibility to proteins, which may yield 45, and in some instances 60, per cent. of sugar, so that their glycosuria is diminished more by restricting the protein intake, and allowing carbohydrates, than by excluding the latter altogether. The proteins of vegetables are, as a rule, found to be less harmful than those of meat, and consequently periods of vegetable feeding may be advantageously introduced into the treatment. For the same reason prepared vegetable proteins, soy beans, &c., may be made to replace meat to some extent in the ordinary diabetic diet.

No routine line of treatment, however sound it may be in principle, can be applied to all cases; the metabolic powers of each patient must be experimentally determined, and a diet adapted to his peculiarities and requirements be worked out—that is to say, we must treat the *patient*, not the *disease*.

Having discovered that a patient is passing sugar in his urine, the first point to settle is the gravity of the case. For this purpose we must ascertain: (1) the intensity of the diabetes; (2) the presence and degree of secondary abnormalities of metabolism; and (3) whether any disturbance of nitrogenous equilibrium exists. To this end the urine passed in 24 hours is collected, measured, the usual qualitative tests performed, and the total excretion of sugar, nitrogen, and ammonia nitrogen quantitatively determined.

1. In order that an accurate estimate may be formed of the power the patient possesses of dealing with sugar—that is, of the intensity of the diabetes—it is necessary that the intake, as well as the output, should be known. The latter is given by the urinary analysis; for the former the patient is put upon a diet of known composition, both as regards quantity and kind, for 48 hours before the urine is collected.

Since the amount of dextrose in the urine is dependent not only upon the quantity of ingested carbohydrate, but also upon the intensity of protein metabolism, the possible maximum of sugar that can be derived from broken-down protein must be included in the intake. According to Rubner, each gramme of protein nitrogen may correspond to 5 grammes of dextrose, so that if the total urinary nitrogen is multiplied by 5 the result will represent the sugar that may possibly be derived from protein, and this, plus the carbohydrate of the food, will represent the total sugar available for nutrition. If now the total output of sugar in the urine is divided by the total available sugar a figure is obtained that indicates the relationship between the two. Multiplied by 100 this figure gives the percentage of sugar eliminated unused, or Falta's "coefficient of excretion." [1]

On the ground that experiment has shown a constant dextrose to nitrogen ratio of 3·65 to 1 in the urines of dogs in which glycosuria has been produced by injections of phloridzin, after their glycogen store has been exhausted, and also in very severe human diabetes, when the patient was given a diet of meat and fat, Lusk [2] has suggested that the figures 3·65 should be substituted for 5 in determining the proportion of urinary sugar possibly derived from protein. This modified formula, which I now employ in my work, is stated as follows:—

$$\frac{\text{Total dextrose in the urine} \times 100}{(\text{Total urinary nitrogen} \times 3{\cdot}65) + \text{Food dextrose}} = \left\{\begin{array}{l}\text{Coefficient of}\\ \text{excretion.}\end{array}\right.$$

In collecting the urine for these analyses care should be taken that an early morning hour (before breakfast) terminates the 24 hour period. This is necessary, since the dextrose arising from the ingested proteid is eliminated before the corresponding nitrogen, and the long fast between the evening meal and breakfast allows of the excretion of both constituents. [3]

The coefficient of excretion may vary from 100 to 0, the former figure being obtained when there is total absence of tolerance for sugar, and the latter when carbohydrate intake and metabolism are balanced. It furnishes a definite numerical indicator of the severity of a diabetes in much

[1] Arch. Int. Med., 1909, p. 159.
[2] Journal of the American Medical Association, Dec. 17th, 1910, p. 2106.

the same way as a blood count and the hæmoglobinometer indicate the severity of an anæmia, or the thermometer shows the course of a fever. By determining the coefficient of excretion one case can be compared with another, and the progress of the same case can be judged from time to time more accurately than by the more commonly employed methods.

2. Of the secondary disturbances of metabolism that occur in diabetes, the most important is that associated with the imperfect oxidation of fats and proteins. The fatty acids contained in fats, and some of the oxy-acids formed in the breaking down of proteins, yield beta-oxybutyric acid if oxidation is incomplete. Thrown largely as it is upon its fat-burning powers to furnish the energy it needs, the diabetic organism may find that its capacity in this direction is also curtailed, with the result that beta-oxybutyric acid and its derivatives, aceto-acetic acid and acetone, are formed and excreted in the urine. The most serious result of the formation of these "acetone bodies" is the liability to diabetic coma. It is believed that they themselves are not toxic, but that they exert their poisonous effects in virtue of their acid properties; hence the condition in which they are present is spoken of as an "acidosis."

It is therefore important to detect the presence of these substances in the urine, and to estimate the degree of acidosis that exists. Unfortunately, there is no simple method for their quantitative determination, so that an indirect method of estimating the acidosis is very commonly employed. The index that is used is the amount of ammonia nitrogen that is excreted in 24 hours. Acids introduced into the blood are at first neutralised by sodium carbonate and other fixed bases, but when more acid enters the circulation than can be dealt with in this way a portion of the ammonia which normally goes to form urea is intercepted and combines with the acid, so that an increased amount of ammonia appears in the urine. The number of grammes of ammonia eliminated daily may be taken, therefore, as an approximate measure of the intensity of the acidosis. Normally from about 0·3 to about 1·0 grm. is excreted in the 24 hours, but in diabetes 2, 6, or even as much as 12 grm. may be passed. With an excretion of 3·0 grm. or over there is usually a danger of coma supervening.

3. The prognosis in cases that show signs of abnormal acid production is not, however, necessarily serious, for diabetics have been known to excrete 30 or 40 grm. of beta-oxybutyric acid daily and yet live comfortably for years.[4] According to Weintraud[5] acidosis is only dangerous when it is accompanied by a disturbance of nitrogenous equilibrium—that is to say, when more nitrogen is excreted than is being absorbed. For clinical purposes sufficiently accurate data for determining the nitrogenous balance are obtained by comparing the nitrogen-content of the food, estimated from diet tables, and allowing 1 grm. of nitrogen for each 6·25 grm. of protein, with the nitrogen excretion in the urine, plus 1 grm. to represent the unabsorbed nitrogen in the fæces, for a difference of one or two grammes a day is practically unimportant.

From the information obtained by these investigations there can be formed an accurate opinion as to the severity of the case, its prognosis, and the lines along which the treatment must be directed. It is advisable that the urine and fæces should, as a preliminary measure, be also examined for evidences of pancreatic disease, biliary affections, and intestinal trouble, so that means may be taken to deal with them if present, and thereby remove a possible source of metabolic disturbances which interfere with nutrition and may possibly be a factor in the production of the glycosuria.

When working out a diet for a diabetic it is important to bear in mind that he must be supplied with approximately 34 or 35 calories per kilogramme of his body weight, and that these must be contained in materials which experiment shows he can utilise. It is therefore necessary to ascertain, first, how much, and what kinds, of carbohydrate can be used with safety to supply the needful energy; secondly, what amount of protein is required to maintain nitrogenous equilibrium; and, thirdly, how much fat must be added to the diet to make up the balance of energy required. The answers to these problems can only be obtained by metabolic experiments, controlled by analyses of the urine and careful regular weighing of the patient.

The amount of carbohydrate that can be safely allowed is worked out by adding known quantities of various carbohydrates to a "carbohydrate-free" diet and watching the effect on the urine. If the patient has a low coefficient of excretion, the output of ammonia is not high, and nitrogenous equilibrium is well maintained—that is to say, it is a mild case—he should be put upon a diet containing about 3 oz. (85 grm.) of bread, which corresponds to about 47 grm. of added carbohydrate. If the urine is found to be free from sugar upon this, the daily amount of bread is gradually increased until glycosuria reappears. If, on the other hand, 3 oz. of bread are sufficient to cause sugar to appear in the urine, the amount is gradually reduced until either the glycosuria ceases or a "carbohydrate-free" diet is reached. In the former case, as in the first instance, the limit of tolerance for bread is that amount which just falls short of producing glycosuria.

In any case it is generally advisable to place the patient on a diet containing no added carbohydrate for a week or two, when his tolerance is again tested. In most cases it will be found to have increased, and may in some instances approach the normal. It is now tested for other forms of carbohydrate by adding weighed quantities of these to the "carbohydrate-free" diet on separate days. Finally, a mixed diet containing a little less carbohydrate than has been found to be the toleration limit, and calculated to yield the requisite number of calories, is worked out from these data. It will be generally found that some sources of sugar are better borne than others, and by selecting several of those that appear to be most suited to the idiosyncrasies of the case considerable variety can be given to the diet, a most important consideration from the patient's point of view. Every two or three months the collected 24 hours' urine should be re-examined and the diet changed according to the metabolic findings.

The procedure with severe cases, where the coefficient of excretion is high and there are well-marked secondary disturbances of metabolism, is necessarily different, for we have here not only to consider defective carbohydrate utilisation, but also the deficient powers of dealing with proteins and fats. The first thing to do is to restore the nitrogen balance as much as possible. As a preliminary step the sugar in the urine must be reduced to the lowest limit consistent with safety, since diuresis is thereby diminished, and nitrogenous equilibrium is impossible with an excretion of more than 1200 or 1500 c.c. of urine a day. It is usually unwise to attempt to remove all starchy foods from the diet and to render the urine sugar-free. Most patients will be found to do better when one variety is given alone than when several are taken together, and some kinds will generally prove to be more suitable than others, hence the introduction of the so-called oatmeal, potato, and rice "cures" for diabetes. The next step is to reduce the nitrogenous food until only 100, 80, or even 60 grm. of protein are being taken in the day and not more than 12 or 15 grm. of nitrogen are appearing in the urine. Rest in bed and small doses of codeia or opium are useful aids in obtaining nitrogenous equilibrium. Vegetable proteins and eggs may be substituted with advantage for an equivalent amount of meat, especially when there is marked and persistent acidosis. Periods of entirely vegetable and egg diet at intervals are also useful in controlling this condition.

The balance of the dietary must be made up with fat, for although the acetone bodies are chiefly derived from fat, very large additions to the diet are necessary to appreciably influence their output. Since the lower fatty acids are more prone to induce acidosis than the higher, substances containing them, such as unwashed butter, should be avoided. A diabetic with no tolerance for carbohydrate will require from 200 to 300 grm. of fat a day, according to his weight, but in order that such a large amount may be consumed all the resources of the kitchen and the art of the physician will be severely taxed to present it in an appetising and assimilable form. Spirits and dry wines are of distinct value in preventing the digestive disturbances that a richly fatty diet is liable to cause, but the total alcohol-content of these should not exceed about 40 grm. a day.

The experimental data obtained in the course of the investigation of a case of glycosuria, or other disorder of metabolism, are most conveniently collected together in the

[4] V. Noorden: v. Leyden's Handbuch der Ernährungstherapie, 1904, ii., p. 253.

[5] Therapeutische Monatschrift, December, 1908.

form of a chart, prepared by plotting out the results on squared graph paper. In this way the bearings of the urinary analyses on the diet, and the relations of one analysis to another, are much more readily and clearly appreciated than when the figures alone are studied. The specimen charts Nos. 1 and 2 indicate the way in which the method is employed, but for the sake of clearness all the data have not been inserted, as this necessitates the use of coloured inks.

CASE 1.—The patient was sent to me by Dr. J. Brunton Blaikie. The case was a serious one with a coefficient of excretion of 84 per cent., and an ammonia nitrogen excretion of 1·2 grm. in the 24 hours, on a diet containing 76 grm. of carbohydrate, including 3 oz. of bread. On reducing the bread to 2 oz. the coefficient of excretion fell to 66 per cent., but even with no added bread and a diet containing only 20 grm. of carbohydrate, it stood at 65 per cent., and the ammonia nitrogen rose to 1·8 grm. in the 24 hours. By cutting down the proteins of the diet the coefficient of excretion was reduced to 62 per cent., and the ammonia nitrogen excretion dropped to 1·5 grm. His tolerance for different forms of carbohydrate was tested by adding dextrose (25 grm.), levulose (25 grm.), milk (1 pint), oatmeal (3½ oz.), potato (3½ oz.), and apple (5 oz.) successively to the test diet, with the results shown in the chart. From these it is apparent that both pure dextrose and pure levulose were utilised with difficulty, but that the carbohydrates contained in oatmeal and potato were metabolised comparatively well. The addition of milk, oatmeal, and potato was found to be followed by a reduction in the output of ammonia nitrogen, so that they apparently diminished the acidosis. A diet based upon these results was worked out and taught to the patient. At the end of his stay in the nursing home he was put upon a diet containing 24 grm. of carbohydrate, and it was found that his coefficient of excretion had fallen to 55 per cent., as compared with 65 per cent. when the treatment was commenced, so that his power of dealing with carbohydrate had improved by about 10 per cent.

CASE 2.—Chart 2 illustrates the results obtained with a less severe case, sent to me by Dr. L. Vernon-Jones. In this instance restricting the carbohydrate was followed by a marked diminution in the percentage of food sugar passed unused in the urine, and by a progressive decrease in the excretion of ammonia nitrogen, whereas in the former case it caused a rise in the ammonia nitrogen and only a comparatively slight decrease in the coefficient of excretion. With a diet containing 85 grm. of carbohydrate, including 3 oz. of bread, the coefficient of excretion worked out at 43 per cent., with an ammonia output of 0·87 grm. in the 24 hours. The same diet with 2 oz. of bread gave a coefficient of excretion of 24 per cent. and an ammonia output of 0·68 grm. On a test diet containing 23 grm. of carbohydrate a coefficient of 20 per cent. and an ammonia nitrogen of 0·57 grm. were obtained. In this case there was no serious interference with nitrogenous equilibrium, so that it was neither necessary nor advisable to reduce the protein content of the food. On testing his carbohydrate tolerance with dextrose (50 grm.), levulose (50 grm.), milk (1 pint), oatmeal (3½ oz.), and potato (3½ oz.), it was found that levulose was more readily metabolised than dextrose, and that 1 pint of milk, 3½ oz. of oatmeal, 3½ oz. of potato, and 2 oz. of bread gave approximately the same coefficient of excretion. His diet was therefore worked out on this basis. A test diet containing 24 grm. of carbohydrate given at the end of the investigations showed a coefficient of excretion of 11 per cent., as compared with 20 per cent. at the beginning, and an ammonia nitrogen excretion of 0·55 grm.

In the treatment of diabetes everything depends upon systematic dietetic measures being instituted at as early a stage as possible, for the whole future of the case depends upon its management at this period. It is exceedingly important that the diet should be prescribed quantitatively, as well as qualitatively, and this is true, not only of the well-marked cases, but also of the mild forms, and even of transient glycosuria, which, if neglected, may pass later into typical progressive diabetes. To merely give a patient lists of foods that he may take, and must avoid, is less than half the battle. What he needs to be taught is how much of each permitted food he may, and must, take to keep up the supply of energy he requires. At first all his food must be weighed, but it is remarkable how quickly the eye can be trained to accurately estimate weights and measures, and after a time only an occasional appeal to the balance is necessary. One useful purpose that the preliminary experimental investigations serve is to provide an opportunity for such education, since observations of this nature can only be satisfactorily carried out in a nursing home or hospital, where the food is prepared under strict supervision, and both it and the excreta are accurately weighed and measured.

Nottingham-place, W.

THE IMMEDIATE RESULTS OF SANATORIUM TREATMENT

CONTRASTED WITH THE RESULTS OBTAINED BY A COMBINED SANATORIUM AND TUBERCULIN TREATMENT.

BY J. A. D. RADCLIFFE, M.B. R.U.I.,
PATHOLOGIST, KING EDWARD VII. SANATORIUM, MIDHURST.

WHILST the final judgment as to the value of any form of treatment in pulmonary tuberculosis must rest on the ultimate results, as shown by the after-histories of the cases, still some information can be obtained by an examination of the immediate effects. The most important result is the disappearance of the tubercle bacilli from the sputum, for if the treatment has effected this the patient has ceased to be a potential source of infection for those with whom he is brought into contact.

It has now been conclusively proved that practically all cases of pulmonary phthisis are due to infection with the human type of bacillus. Kossel[1] in a recent analysis gives the following figures: Number of cases investigated, 709; of these, 705 are human, 2 are certainly bovine, 1 due to a mixture of human and bovine, and 1 doubtful). Consequently, the serious source of infection is the patient with tubercle bacilli in his sputum. Any form of treatment, therefore, which can largely reduce the percentage of such cases is the one to be preferred, particularly from the public health standpoint.

At the present time the chief methods of treatment in pulmonary tuberculosis are: (1) the sanatorium, with or without graduated labour; and (2) tuberculin, either alone or preferably combined with the sanatorium.

It is of interest to compare the immediate results given by these two methods, taking as a standard for comparison the presence or absence of tubercle bacilli in the sputum at the termination of the treatment. For this purpose I have compared the results obtained in the King Edward VII. Sanatorium, without tuberculin, with those of some of the foremost sanatoriums in Germany, where tuberculin has established itself as an essential part of the treatment.

1. *Sanatorium Treatment Alone.*

The cases coming under this heading are all those admitted here during the past four years who fulfil the following conditions: (*a*) Have tubercle bacilli present in the sputum on admission; (*b*) remain a minimum period of 12 weeks under treatment. This latter condition excludes a fair number of severe and advanced cases who are admitted for one month "on probation," and whom it would not be correct to include as having undergone the open-air cure. Twelve weeks have been arbitrarily fixed as the lowest time admissible. During the four years under consideration 631 patients have been admitted who fulfilled the two conditions, and the immediate results are shown in Table I.

TABLE I.

Classification according to Turban-Gerhardt.	Total number of patients.	Number of patients who lost their tubercle bacilli.	Number expressed as a percentage.	Average stay in sanatorium in weeks.	Minimum stay in weeks.	Maximum stay in weeks.
Group I.	160	73	45·62%	20·16	12	46
„ II.	315	60	19·04%	21·82	12	63
„ III.	156	14	8·97%	21·03	12	61
Totals	631	147 =	23·3 %	—	—	—

The above table shows that of 631 patients, 147, or 23·3 per cent., lost their tubercle bacilli whilst under treatment in the sanatorium; and it also brings out very clearly the advantages of treatment (of the cases) before physical signs are well marked, for in Groups I. and III., which are almost equal in numbers, the percentages of those who became free from bacilli are 45·62 and 8·97 respectively—that is, the results in Group I. are more than five times as good as in Group III.

These figures are, on the whole, better than those obtained under similar conditions in Germany; as Loewenstein[2] states that the reports of the public sanatoriums (Volkheilstätten), which have paid special attention to this point, give a percentage of from 12 to 25 of the cases in whom sanatorium treatment alone has led to a disappearance of the bacilli from the sputum.

2. *Combined Tuberculin and Sanatorium Treatment.*

For this part I have taken the results published by some of the foremost of the German sanatoriums, which deal with large numbers of patients. First, Loewenstein[3] reports on the year 1909 in the *Heilstätte Beelitz der Landes-Invalidenversicherung*, Berlin. In his figures he includes all those who during treatment reached a state of immunity towards either 10 mg. of old tuberculin or 0·01 mg. of new tuberculin. His patients are only considered free from bacilli when the sputum has been examined with negative result on four occasions, using the antiformin method and always after an injection of tuberculin. This is a much more severe test than that to which our patients are submitted, and consequently makes his figures of very great value in estimating the effect of tuberculin treatment. He reports on 682 cases with tubercle bacilli present, who reached the state of immunity mentioned, and classifies them according to the variety of tuberculin with which they have been treated. His results are given in Table II.:—

TABLE II.

Treatment.	Total number of patients.	Number of patients who lost their bacilli.	Number expressed in percentages.
Old tuberculin	409	237	57·94
New tuberculin	204	86	42·15
Old and new tuberculin	69	38	55·07
Totals	682	361	= 52·93

Special importance is laid on the last group, in which both preparations were used, as these were severe cases belonging to the second and third stages. It is also pointed out that the results would have been even better if a higher state of immunity had been taken as the minimum, as it is only in a few cases that the "cure" is finished when 10 mg. has been reached. This amount was chosen because it is the maximum dose used in diagnosis.

Secondly, Bandelier[4] reports on 202 cases, with tubercle bacilli present in the sputum, who were submitted to the combined treatment, with the following excellent results:—

TABLE III.

Group.	No. of patients.	No. of patients who lost their bacilli.	No. expressed in percentages.
I.	10	10	100·0
II.	79	69	87·3
III.	113	50	44·2

Thirdly, Curschmann, of the Heilstätte der Badischen Landesversicherungsanstalt, is quoted by Bandelier and Roepke,[5] and gives the following results after a three months' combined treatment:—

TABLE IV.

Group I.	80% ...	Sputum negative at the end of the "cure."
„ II.	47·7% ...	„ „ „ „ „ „
„ III.	33·75% ...	„ „ „ „ „ „

In this table the numbers belonging to each group are not

stated, but they are included as showing what can be accomplished by a three months' treatment. In the sanatoriums referred to tuberculin is given in small doses, gradually increasing in amount until very large quantities are tolerated, but avoiding as far as possible any severe reaction during the treatment. Reactions are even less likely to occur if the albumose-free tuberculin introduced by Koch be substituted for the old tuberculin. This can be followed, if necessary, by a course either of old tuberculin or, perhaps even better, by bacilli emulsion.

Summary.

1. With sanatorium treatment alone we can only reckon on 20 to 25 per cent. of all cases losing their bacilli as an immediate result of the treatment.
2. When a combination of tuberculin with sanatorium treatment is adopted, at least 50 per cent. of the cases will lose their tubercle bacilli.
3. The earlier the cases come under treatment the better the results. This is very strikingly shown in the tables in which the cases are considered in groups according to the stage of the disease.
4. A comparison of the immediate results is so much in favour of tuberculin that it is difficult to understand the opposition to its employment, both in treatment and diagnosis.

In conclusion, I wish to express my thanks to the consulting staff of the King Edward VII. Sanatorium for permission to publish this paper.

Midhurst.

ACUTE INTESTINAL OBSTRUCTION

CAUSED BY THE APPENDIX VERMIFORMIS, THE OBSTRUCTION OBSCURING AN ACUTE APPENDICITIS.

BY E. GILLESPIE, M.B. GLASG., F.R.C.S. ENG.,
ASSISTANT SURGEON, PRINCE OF WALES'S HOSPITAL, N.

THE following case illustrates an unusual combination of circumstances.

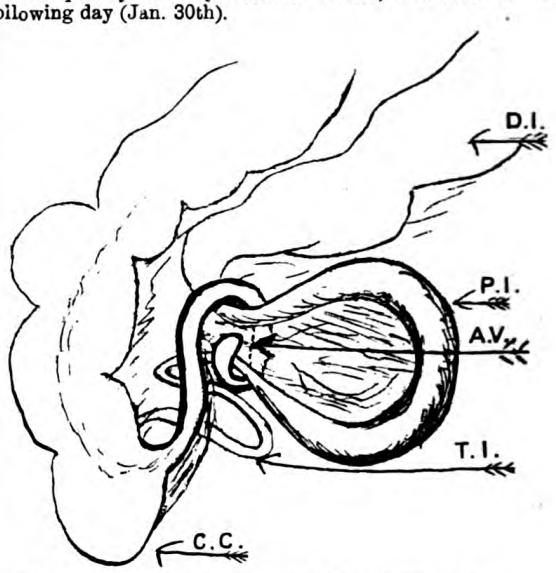
The patient, a male, aged 10, was admitted to the Prince of Wales's Hospital on Jan. 29th, 1912. The boy had always enjoyed good health. On Jan. 23rd he complained of abdominal pain localised round the umbilicus. He also vomited. The pain and the vomiting continued until admission, the latter becoming more frequent. The bowels were opened on the 24th, after an enema, but not since. On the 28th the condition was worse, and distension of the abdomen was noticed. The patient was admitted to hospital on the 29th.

Examination on admission.—The patient looked very ill. The face was cyanosed; the tongue furred and dry. Temperature 97° F., pulse 100, respiration 28. Before operation the patient had fæcal vomiting. The chest showed nothing abnormal. The abdomen was distended. Coils of intestine could be seen showing through the abdominal wall, and giving the step-ladder appearance of small intestine obstruction. The abdomen felt tense, but had not the rigidity of an inflammatory lesion. There was no localised tenderness on palpation. The movements with respiration were deficient. The percussion note all over was resonant. Rectal examination revealed a distended empty rectum; nothing abnormal was felt in the pelvis.

Operation (Jan. 29th).—Under general anæsthesia with open ether the abdomen was opened by the para-umbilical incision to the right of the middle line. Coils of distended and congested small intestine at once showed. On introduction the examining hand could feel a loop of intestine tightly constricted by a band. The portion of intestine was isolated and brought to the surface. The strangled loop was found to be about 18 inches of the ileum close to its lower end. The band was also a piece of intestine, stretched, and thinned out. Further search showed that it was the appendix vermiformis. It had encircled the loop, passing at first over and in front of it, then downwards behind. Finally, the tip appeared round the lower border and gained an attachment in front to the mesentery close to its junction with the gut. (See figure.) In addition the loop of intestine was rotated through about 90° from right to left of the patient on an axis lying in the length of the mesentery and at right angles to the intestine. It may be noted that this rotation was in the same direction as the appendix encircled the gut.

The appendix was freed and found to have a recent perforation close to the tip. The perforation had been sealed for the time being by the attachment to the mesentery. Appendectomy was performed. The intestine, which was quite viable, was returned into the abdomen. The incision was closed by a single layer of through-and-through sutures.

Subsequently the boy became weaker, and died on the following day (Jan. 30th).



Diagrammatic view of condition. D.I., Distended ileum above. P.I., Paralysed loop of ileum. A.V., Tip of appendix vermiformis attached to mesentery. T.I., Collapsed terminal portion of ileum. C.C., Caput cæci. The rotation is not indicated in the diagram.

Remarks.—1. Obstruction due to a Meckel's diverticulum in the above situation is well recognised. But a similar lesion caused by the appendix would seem to be much more rare. Treves quotes some cases in his "Intestinal Obstruction" in which the appendix after its tip had acquired a secondary attachment was the means of causing obstruction. In the case reported, however, the appendix was in an acutely inflamed state.

2. The position taken up by the appendix was a most unusual one. It is difficult to picture the sequence of events. To judge from the ease with which the appendix was separated the obstructing position must have been a recent one.

3. The complete obscuration of the signs of the appendicitis. The condition on examination pointed to an obstruction caused by a band or to kinking due to adhesion over a breaking down gland in the mesentery. Such, indeed, was the provisional diagnosis.

Harley-street, W.

ROYAL FREE HOSPITAL.—Sir Edward Durning Lawrence presided on March 13th at the Eighty-fourth Annual Court of Governors of this hospital. The report of the committee of management stated that the financial position of the hospital had been satisfactory. The statistical returns showed that the average cost per in-patient per week during 1911 amounted to £1 17*s.* 5½*d.*, against £1 14*s.* 3*d.* in 1910; the cost per out-patient attendance amounted to 11$\frac{1}{16}$*d.*, compared with 10¼*d.* during the previous year. The total number of patients under treatment in the wards and out-patient departments during the year was 35,596 There were 2204 in-patients admitted, in addition to the 140 who were in the wards at the beginning of the year, thus making a total of 2344 in-patients for the year. The average stay of patients in the wards was 23 days. Reference was made by the chairman to the conclusion of negotiations for the acquisition of a large area of land in the rear of the hospital upon which a new out-patient department would soon be erected.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Pancreatic Calculus removed by Operation.—Multiple Growths of the Great Gut.—Hydrocephalus Internus; Rupture into the Subdural Space; Intracranial Tension and its Temporary Relief.—Multiple Fibromata of the Tunica Vaginalis.

A MEETING of this section was held on March 12th, Mr. CLINTON T. DENT, the President, being in the chair.

Mr. JOHN MURRAY read a paper on a case of Pancreatic Calculus, in which the stone had been removed by operation. The patient was a female, aged 40, who had suffered from attacks of pain in the epigastrium since 1888. The attacks came on immediately after food and usually lasted about two hours. There was no vomiting at first. These symptoms continued for seven or eight years, when the attacks became less frequent, and for a period of two years she was free from pain. Ten years ago she had a severe attack which lasted 18 hours and was followed by jaundice. In 1905 she suffered from occasional slight colic. In 1906 an attack was accompanied by vomiting, epigastric tenderness, and cardiac irregularity. On July 23rd, 1910, she had severe pain and frequent vomiting, and on the following day became jaundiced. The jaundice continued until the middle of September, when the gall-bladder could be distinctly felt to be enlarged. On Sept. 24th the abdomen was opened through the right rectus muscle. The gall-bladder was aspirated and several ounces of bile withdrawn. There were no stones in the gall-bladder, but a stone could be felt apparently lodged in the common bile-duct. It was found to be necessary to enlarge the incision in the abdominal wall, and after this had been done a prolonged and careful search failed to discover the position of the stone. The abdominal wound was therefore sutured, a drain-tube being placed in the gall-bladder. The wound healed, and the patient returned home, but on the same day she was seized with pain and vomiting, and soon became jaundiced, the attack lasting 22 hours. The gall-bladder became distended, and subsequently the scar broke down and a large quantity of bile escaped. On Nov. 7th the abdomen was reopened, when the stone was at once found occupying its original position, lying behind the second part of the duodenum. The peritoneum was divided on the outer side of the duodenum, which was then displaced towards the left side, and after tearing through some pancreatic tissue the pancreatic duct was exposed. This was incised and the stone extracted. The duct was sutured and the abdominal wound closed, two drainage-tubes being introduced, one into the gall-bladder and the other towards the outer edge of the duodenum. The patient made an uninterrupted recovery, and had had no further trouble.—The paper was discussed by Dr. P. J. CAMMIDGE and Mr. H. BETHAM ROBINSON.

Mr. G. H. MAKINS, Mr. CUTHBERT S. WALLACE, and Mr. PERCY W. G. SARGENT communicated a paper on Multiple Growths of the Great Gut. The authors thought that as the following cases had occurred in their practice in a comparatively short time it was probable that they were more frequent than the text-books would lead one to suspect. They seemed to offer some food for reflection, both from a clinical and pathological point of view. 1. Male, aged 39. Two ring carcinomata, separated by an interval of about 6 inches, were present in the parts removed from the transverse colon in 1905. A second ring carcinoma was removed from the junction of the iliac and pelvic colons in 1908. It was probably present in 1905. In May, 1911, an ulcerating ring carcinoma was removed from the transverse colon immediately above the scar of the first resection. No other growths could be felt anywhere in the abdomen; no enlarged glands could be detected; the liver was not enlarged, and the whole of its accessible surface felt uniformly smooth. 2. Female, aged 53. A ring carcinoma occurred at the middle of the sigmoid loop, and another ring carcinoma in the rectum at the level of the os uteri. The bowel was hypertrophied above the highest growth and between the two. The upper growth was microscopically a columnar carcinoma. 3. Male, aged 56. The whole large intestine was beset with polypi. There were also an ulcerating ring carcinoma 12 inches from the cæcum and a second similar carcinoma 8 inches below the first. 4. Female, aged 43. There were two growths—a contracting ring carcinoma of the splenic flexure and an ulcerating carcinoma within 4 inches of the anus. A non-ulcerative polypoid condition of the mucosa extended from the upper growth to the anus. The muscle coat of the bowel was hypertrophied above the splenic growth, but not to any appreciable extent below it. 5. Female, aged 66. There were a ring carcinoma of the ascending colon with secondary glands and many polypoid growths on the distal side of the carcinoma. No microscopic examination was made. 6. Male, aged 32. A ring carcinoma occurred at the junction of the pelvic and iliac colons. Many minute polypi were found above the growth (extent upwards unknown), and multiple masses of simple polypi and carcinomatous ulcers below it. The annular growth was a columnar carcinoma, whilst one of the polypoid masses was a simple adenoma. 7. Female, aged 34. A ring carcinoma at the beginning of the ascending colon was accompanied by infected glands. From this growth down to the hepatic flexure polypi occurred scattered over the mucous membrane at gradually increasing intervals. The ring carcinoma and the polypi were shown to be columnar-celled carcinomata. 8. Female, aged 51. A ring carcinoma of the splenic and of the transverse colon was present. Immediately proximal to it was a pedunculated adenoma, which had been impacted in the ring growth. Microscopically the ring growth was a carcinoma, the pedunculated tumour an adenoma. The cases seemed to fall into four classes. 1. Ring carcinomata with a length of normal bowel between them (Cases 1 and 2). 2. Ring carcinomata having the mucous membrane between them covered with simple polypi (Cases 3 and 4). 3. Ring carcinoma having the mucous membrane distal to it covered with (1) simple polypi (Case 5); (2) simple and malignant polypi (Case 6); (3) malignant polypi (Case 7); and (4) ring carcinoma having a simple polypus immediately proximal to it. It was a question as to what relation these various growths bore to one another. If one was secondary to the other, what was the method of dissemination? Lymphatic infection, permeation, and peritoneal dissemination seemed to be excluded. The lower growths would then be either primary tumours or infection tumours. The cases in which the mucous membrane below the growths was the seat of polypi suggested that the ring carcinomata might have produced some exudate which irritated the mucous membrane to produce benign growths which in their turn became malignant. It would of course be possible to suggest that the polypi were first formed and later underwent a malignant transformation into ring carcinomata and malignant polypi. Clinically the multiplicity and chronicity of the growths was the striking feature.—The paper was discussed by Mr. C. GORDON WATSON, Mr. BETHAM ROBINSON, and Mr. CHARTERS J. SYMONDS.

Mr. W. G. SPENCER read a paper entitled "Hydrocephalus Internus; Rupture into the Subdural Space; Intracranial Tension and its Temporary Relief." It was based on the following case. A boy, aged 5 weeks, was admitted, apparently suffering from hydrocephalus internus, who exhibited marked intracranial tension, rigidity, frequent vomiting, and screaming fits. With the object of making a communication between the cerebral ventricles and the subdural space the skull was trephined, when all the fluid was found in the subdural space. In order to afford an escape for the fluid several attempts were made to drain it into the subcutaneous tissue. Finally, a communication with the nose through the ethmoid plate was set up in order to produce the condition causing cerebro-spinal rhinorrhœa, such as has followed accidents, &c. This gave relief from tension until the child's death some time later, when it was found that the cerebral ventricles had ruptured into the subdural space, so that the membranous sac representing the cortex had quite collapsed. Finally, a comparison was made between the results obtained by Goltz from removing the cortex of the cerebral hemispheres in dogs and that which could be observed in the child.

Mr. MAKINS read a short paper on a case of Multiple Fibromata of the Tunica Vaginalis. The patient, a man aged 27, had noticed some nodules at the back of the right testis as long as he could remember. These had given rise to no inconvenience, but of late they had been increasing in size

and number. Examination revealed a group of nodules like a bunch of grapes in the back part of the scrotum. The skin was free, but the nodules were attached to the back of the testis. With this exception the testicular outline was perfect and the organ apparently normal in size and consistence. The growths were removed. They were situated beneath the serous layer of the tunica vaginalis, a large group over the centre of the epididymis and two small nodules on the outer surface of the body of the testis. No definite connexion existed between the separate nodules, and the whole were readily removed by dissecting away the tunica vaginalis. Only one similar case appeared to have been recorded, that by Tikhanovitch, quoted by Balloch in the *Annals of Surgery*, vol. i., 1904, p. 396. All other recorded instances had been of large soft fibromata showing often a tendency to central necrosis. Removal was indicated, since the tumours generally had shown a tendency to enlarge indefinitely and to necrose. In the case recorded the peculiarity consisted in the arrangement in multiple discrete nodules, and the hard character of the fibrous tissue forming the tumour. In nature the nodules were probably identical with the small fibromata occasionally met with in the subserous layer of the parietal and visceral peritoneum.

SECTION OF ANÆSTHETICS.

Ether and Hedonal Infusion Anæsthesia.

A meeting of this section was held at 15, Cavendish-square on March 1st, Dr. W. J. MCCARDIE, the President, being in the chair.

Dr. F. S. ROOD read a paper on Ether Infusion Anæsthesia. After quoting the results and describing the methods of ether infusion anæsthesia in various continental clinics, he proceeded to describe his modification of the apparatus. He commenced at first to employ a solution of 10 per cent. ether in normal saline solution, but finding that there was some hæmolysis as a result he next employed a 5 per cent. solution. Finding that the induction of anæsthesia was apt to be longer than convenient, and that the quantity of fluid injected was open to the objection of being unnecessarily large, he next used a 7·5 per cent. solution. This gave perfect results. There was no hæmolysis and the induction period was now reduced to a few minutes. The patient was given a hypodermic injection of morphia 1/6th gr., scopolamine 1/100th gr., and atropine 1/100th gr., about three-quarters of an hour before operation. The median cephalic or median basilic vein in the arm was exposed under local anæsthesia (produced with β-eucaine solution) and the cannula tied in. It was found that it was an advantage to close the wound so produced at once, leaving one stitch untied until the end of the operative procedure of the surgeon. Of course, any vein—e.g., the saphenous in the leg—could be used. The solution was warmed by being passed through a specially devised warming chamber before being allowed to enter the vein. At first the fluid was run in with the tap turned full on, and anæsthesia should be induced by running in from half to one pint of the 7·5 per cent. ether saline solution in from three to five minutes. After the induction of anæsthesia the tap which regulated the flow was so turned that a succession of drops was run into the vein practically continuously. This obviated any possibility of clotting and reduced the quantity of fluid injected to the minimum necessary to maintain anæsthesia. Respiration should be carefully watched and depth of anæsthesia carefully regulated by increasing or decreasing the rate of flow. Anæsthesia was so quickly lightened or deepened that the anæsthetist needed to pay great attention to the rate of flow employed. He had now employed this method in 136 cases and had practically no bad after-results; 6 patients only vomited, 3 of whom had swallowed blood.

Mr. C. M. PAGE next read a paper on Hedonal Infusion Anæsthesia. The method had been first introduced in 1910 by Federoff, of St. Petersburg. He reported 530 cases from several Russian clinics; in no instance was death attributable to the anæsthetic. The method adopted was one of *interrupted* infusion. Mr. Page reported on 75 cases in which he had used hedonal at St. Thomas's Hospital. The drug was infused *continuously* from a special tank and a 0·75 per cent. solution of hedonal in normal saline solution was employed. In all instances good anæsthesia was obtained. The largest amount of solution infused in any one case was 2000 c.c., the smallest was 40 c.c. The anæsthesia obtained was steady and associated with great muscular relaxation. The patient usually remained sleeping for from six to eight hours after the operation was finished. The only danger likely to arise during the anæsthesia was cyanosis, either from obstruction to the air passages or from a too rapid dosage. The solution should be allowed to run in at the commencement at a rate of 50 to 100 c.c. per minute.—Mr. L. E. BARRINGTON-WARD reported the first case of death during hedonal anæsthesia in this country. The patient was a girl aged 8, of fair size and development, and so far as could be determined quite normal, except for tuberculous glands in the neck and enlarged tonsils. The method used was that described by Mr. Page, to whom he was indebted for letting him see some cases of hedonal infusion anæsthesia. The injection was normal, the left saphenous vein being selected. The operation was started 10 minutes after the commencement of anæsthetisation, and at that time 300 c.c. of a 0·75 per cent. hedonal solution had been used. The child was of a good colour and not at all deeply under. After another 20 minutes the skin stitches were being put in when without any warning the patient stopped breathing. The colour remained good and there was no respiratory obstruction whatever. Efforts at resuscitation were made by artificial respiration, bleeding, injection of strychnine, atropine and ether, and massage of the heart through the abdomen, but, unfortunately, without success, though they were persisted in for 1½ hours. During the actual period of operative procedure another 200 c.c. of the 0·75 per cent. hedonal solution had been used, making a total of 500 c.c. used from the commencement of the administration until the respirations failed. Post mortem there was an enlargement of lymphoid tissue generally all over the body. The thymus was distinctly enlarged, and it enwrapped the great vessels at the base of the heart in a curious manner. The Malpighian corpuscles were especially prominent, the glands in the abdomen were hypertrophied, and there was a mass of lymphoid tissue about the ileum and cæcum. The tonsils were enlarged and there was a greatly hypertrophied ring of lymphoid tissue around the tonsil, tongue, and pharynx. The heart was not abnormal in colour, but it was dilated, and on subsequent microscopical examination exhibited fatty degeneration. The bases of the lungs were œdematous, and there was an excess of free fluid in the pericardium. Dr. B. H. Spilsbury, who performed the post-mortem examination at the request of the coroner, considered the case to be one of status lymphaticus. The dose in this case was not excessive for the age and weight of the patient. Mr. Barrington-Ward said that he did not propose to say more about the hedonal infusion method as his experience amounted to 20 to 30 cases at the Children's Hospital, Great Ormond-street, and that was too few to dogmatise from. He had had no trouble or anxiety in any of the other cases in which he had employed the method. He would be glad to answer any questions.—The PRESIDENT said the section was fortunate in having so much recent good work brought before it at one sitting, and both Dr. Rood and Mr. Page could be congratulated on the number of their cases, their results, and the improvement in technique they had effected. They were also indebted to Mr. Barrington-Ward for the clear account he had given of a fatal case under hedonal. He only wished equally good reports of all fatalities during anæsthesia were furnished, then more would be learned about the causes of such fatalities.—In the subsequent discussion Mr. G. A. BARTON said he was glad to see that infusion anæsthesia had been given a trial in this country. Two years ago he had expressed the hope that it would be. However, he did not think the method offered, in ordinary cases, better results than did scopolamine, morphia, and open ether. He thought all the advantages claimed by Dr. Rood for the infusion method were obtainable by inhalation. There were, of course, occasions when infusions would be useful. He thought the present apparatus should be simplified. Possibly some apparatus like that invented by Dr. Maguire for his formalin injections would be possible.—Dr. HAROLD LOW discussed the question of safety and the advantages and disadvantages of the infusion method, more especially with reference to hedonal. The anæsthesia obtained under hedonal was perfect. It was easily induced and maintained, respiration undisturbed, muscles completely relaxed, no after vomiting; the patient slept after operation during the time that pain was most likely to be felt. He did not think that either of

the methods discussed that night would take a place as the routine method, but they would rather take their special place for suitable cases.—Dr. J. F. W. SILK pointed out the not uncommon difficulty in finding the vein, on the importance of the anæsthetist being at the head of the patient, and on the danger of a possible clot being washed into the circulation. He thought the method would find its level, more especially for cases that needed transfusing for possibly-shock-producing operative procedures.—Mrs. DICKINSON BERRY asked Mr. Page what he considered were the advantages of hedonal over ether infusion as a method of anæsthesia.—Dr. J. BLUMFELD dwelt on the length of time the induction of anæsthesia took in ether-infusion when 5 per cent. solution was used, and advocated a stronger solution.—The PRESIDENT thought that in these new methods anæsthetists possessed an addition to their armamentarium which might be useful in selected cases for operations on the upper part of the body, just as spinal anæsthesia was especially applicable in certain cases in the lower half of the body.—In his reply, Dr. ROOD dwelt on the absence of after-sickness and bronchitis. He emphasised the necessity for strict asepsis. The largest amount of fluid he had ever had to use was between 4 and 5 pints. With regard to the rate of injection, he turned the tap full on at first. From 12 to 18 ounces would be necessary for a healthy adult male, and the period of induction averaged four minutes. For weakly people half that quantity would be necessary.—Mr. PAGE, replying, thought that there were less cyanosis and congestion in the air-passages with hedonal than with inhalational anæsthesia. With regard to the advantages of hedonal over ether infusion, he thought the apparatus was simpler; being composed of metal it was unbreakable and more capable of sterilisation. The solution could be boiled and remained stable. This latter advantage enabled the anæsthetist to run in his solution at a higher temperature than was possible with the ether method. Hedonal was said to be less irritating to the tissues than ether, and as it was excreted by the kidneys there was no irritation of the lungs. Being but slowly excreted less fluid had to be injected to maintain anæsthesia.

OTOLOGICAL SECTION.

The Value and Significance of Hearing Tests.

A MEETING of this section took place on March 15th at Chandos-street, Cavendish-square, Dr. W. MILLIGAN, the President, being in the chair.

A discussion on the Value and Significance of Hearing Tests was introduced by Dr. THOMAS BARR (Glasgow) and Mr. SYDNEY R. SCOTT (London).

Dr. THOMAS BARR took up the nature of bone conduction of sound, the basis of the information derived from it in pathological conditions of the ear, and the difficulties, apparent contradictions, and possible fallacies of the various tests by bone conduction. Secondly, the present position of the various tests as to their value and significance.

Mr. SYDNEY SCOTT considered the mechanism of the sound stimulus in the cochlea in relation to tone range and tone acuity by air or other forms of conduction, and gave some results of concurrent clinical and pathological investigations.

The opening addresses were illustrated with lantern slides and some instruments which are not in general use.

It was decided to defer the discussion until May 17th.

CHELSEA CLINICAL SOCIETY.

Disorders of the Circulatory System.

THE annual clinical debate of this society was commenced on March 12th at St. George's Hospital, Dr. JAMES A. MANSELL MOULLIN, the President, being in the chair.

The debate was inaugurated by Professor Sir T. CLIFFORD ALLBUTT with a paper entitled "The Physician and the Pathologist on Heart Failure." He began by pointing out the inexactitude of our present state of knowledge of heart failure and of the conditions which produce it. Clinical physicians will give a ready answer to the question of what cardiac failure is, but they can often neither foretell it nor prevent it. The pathologists are no less ready to explain fatty degeneration, various kinds of myocarditis, degenerations of the *a.-v.* bundle, and other lesions. But the correlation of the two aspects, clinical and pathological, is still often lacking. The physician and the pathologist are plotting, each upon his own side of the hedge, and for lack of mutual coöperation the paths of both remain full of complications. There is, for instance, no definite criterion whereby to distinguish inflammation of the myocardium, in a fever case say, from dilatation due to mere lack of muscular tone. From these introductory remarks the audience would infer that Professor Allbutt intended to say little about valvular diseases of the heart, for there the lesions are partly mechanical and can be estimated, nor does death, as a rule, occur suddenly. Dilatation and hypertrophy were also passed over with a brief reference to the fact that there is no constant relation between them; dilatation, it was emphasised, is no gauge of the histological condition of the myocardium. If delineation of the heart's dimensions gives little trustworthy information as to the condition of the myocardium, what of the indications afforded by auscultation? Even they are uncertain; a slapping first sound may mean much or little; defective impulse beat and feebleness of the second sounds are only too often equally misleading. These physical signs are equivocal; they are not criteria. Again, vertiginous phenomena often accompany cardiac disease; but they are so often due to other causes that, taken alone, they, too, are often equivocal symptoms. The pulse, too, as experience has shown, is often deceptive; even the rhythm of the pulse has ceased to be accepted as a guide to myocardial damage. There are, however, two pulse signs that are significant. One is persistent alteration of rate and the other is pulsus alternans. As to the latter, we must remember Dr. James Mackenzie's warning that it may appear in a tracing when it cannot be detected by the fingers. A permanent change of rate, whether bradycardia or tachycardia, is of much importance. Let a pulse-rate be normally 65 to 70 when the patient is at rest; let it be found later to have become permanently 75 to 85 under similar conditions. Then the inference is that there is some profound change in the wall of the heart; yet even this is not an absolute criterion. Of dyspnœa, slight œdema and cyanosis, pulmonary crepitations, and many other similar signs, there is no need to speak, for they usually signify late stages of the malady and speak only too plainly for themselves. On fatty degeneration pathological opinion has undergone of late wide fluctuations, but the distinction between this and fatty infiltration still holds its ground, although the two merge one into the other. In the midst of fatty deposits the cardiac fibres may be well striated, and Aschoff even holds that fatty infiltration may be a sign of healthy activity. At any rate, it is possible for no clinical symptoms to be caused by advanced states of fatty change. In so-called chronic myocarditis we may find no greater correlation between the clinical symptoms and the pathological appearances. Fibrosis of the myocardium, again, is not infrequently found in hearts which have been quite efficient during life, and Dr. Hale White has lately described this condition as practically undetectable. Syphilitic fibrosis is, of course, another matter. The site of the lesions does not give very much help, and there may be complete destruction of both limbs of the *a.-v.* bundle without any clinical signs of dissociation. There are probably many subtle agencies of which we have no idea capable of determining the delicate poises of life and death. There is a world of surface tensions, viscosities, and other physical phenomena of which we know little; and there is a world of chemical reactions and ionic effects of which we know almost nothing. When we speak further of toxic influences we realise how near the precipice the heart may be. The riddle I have done so little to solve is that of sudden death in the man who has had no symptoms of illness and does not suspect that he is ill.

Sir LAUDER BRUNTON remarked that a good deal could be said for the cause of sudden death once assigned—namely, shortness of breath—as contrasted with cardiac failure. According to Casper, 50 per cent. of drowned people did not die from suffocation but from shock, both cavities of the heart being found completely empty. On the other hand, he had seen a case of aortic regurgitation within two minutes after death, and the appearance was typically that of strangulation, the face being deeply congested and the jugulars distended. In a case of sudden death from angina pectoris he had kept the heart going for nearly an hour by artificial respiration, although he had been unable to recover the

patient. In cases of sudden death from shock or from poisoning by hydrocyanic acid, digitalis, or diphtheria antitoxin no anatomical lesion whatever could be found in the heart, although no doubt chemical changes occurred in its tissues. He agreed that no single symptom was pathognomonic of fatty heart, but he thought that by taking several symptoms together a fairly correct diagnosis might be come to. He thought that a low blood pressure without any apparent cause in elderly people was to be regarded with suspicion. Death occurred in children from want of food, improper food, or imperfect assimilation. In adults these were the causes of death, but in addition there was over-work. This simile might help them in regard to the heart, which was in the unique position of having to supply itself with nutriment, with oxygen, and to remove its waste products. When the heart began to fail its own nutrition and its own oxidation were diminished and the functions of the kidney were also lessened. It had been shown that the heart was exceedingly sensitive to a lessened supply of oxygen, and if the respiration ceased long enough the heart was certain to stop. The respiration might cease because the heart had failed to send sufficient blood to the respiratory centres, and thus there was an intimate interaction between the heart and brain, as well as between the heart and kidneys. The accumulation of waste products might lessen the vitality of both heart and medulla, and diminish their power to utilise the oxygen which was supplied to them. Oxygen was a powerful stimulant to the heart. In a case of cardiac asthma he had seen the blood pressure in the brachial artery rise in ten minutes during the inhalation of oxygen from 75 millimetres to 150. The use of oxygen in a case of heart disease was sometimes very beneficial as a cardiac tonic. One required to be very careful in heart disease to avoid extra exertion. He thought by attention to the old-fashioned methods of securing elimination of waste products, and by the judicious use of appropriate diet and of cardiac remedies, the use of which was now so much better understood, a great deal might be done to prevent cardiac failure and sudden death.

Dr. SAMUEL WEST said that Sir Clifford Allbutt's destructive criticism showed them how little they knew. He himself was disposed to bring these cases of sudden cardiac failure into line with the toxic conditions spoken of by Sir Lauder Brunton. Intense poisons might be produced in conditions of which they knew but little, as in snake venom, or in uræmia and diabetes; and he could see no other supposition which accounted for some of these sudden deaths from cardiac failure. He was not prepared with any constructive theory; but it seemed to him that toxic influences formed the direction for future inquiry.

Dr. C. C. GIBBES related four unusual cases that had a bearing on the question of heart failure from myocardial degeneration. In the patients with scurvy there was pure fatty degeneration of the heart, the result of toxæmia, somewhat resembling that of phosphorus poisoning. In the case of old-standing aortic disease there was an acute toxæmia (from which the patient had apparently recovered), producing a myocardial intoxication sufficient to cause a sudden and unexpected arrest of the heart's action. The fourth case was that of a lady suffering from so-called fatty degeneration of the heart, although he believed the more correct classification would be fibro-fatty degeneration. The first indication of any heart disease was a sudden apoplectiform attack with complete unconsciousness for 36 hours; she had no paralysis, but was aphasic for two days after consciousness returned. She was then aged 67. During the following 18 months she had three other slighter attacks, but was then able to resume her ordinary mode of life for four years, when she began to have a series of syncopal attacks. During the following five years she had a great many attacks, and on several occasions it seemed as though she would never rally. However, these ultimately ceased and nothing fresh supervened until four years later, when she began to have epileptiform attacks after any fatigue. The worst came on during a train journey to Plymouth two years before she died. No symptoms presented themselves until after Exeter was passed, when she suddenly had an attack presenting all the symptoms of *petit mal*. She had eight attacks in all before the end of the journey. These attacks were obviously due to cerebral anæmia from heart failure, for they passed off at once when her head was in a dependent position. After this journey she was prevented from over-exerting herself and she had no more attacks. She died at the age of 84 from senile decay, without any signs of heart failure whatever. This case seemed to answer the question, Can the heart muscle of old age make any recovery from fatty degeneration? He said that, broadly speaking, fatty degeneration of the heart arose from some defect in the quantity or quality of its blood-supply. When cardiac failure resulted from the former they could do nothing, but when it was due to a defect in the quality of the blood recovery was possible, provided they could remove the cause. It could not be denied that the severest cases of scurvy (where both the voluntary and involuntary muscles were in a state of fatty degeneration) recovered, and the patient resumed active service. The same might be said of enteric fever. In the last case there was a peculiar sequence of attacks resulting from cerebral anæmia, secondary to heart failure, yet the patient died at the age of 84 from senile decay without showing any symptoms of heart failure. He suggested that more knowledge was required of acute myocardial intoxications and their effects, because in his belief such intoxications might and did occur unrecognised, the patient recovering without any permanent injury to the heart.

Dr. WILLIAM EWART referred to the variety and the importance of the "unknowable" or at any rate unknown quantities in the problem. The pathological degenerations and the toxæmia offered unlimited scope for speculation. The versatility of their theories was illustrated by the recent prevalence of the diagnosis of "myocarditis" which had now been supplanted by that of "heart-block." He drew attention to mechanical risks which were both demonstrable and manifestly disturbing to cardiac rhythm, and in particular to the gastro-intestinal distensions which also interfered with the paired mechanisms of respiration, and carried with them toxæmic and nervous reflex possibilities of evil. Gastric distension was often undetected through their forgetting that the crura of the diaphragm fixed the fundus to the spine, thus tending to guide its inflations into the left thoracic groove, behind the heart, at the expense of the more squeezable lung; and through their never looking for it in the back where it was to be found. This practical point he had often insisted upon, but it was first published in 1899 in a preliminary note, and in the Transactions of the Clinical Society of London, Vol. XXXIII, p. 202, "On Gastric Distension Upwards and Backwards." Clinical experience of its frequency and of its relief as a cause of urgent respiratory and cardiac symptoms had impressed upon him that, although it was only one of many, it was not the least frequent or the least potent of factors in the etiology of unexplained cardiac failure.

Dr. HECTOR MACKENZIE referred to various types of heart failure which were met with in practice. There were, first, the cases where the existence of heart disease had previously been unsuspected. The heart that failed had sometimes been passed as sound in a searching examination for life insurance only a short time before. Death occurred during sleep or perhaps with dramatic suddenness during the day. In these cases structural changes of the heart were usually present, such as fatty degeneration, fibroid disease, sclerosis of the coronary arteries. The clinical recognition of these structural changes in the absence of symptoms and physical signs was impossible. The immediate cause of death in these cases was obscure. Some seemed to be associated with dilatation of the stomach, and the fatal termination had followed a heavy meal and indigestible food. Of the younger cases some were probably examples of the condition known as status lymphaticus. Secondly, there were the cases of heart failure in which there had been for a shorter or longer period symptoms of functional disturbance, irregularity, rapidity, intermittence, anginal attacks, or dyspnœa, but there were no obvious signs of valvular lesion. In this group were included the heart after fevers, the influenzal heart, the heart after diphtheria, the heart in Graves's disease, the smoker's heart, and so on. Changes in the myocardium were generally found post mortem and were the effects of poisons acting on the heart muscle. Here symptoms and physical signs should lead to the recognition of myocardial disease and the adoption of the proper treatment which might tide the heart over the period of danger. Thirdly, there were the cases where there was old-standing valvular disease or adherent pericardium. There was a striking difference in the way in which failure came about in the mitral and in the aortic cases. In the case of the mitral lesions, the heart usually failed slowly, while in

the case of aortic incompetence sudden failure was not uncommon. Various explanations had been given of this difference, but one important contributing factor was the more usual presence in aortic cases of degenerative changes in the aortic and the coronary arteries, as well as in the myocardium. Rheumatic affections of the aortic valve were, on the whole, less dangerous than those which came on in middle life in association with atheroma of the aorta. If the heart muscle recovered its tone valvular lesions might be adequately compensated for and life might be prolonged to old age. The problem of heart failure was, as Sir Clifford Allbutt had pointed out, very complex, and it was quite as difficult to explain why in some cases heart failure was averted as why in other cases it came about. It was wonderful how good the recovery of a heart badly damaged in childhood might be, and how, by means of compensation, it might maintain its vigour throughout a long and active life. Even when compensation seemed to have hopelessly broken down and there was general dropsy with waterlogging of the tissues, orthopnœa, and rapidity and irregularity of the heart so that the end in failure seemed inevitable, the heart sometimes proved itself capable of recovering, the signs of impending failure disappeared, and compensation was again restored.

The debate was then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Discussion on the Treatment of Simple Fractures.

A MEETING of this society was held on Feb. 28th, Mr. J. M. COTTERILL, the President, being in the chair.

Mr. CHARLES W. CATHCART opened a discussion on the Treatment of Simple Fractures. He said that in later years a stimulus to the search for improved methods of treatment had been supplied by the Workmen's Compensation Act. The economics of the question, also, must attract attention, for every man unfitted for his work by a broken bone was a loss to the State. Within recent years the revival of massage, and its remarkable success in the treatment of sprains and bruises, the revelations of the X rays, and the antiseptic method itself, which allowed of the direct inspection of the broken bone, had called attention to the healing of fractures. For the treatment of a recent case of simple fracture there were three methods available: the old immobilisation method, the massage and early movement method of Lucas-Championnière, and the immediate operation method of Arbuthnot Lane. 1. The immobilisation method consisted in setting the fracture and fixing firmly not only the seat of fracture but also the joints above and below it until the bone was united, a period varying from six to eight weeks. The guiding theory that union could not take place if there was the slightest movement at the seat of fracture was now known to be erroneous, for broken ribs healed readily in spite of respiration, and the success of the massage and early movement had removed any lingering doubts. Rigid fixation impeded circulation and delayed the union of the bones, while it permitted the formation of adhesions. 2. The massage and early movement method of Lucas-Championnière. Here splints were used only to a limited extent to prevent displacement. Massage was used as soon as possible after the fracture and continued daily at first and afterwards at longer intervals. Movements of the adjacent joints, both active and passive, were cautiously employed. The theoretical bases were that rapid healing of the broken bone was promoted by the free circulation thus induced, while adhesions were prevented and the nutrition of the muscles maintained. Exact apposition of the ends of the bone was considered of less importance for future usefulness of the limb than free use of the joints and muscles. The objections were the greater time and attention required, and that it did not give good results in certain cases. 3. The immediate operation method, recommended especially in fractures of the long bones of the lower limb. The ends of the bone were exposed, the blood clot removed, and the broken fragments adjusted and held in exact position by steel plates fixed into the bone with screw nails. The theory was that restoration of function, especially in the lower limbs, demanded mechanical restitution of the shape of the bone, without which union was delayed, and pain when the limb was used by the altered strains in the bone. No account was taken of the additional laceration of the soft parts involved by the operation or of the delay in obtaining functional restoration owing to disuse of the muscles and joints during the healing of the wound. But the operation required much surgical skill and thoroughly reliable technique. He submitted that (1) it was not necessary to secure the joints above and below the seat of fracture more than was necessary for the patient's comfort and the limb might be massaged and the joints moved as required. This modified method gave good functional results in most fractures of the shafts in children as well as in adults (femur excepted) where there was no great displacement of the fragments nor severe laceration of the soft parts. 2 Massage and early movement gave more rapid results than the preceding method, although the final results might not be much better. This was the method of choice for fractures near or involving joints, and in fractures of shafts with much laceration of soft parts and irregularity at the seat of fracture, as long as there was not much angular or axial deformity or necessity for complete restoration of length of limb. 3. Immediate operation where reliable technique was available was the method of choice in transverse fracture of the patella in healthy adults, in joint fractures where the fragments mechanically hindered movement, where important muscular attachments were torn off and could not be approximated; where a nerve was involved; where soft parts prevented the fragments from coming into contact, or where angular or axial deformity could not be restored by manipulation or posture, especially in the lower limb; or again where the patient's occupation necessitated walking without a limp as in the army or police force. As to individual fractures: 1. In Colles's fracture reduction was advisable not only to prevent deformity but to re-establish range of movement of the wrist. The fragments should be brought into apposition under a general anæsthetic, and a splint provided for the anterior aspect. Warm fomentations and gentle massage gave relief. Massage was repeated daily. In correct massage muscles were soothed, swelling was rapidly reduced, and no pain caused. Passive movements were confined at first to the fingers and carried to the wrist as pain subsided. Active movements of the fingers began about the third day; the splint was discarded in from 10 to 14 days and the hand removed from the sling in about three weeks. Adhesions were seldom apparent when the massage and movement treatment was properly carried out. In this fracture operation was seldom called for, but immobilisation was likely to do much harm. 2. In Pott's fracture, while massage and movement was the method to be employed, operation might occasionally be called for. Prolonged fixation was likely to lead to stiffness of the ankle. 3. In fracture of the shaft of the femur in children Mr. Cathcart did not remember any case which did not mend with perfect recovery of function. He preferred treatment by extension and local splints after reduction under chloroform, combined with massage and early movement. He was satisfied that operation and plating for a simple fracture of the shaft of the femur in a child were quite unnecessary. In adults, however, surrounding muscles were massive and powerful, and swelled rapidly, so that no one could determine the form of the fracture or accurately adjust the ends even under the deepest anæsthesia. Consequently, he believed that the accuracy of alignment in different cases depended not on the surgeon's skill but on the nature of the fracture. In transverse fracture the broken ends would over-ride, separated by the thickness of the shaft. In oblique fracture the ends, though over-riding, would be more nearly in line. For his own part, in fracture of the shaft of the femur in adults he was not prepared to give up the massage and movement treatment in favour of operation, though he was willing to admit that the operative results might be better.

Professor ALEXIS THOMSON said he was a follower of Lucas-Championnière. If there was pronounced shortening beyond what might be overcome by extension with weights, he advised the use of Steinmann's apparatus—a pin inserted into the lower end of the femur, whereby extension equal to 40–50 lb. was obtained. To correct eversion, the long splint was very useful, as were also sandbags. Among his recent cases he found one case of fracture of the thigh up and walking about in six weeks; an old woman over 80 who could walk well in six weeks; and a man with fracture of the neck of

the femur, who was up on the twenty-first day and out on the twenty-eighth.

Mr. DAVID WALLACE thought it one's duty in every case of fracture to use the X rays not only to determine the displacement, but after the fracture had been set to determine if it had been properly done. Mr. Wallace used practically no splints in his wards. In Pott's fracture he kept the leg at rest, but did not use sandbags; in Colles's fracture he put the arm in a sling and encouraged the patient to make movements. In fracture of the femur good alignment was most necessary. If it could not be got without operation he would operate. He thought it more difficult to get a good result without shortening in the clavicle than in any other bone.

Mr. A. A. SCOT SKIRVING said that he operated more frequently now than formerly, but never on any fracture where there was no displacement. In Pott's fracture he thought there was a great tendency to displacement; it had to be carefully watched, the great risk being the development of traumatic flat-foot.

Mr. HENRY WADE narrated the procedure in the out-patient department of the Royal Infirmary, where massage and movement had been carried out for several years past. Quite exceptionally splints were used. Massage and passive movements were carried out from the first, and, even in the most severe cases, active treatment within the first week. In a number of cases the patient's wife was the masseuse, and they had been able to instruct her in a very short time.

Mr. E. W. SCOTT CARMICHAEL said that splints in the treatment of fractures should be looked upon as a rare accessory. Massage and movement required more supervision and care on the part of the surgeon and medical man than they usually got. Striking differences in results were seen according to the intelligence and skill of the masseur.

Mr. J. W. DOWDEN said that in treating a case in private he employed adhesive plaster, placed the arm in a sling, encouraged the patient to make active, not passive, movements, and he himself massaged the part. He had done away with splints and bandages, but unfortunately there was still shortening which had to be corrected by extension. In cases of fracture of the elbow if one began with a little passive movement, in the course of the next day the patient would be practically well.

Dr. H. G LANGWILL, in reference to compensation, said that the point of importance to his mind was not merely the union and fair restoration of movement, but the patient's ability to earn his livelihood. A great many of the old fractures would be found going about unable for work three or four months after leaving hospital but drawing compensation.

Dr. A. PIRIE WATSON said that in fractures of the upper extremity he did not consider the splint important, but he emphasised the point that massage and movement could not be begun too early. Massage should precede reduction; it was useful for overcoming spasm in the muscles. If it took more time at first, it saved time and vexation later. The best masseur was the doctor himself; massage should never pain but always soothe.

Dr. JAMES RITCHIE said that his practice was after reduction to apply a light splint with an elastic bandage, because of the tremendous comfort it gave to the patient.

Mr. J. W. STRUTHERS said that after the patient reached a certain stage, what he needed was voluntary movement, and this could best be obtained by work. If it were possible to get light jobs for such patients they would become fit in a much shorter time.

The PRESIDENT cautioned against putting patients into the hands of enthusiastic and muscular masseurs, which harmed certain cases. The long splint was an abomination.

Mr. GEORGE L. CHIENE and Dr. JOHN ORR also spoke, and Mr. CATHCART, in replying, said that the difficulty in compensation cases was that a large number of such patients were quite satisfied if they were getting compensation and they did not wish to return to work.

NEW LONDON DERMATOLOGICAL SOCIETY.—At a meeting of this society, held on March 14th, Dr. P. S. Abraham, the President, being in the chair, Dr. Tom Robinson showed a woman, aged 51, the subject of Myxœdema, who also presented several brownish, verrucose nævi upon the neck and abdomen, which had only appeared during the last 18 months.—The President showed a case of Unilateral Facial Hyperidrosis in a young woman aged 24.—Dr. C. G. Mack showed a little girl with severe Melanodermia in whom constitutional symptoms indistinguishable from those of Addison's disease had been present.—Dr. David Walsh showed: 1. A girl with Scrofulodermia of the Neck. 2. A young man with a curious lesion upon the front of the thorax, somewhat infiltrated and depressed. Two years ago there had been a deeply excavated ulcer upon this area, and the question of malignancy was raised. 3. A young man with old Keratosis Pilaris that was now complicated by the presence of a circinate, erythematous eruption upon the trunk and limbs, resembling a syphilide.—Mr. D. Vinrace showed a little girl with Multiple Lupus.—Mr. H. C. Samuel exhibited a case of Cheiropompholyx in a young woman who had been subject to periodic attacks.—Dr. G. Norman Meachen showed a boy with Favus of the Scalp, whose father was born in Amsterdam, but the mother and the boy were Londoners. The father, a sister, and a brother were also affected.

HARVEIAN SOCIETY.—A meeting of this society was held on March 14th, Dr. H. J. Macevoy, the President, being in the chair.—Dr. R. H. Cole read a paper on Hypochondriasis, its Significance and Treatment. He defined the condition as a subjective state of ill-health which was more or less chronic, and was out of all proportion to any disorder of the bodily mechanism. The hypochondriac was one who was painfully conscious of his organic sensations and which dominated his personality to the detriment of impressions from without. He stated that the conducting medium of the sympathetic system had not been found to be defective, and questioned whether the condition was the result of toxins or was due to an anomalous constitution of cortical neurons—possibly those connected with the visceral representation in the Rolandic area of the brain. Referring to the milder cases, for which little could be done except that they should be induced to follow their usual avocations, he based his communication on a scrutiny of 50 of the graver cases that had been under his close observation. Most of these cases required certification, owing to disorder of conduct dependent on illusions and delusions. These cases all belonged to one of the two classes of hypochondriacal melancholia or hypochondriacal paranoia, and were not associated with any obvious bodily disorder. They were further clinically considered in four groups according as the symptoms were general, or were associated with the alimentary tract, the sexual organs, or the brain. The suicidal element was discussed as especially marked in the sexual cases. Whilst the paranoiacs were regarded as inevitably chronic, the proportion of recoveries from hypochondriacal melancholia was relatively smaller than in other forms of melancholia. Some might be considered as having attacks of melancholia superimposed on a paranoiac basis. Differentiation was made between these cases and hypochondriacs that were general paralytics, cases of dementia præcox, epileptics, alcoholics, and cases of senile involution. As to treatment, although the milder paranoiacs derived benefit from change of surroundings the melancholics required rest and quietude. Freud's method of psycho-analysis was referred to in tracing the origin of delusions. Forcible feeding was resorted to in all cases of refusal of food, and a *résumé* was given of the medicinal and other modes of treatment adopted.—The paper was discussed by Dr. E. D. Macnamara, Dr. Maurice F. Squire, and Mr. Campbell Williams.—Dr. Cole replied.—Mr. V. Z. Cope read a paper on Latent Surgical Disease, by which title he indicated those pathological processes amenable to surgical treatment which might advance to a serious stage while yet giving no appreciable symptoms of their presence. He remarked that disease was manifested by derangement of function, alteration in physical characteristics, or simply pain. Function varied normally within such great limits that early changes due to disease were easily missed. Alterations in size and shape of internal organs were not detected early unless important structures were impressed upon; pain was an inconstant symptom, inasmuch as viscera supplied by the sympathetic system were not sensitive to ordinary stimuli. Latency was a feature of acute disease both at its inception and again after the acute stage; the early symptoms of an acute appendicitis might correspond to an advanced pathological progress, and the condition sometimes appeared quiescent even when an abscess had formed. Chronic infections of mucous

membranes which were furnished with diverticula and crypts frequently gave no symptoms except by occasional exacerbations which were mistaken for reinfection; nasal sinusitis and chronic gonorrhœa were cited as examples. The chronic granulomata and neoplasms were the common classes of disease which remained latent. Tuberculosis was especially prone to give no symptoms when it attacked the peritoneum or kidney. Syphilis was frequently latent for long periods; he mentioned a case of actinomycosis of the appendix which gave rise to no abdominal symptoms. Attention was called to the extraordinary latency of carcinoma of the colon and rectum and the need of early rectal and sigmoidoscopic examination emphasised. The late stage of carcinoma of the cervix at which symptoms sometimes first appear was also laid stress upon. Duodenal ulcer sometimes gave rise to no pain of any description; the first sign might be a severe hæmorrhage or general peritonitis. All the remarks made in the paper pointed to the important conclusion that early symptoms often meant late disease. The practical consequences of such conclusion were obvious.—The paper was discussed by Dr. W. Carmalt-Jones, Mr. Campbell Williams, and Dr. G. de B. Turtle.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on March 14th, Dr. W. B. Paterson being in the chair.—The following specimens were shown and described:—Mr. C. A. Adair Dighton: 1. A Large Osteochondroma removed from the auricle under cocaine anæsthesia. It was of interest on account of its huge size and also because it was diagnosed, previous to removal, as epithelioma. 2. A specimen illustrating Intrinsic Epithelioma of the Larynx. This showed involvement of the ventricular bands, ventricles, true vocal cords, and arytenoid cartilages. It was removed by complete laryngectomy.—Mr. G. C. E. Simpson: Tuberculous Osteitis of the Ulna.—Mr. Simpson and Dr. D. Moore Alexander: (1) Papilloma of the Nose; and (2) Carcinoma of the Kidney.—Mr. R. W. Murray: (1) Sarcoma of the Scalp; and (2) Enterolith from the Mesocolon.—Mr. W. Thelwall Thomas and Mr. H. C. W. Nuttall: (1) Recurrent Sarcoma in the Stump; and (2) Lymphatic Nævus of the Skin.—Dr. T. R. Bradshaw and Dr. E. E. Glynn: Chronic Tuberculous Pericarditis.—Mr. R. A. Bickersteth: (1) Enormous Urethral Calculus; and (2) three specimens of an Unusual Breast Tumour.—Mr. Bickersteth read a note on three specimens of Unusual Breast Tumour. He considered them to be fibro-adenomatous in character. The cystic nature of some specimens was due to hæmorrhages which might cause a rapid increase in the size of the tumour. Mr. Bickersteth laid stress on the importance of macroscopic pathology as well as microscopic and referred to old writers who had described these tumours accurately.—Mr. F. T. Paul said the adenomatous tumours of the breast commenced in two ways; one as a peri-acinous growth and the other an intracystic vegetation. The former developed into the fibro- or myxo-adenomata, and the latter into the cyst-adenomata. Though the two when fully grown might show points of resemblance, they could always be distinguished from each other, and were really essentially different, more so even than acinous and duct cancer.—Dr. Glynn agreed with Mr. Paul in regard to the pathology of these tumours.—Dr. Glynn read a note on the Detection of Anthrax in Industrial Material. He pointed out that the disease appeared to be spreading among domestic animals, and consequently a larger number of agriculturists were becoming infected. It was difficult to demonstrate anthrax spores in industrial material; two methods were commonly used—viz., agar-plate cultures and inoculation of guinea-pigs. The latter method seemed the better, and by its means anthrax spores had been found in 21·3 per cent. of 41 samples of raw hides, wool, &c., examined.—Dr. W. Blair Bell read a note on the Estimation of the Calcium Metabolism, and gave a description of a new clinical method of estimating the amount excreted in the urine. The method consisted in centrifuging and measuring the amount of calcium oxalate, precipitated by oxalic acid, the phosphates being dissolved with acetic acid, in a calibrated tube. The estimation was made by comparing the amount precipitated from the urine with that obtained in a similar manner from an artificial standard urine containing a known quantity of calcium.—Sir James Barr said that the profession was very much indebted to Dr. Bell for the great amount of work which he had undertaken in order to determine a clinical method for accurately estimating the amount of lime in the urine. This apparatus, which he now showed, would fulfil all the necessities of clinical work in respect of estimating the lime salts in the urine. His own method for estimating the amount of lime in the urine was a very simple one. He took an ounce of urine, neutralised it with a little ammonia, then added concentrated solution of oxalic acid with 5 per cent. of strong acetic acid. This precipitated the lime as oxalate of calcium, and all the phosphates were dissolved by the acetic acid. With some experience the eye soon recognised what was normal and what was abnormal. He also showed that the excretion of lime by the kidneys was much greater than was usually supposed.—Dr. H. R. Hurter referred to the simplicity and ingenuity of Dr. Bell's method of estimation. He expressed surprise and satisfaction that the results obtained by it had been shown to coincide so closely with quantitative chemical estimations. He suggested the possible employment of a saturated solution of sodium sulphate as an alternative reagent for precipitating the lime salt.—The council of the Institution have appointed Mr. Paul, Dr. Glynn, Dr. R J. M. Buchanan, and Dr. Bell to form a Pathological Reference Committee.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 6th, Mr. W. M. Willis being in the chair.—Mr. Willis showed a man whose thigh had been amputated for Diabetic Gangrene of the Foot. Spinal anæsthesia was employed and the patient had no shock following the operation. Since the operation the amount of sugar passed had greatly diminished. Mr. Willis also showed a case of Compound Subastragaloid Dislocation of the Foot; excision of the astragalus was followed by very good functional result.—Mr. H. B. Tawse showed a girl with a Median Cystic Swelling in the Neck. This was attached to the base of the tongue. It was thought to be a thyroglossal cyst.—Mr. K. Black showed a child 4 years old who had been operated upon for Cleft Palate and Hare-lip. The hare-lip had been operated upon when the boy was 1 week old and the cleft palate when he was 5 months old; the flap operation was performed. The result was only moderately successful as far as voice sounds were concerned.—Mr. C. H. Allen showed a man of 73 years; the patient had Sarcoma of the Thigh. Spinal anæsthesia (stovaine) was used. The limb was disarticulated at the hip-joint by means of lateral flaps. The patient suffered from no shock after this very severe operation. A microscopic slide confirmed the diagnosis.—Mr. P. Tresidder showed a girl 16 years old with Hypertrophy of the Mammæ. No operation was advised.—Dr. F. H. Jacob showed a man with severe Leucoplakia of the Tongue; in view of the possibility of future malignant disease removal of the tongue was urged by several of the members.—Dr. W. T. Rowe showed a man of 50 years with a mass of Enlarged Glands in the left groin and much œdema of the left lower limb. The symptoms had existed for three months and first started with pain in the left knee, then swelling in the groin, and finally swelling in the left leg. There was no disease of the rectum, perineum, nor of the genital organs. A diagnosis of lympho-sarcoma of the femoral glands was made and the case was considered to be inoperable.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 1st, Dr. J. Galbraith Connal being in the chair.—Dr. Leonard Findlay showed a man, the subject of myotonia, who gave no history of heredity and presented no evidence of neurosis, but was in other respects a typical case of Thomsen's disease.—Professor Walter K Hunter read notes of a case of Elephantiasis occurring in this country. The patient was a woman aged 61, in whom swelling of the legs had begun about 30 years ago, subsequent to repeated attacks of erysipelas. For many years the swelling had been so considerable as almost to prevent walking, and ulceration had occurred in various parts of both legs. On admission to Glasgow Royal Infirmary in October, 1911, the patient suffered also from marked ascites with splenic enlargement, no apparent pulmonary or cardiac valvular disease, but slight albuminuria. Within the following four weeks the abdomen was tapped thrice, but on each occasion the fluid rapidly reaccumulated, and the patient died on Nov. 26th. Post-mortem examination showed fatty degeneration of the cardiac muscle, dense perihepatitis and perisplenitis, great enlargement of the spleen, slight congestion of the kidneys, the capsules of which were adherent, and enlargement of the

retro-peritoneal glands. Microscopic examination by Dr. J. H. McNicol revealed marked multilobular cirrhosis and fine monolobular cirrhosis of the liver, thickening of the spleen capsule and trabeculæ, catarrhal nephritis, and hyperplasia of the lymph nodes of the retro-peritoneal glands. Sections of the skin of the lower limbs showed hyperplasia of the subcutaneous tissue, but no thickening of the epidermis nor unduly fibrous condition of the cutis vera.—Dr. J. A. Wilson read a paper on Keratitis as a cause of Myopia. He had collected a series of 100 cases of corneal opacities, and found myopia in 69 per cent., and that the average amount of myopia was a little over 3 D. The keratitis that produced the opacities was, with striking frequency, said to have followed measles. A few of the cases seemed to be due to ophthalmia neonatorum, and among those affected at an older age were some due to interstitial keratitis. In 21 cases there were opacities in one eye only, and of these 21 eyes 13 were myopic. In the 10 most pronounced cases in this section there was a total of 38 D. of myopia in the 10 nebulous eyes and only 1.5 D. of myopia in the 10 non-nebulous eyes of the same cases. Dr. Wilson then considered three possible ways in which alteration in the structure or mechanism of the eye might effect this result: (1) by stretching of the posterior segment of the globe as in ordinary myopia; (2) by increased curvature of the cornea; and (3) by yielding at the sclero-corneal junction. He found some evidence of change at the fundus; a fair proportion presented increased curvature of the cornea sufficient to account for the myopia, others presented slight increase, but not sufficient to account for the myopia, while others showed flattening of the cornea. There was also evidence in some cases of yielding at the sclero-corneal junction. The condition as a whole resolved itself into an inequality between the intra-ocular pressure and the resistance offered thereto. The treatment was discussed with this finding kept in view.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on March 6th, Dr. E. S. Reynolds, the President, being in the chair.—Dr. W. Fletcher Shaw read a paper on the Treatment of Placenta Prævia based upon 100 consecutive cases. He considered the best treatment for both mother and child was to leave nature alone provided the hæmorrhage was not very great and the doctor could remain in the house until the labour was over. If the hæmorrhage was more severe manual dilatation of the cervix followed by rapid extraction of the child with forceps or version gave the best results. Simple podalic version gave excellent results to the mothers but generally sacrificed the child. Packing, Champetier de Ribes's bag, and Cæsarean section he did not advocate for this condition.—Dr. C. Paget Lapage read a paper on Certain Forms of Fever of Obscure Origin in Infancy and Childhood. The more common causes of obscure fever were discussed, attention being drawn to otitis media. Blood diseases and Hodgkin's disease might be either acute or chronic with exacerbations. In such cases there might at first be no evidence of the cause until the blood was examined. Infection of the genito-urinary tract with the bacillus coli communis, either as an acute pyelitis or in a less severe form, was very important, and emphasis was laid on the need of careful examination of the urine in infants. A case of this nature with the complication of perinephritic abscess in an infant of 2 years was described. Fever due to gastro-intestinal disturbances, such as chronic intestinal indigestion, and recurrent fever due to excess of carbohydrates were also discussed, and a case of fever from overfeeding with breast milk described. Finally, meningitis was dealt with.

EXTENSION OF CHESTER INFIRMARY.—The scheme for the extension and renovation of Chester Infirmary is to be proceeded with directly the necessary formalities have been completed. The board of management has accepted, out of 13, the tender of J. Mayers and Son, of Chester, for £37,490. Although no appeal has yet been made, a sum of £32,338 has already been promised towards the £40,000 which it is estimated will be required. The President (the Duke of Westminster) has promised £3000; Mr. Albert Wood, of Conway, £12 500; Mr. George Barbour, £1000; Messrs. Frost and Sons, £1000; the Mayor of Chester, £20; and in addition there is an anonymous donation of £1000. £1337 have also been realised from the pageant.

Reviews and Notices of Books.

1. *The Individualization of Punishment.* By RAYMOND SALEILLES, Professor of Comparative Law in the University of Paris and in the College of Social Science. Translated from the Second French Edition (1908) by R. S. JASTROW. London: William Heinemann. 1911. Pp. xxxviii.–322. Price 16*s.* net.
2. *The Modern Prison Curriculum.* A General Review of our Penal System. By R. F. QUINTON, M.D., late Governor and Medical Officer of H.M. Prison, Holloway. London: Macmillan and Co., Limited. 1912. Pp. 276. Price 5*s.* net.

IN both of these books, but, as we shall see, from different points of view, the objects and methods of punishment for crime are discussed. The much larger work by Professor Saleilles consists mainly of historical and scholastic disquisitions on the principles of punishment, while Dr. Quinton's book reviews the English prison system in its relation to the assumed objects of punishment, reform and restraint.

1. M. Saleilles's conclusions regarding what he names the "individualisation of punishment" appear to us as neither new nor commensurate with the elaborate process of his argumentation. His style, moreover, is marked by a wearisome iteration of phrase, and often by an indefinite or inappropriate use of words. It must be remembered, however, that some of these blemishes may be attributable to the fact that the book before us is a translation. Considerably more than half of this work is devoted to a somewhat nebulous discussion of such time-worn questions as responsibility, free-will, determinism, &c.; and seeing that the author's object is to advocate the individualisation of punishment and the consequent necessity of studying the criminal's personality as a whole in its nature and surroundings, we need to know exactly what he means by the terms he frequently uses. Yet we nowhere find a clear statement of what he means by "responsibility," and we wonder what sense he attaches to the word "freedom" which he speaks of variously as "a state of positive action," as "a moral conception," as a "datum of the personal consciousness," as "a capacity," and as "based on an individual belief." It is true that this book is based on a course of lectures delivered from a legal chair, and does not explicitly profess to be a treatise on criminal psychology. But in so far as the author's plan involves the introduction of some psychological and biological assumptions, as evidenced, for instance, by the use of the word "natural" as applied to criminality, as well as of many psychological terms, the absence of precision of language and clarity of style is much to be regretted.

In advocating the adjustment of punishment, not to the social gravity of the actual crime committed, but to the complex personality of the individual himself considered as a whole and in relation to his surroundings, M. Saleilles does but reiterate what most modern penologists are essaying to compass—the appropriate treatment of the criminal rather than either the exclusively retributive punishment for the crime committed, or, on the other hand, punishment for the exclusively social purpose of deterring others. In expressing his views on this he propounds an arbitrary division of criminals into three classes: the accidental criminal, who is psychologically normal and therefore responsible; the "incorrigible" criminal; and the criminal who presents a "natural criminality" which is to be eradicated and is amenable to reformatory treatment. The purely *deterrent* punishment, he says, is fitted for the accidental criminal; he is "psychologically normal and needs no reform." For the "incorrigible" the proper treatment is either *detention*

or *elimination*, in order to protect society. *Reformatory treatment* is to be reserved for the large intermediate class who are assumed to be "natural criminals." Yet, when speaking of the accidental class, assumed to be normal and responsible, the author contends that their normality is "not an original and wholly spontaneous condition, but a slow and progressive one [? acquired] which may disappear." For all this he justifies for them, as we have seen, a purely deterrent punishment. The true criminal, however, of the large intermediate class which he deems reformable is, in his opinion, a "natural criminal," an abnormality. But why "normality" should be at least partly of slow and progressively acquired growth, while abnormality is "natural," or what is meant by all these terms is nowhere explained; and it would thus seem that no one can be blamed for not understanding the implied denial of "responsibility" (whatever this word may be taken to mean) to the *reformable* criminal merely on the dogmatic assumption that he is "abnormal."

Many modern writers about penology do not perceive the simple fact that whatever "treatment" be applied by law to the criminal or law-breaker of any kind—no matter what the explicit object of the treatment may be—*must* be "punishment," and by consequence disagreeable. If a man be physically or mentally hurt, or fined, or deprived of anything of which he feels the loss, or restrained in any degree whatever from the full exercise of the legal liberty which is common to all men, that man *is* punished; he suffers pain. Further than this, whatever may be preached to the contrary, the most enlightened public opinion justifies that suffering on the ground, perhaps not always explicitly recognised, of the still living principle of retributive justice. If this principle were no longer vital, society itself would disapprove of inflicting pain of any form on a man in order only to deter others from committing crime; or, indeed, on the sole pretext of reforming him or doing him good. Be this, however, as it may, there is no possible system of dealing with or treating a criminal without "punishing" or hurting him. We may remark, by the way, that though there is no object in detaining insane persons, except for the good of themselves and the community, the pain of loss of liberty is suffered by them as much as, or perhaps more than, by most criminals; and that in the deprivation of privileges within asylums many insane persons both feel and profit by this form of punishment, which is practised and justified on the principle of deterrence applicable both to the individual concerned and to his fellow inmates.

Professor Saleilles, with many of his contemporaries, fails to perceive these things. If he had followed the example of a great criminal judge in this country, and insisted on the necessity of a clear conception of the meaning of the word "responsibility" in relation to crime and its punishment, he might have saved himself from much of the laborious logomachy which mars this book; and need not have entered into the arena where Free Will and Determinism are eternally fighting for the crown. Both of these combatants, like materialist and idealist philosophers, are practically at one in their methods when dealing with human affairs, however they may disagree in theory. Though the idealist may preach that science can deal only with phenomena and their inter-relations, he cannot, in practice, rid himself of the dominant notions of causation and reality; nor can any social student or moralist, whatever his "credo," deny the practical freedom, within the everyday sphere of action, of most men to choose their course of conduct. Responsibility, in the only sense which concerns penologists, must mean, as Sir James Stephen contended, "liability to punishment"; and, as Dr. Mercier has shown in his clearly reasoned book on "Criminal Responsibility," the further qualification is needed that the liability must be "right"—i.e., in accord with the general contemporary social sentiment. But M. Saleilles, in attempting to rid himself of the difficulty of dealing with the notion of the responsibility of criminals, which he admits that criminologists cannot afford (*sic*) to ignore, is led to indulge in such writing as this (see p. 272): "Instead of measuring or estimating the degree or extent of freedom exercised by the criminal we should look at the relative depravity of the emotion that incited to action. The subjective criminality of the action is to be substituted for responsibility." Even if this remark should be deemed intelligible when studied in its context, it is not easy to see how it helps the student of penology.

A little further on (p. 274) we find it written: "Having thus reached the heart of the question, let us supply a definite constructive system of specialised punishments to be applied according to the moral temperament of the criminal." Here follows more preliminary postulation before the practical issue is reached. There is, it is argued, static (or passive) and dynamic (or active) criminality; active criminality should determine the duration of the punishment; passive criminality, or "character," should determine the nature or kind of punishment. Criminals, therefore, must be classified psychologically in order to reach an adequate classification of punishments. But here the author makes a halt, or almost a *volte-face*, and warns us against the "serious primary difficulty of losing ourselves in minute details and distinctions." We must not go too far into the investigation of *causes;* "we lack a sufficient scientific criterion for this; we must not aspire to the impossible lest we descend to the ridiculous. All we can do is to classify criminals with reference to the provisions at our command, which are limited to measures of repression, together with suitable varieties of discipline." "The *law* should not go far into the causes and types of crime, into heredity, environment," &c., but should "confine itself to social standards" and deal chiefly with the *degree* of crime. The classification should be adapted to the results which the law seeks to secure. Finally, after more circumlocution, the author urges that there is a fundamental and ancient three-fold classification which is "classic" in its traditions and has not yet been replaced. It includes (1) offenders without true criminality; (2) offenders whose criminality is but superficial; and (3) offenders tainted with a fundamental, and thus ineradicable, criminality—the incorrigible. This, he urges, is a "fundamental" division, to which should correspond the three classes of punishment—"deterrent," "corrective," and "protective," this last word implying, we presume, solely the protection of society. This conclusion is offered as a "basis and point of departure for future criminal law"! Apparently, if the inquiring penologist examines this somewhat addled egg, which has undergone such a tedious and prolonged term of incubation, the pabulum he will find is this: the offender who has "no true criminality," or, in other words, the "normal" man, must be punished for the sake only of deterring others. The offender whose criminality is superficial must be punished with a view to reform, while the "incorrigible" is to be punished for the sake of society; or, in other words, the least criminal and the most criminal are to be punished for the sake of others only, while the intermediate offenders, who are by far the more numerous, are to be punished primarily for the sake of themselves. To round off this gospel of penology, which is something strange though not altogether new, M. Saleilles says that even the *judicial* individualisation of punishment (which he has before stated to be the best kind of individualisation) is inadequate; that the classification of offenders and punishments must be general, as it is

impossible to consider an indefinite variety of punishments adjustable to the precise moral temperament of each individual. Therefore the law must give to the *administrators* of punishment sufficient power to adjust discipline to educational and moral requirements. For reformation and moral regeneration no fixed term of punishment is appropriate. The criminal must be treated like a patient—in the moral sphere. And the treatment he prescribes is the indeterminate sentence and detention in institutions of the type first known in the establishment of the Reformatory at Elmira in the State of New York.

It is clear to anyone duly conversant with the practical side of penology as well as with the principal literature of the subject that, however erroneous and nebulous, or however profound and scientific, M. Saleilles's theory and doctrine may be deemed by critics to be, the three classes of offenders that he exhibits to the reader of this book are just the same as have long been recognised under other names by most modern penologists: the accidental offender (a large class), whom *detection* alone is generally sufficient to "cure," whatever the nature of his "crime" may have been; the ordinary heterogeneous criminal of many colours (also a large class), who is but little deterred by loss of liberty and other apparent inconveniences which form the sum total of most modern "punishments"; and the "incorrigible," who, whether approximately sane or frankly insane, cannot be in any way impressed for the better by any punishment at all. But it must be remembered that there is no "natural" class, including all incorrigibles; nor can the diagnosis of incorrigibility be made without personal study of each case. It may indeed be said that after deducting such criminals who, apart from their actual crime, show marked evidence by their general conduct of mental defect in some sphere, it is rash to say that anyone is incorrigible. Even the ablest and most inveterate offender, who forges or steals or embezzles as a profession in spite of frequent detection and punishment, and without the initial temptation of poverty, may either from very weariness or belated reflection turn over a new leaf. But there is no means in such cases of making an early forecast of the probability of such a spontaneous reform in any individual case, and most of them should be detained for the benefit of society.

As the author proceeds to the more practical or constructive part of his essay he seems somewhat less troubled with the numerous speculative difficulties which he has raised and laboured to grapple with in the earlier pages. Treating in his last chapters on the legal, judicial, and administrative individualisation of punishment he warns against "false sentimentality" and says: "Obviously punishment must be severe, otherwise it would not be a penalty; it would cease to intimidate"; and he congratulates, in all justice, "the French school on its acceptance of truth, wherever it finds it, without too close allegiance to systems—a school of practical methods and happy solutions, one of good sense and fine Gallic insight." In spite of our criticism of this particular French book our French *confrères* will doubtless justify us in claiming some "Britannic" insight into penological questions on similar grounds to those put forward by M. Saleilles on behalf of his countrymen. While freely admitting that the criminological literature of England cannot compare with that of France either in quality or quantity, the course of penal legislation in Great Britain shows that we too adopt practical methods and happy solutions without too close allegiance to systems.

2. A study of "The Modern Prison Curriculum," by Dr. Quinton, will help to justify the claim just made. The author, who is an experienced medical officer and prison administrator, writes about what he has seen and reflected upon himself. He has, he says, "no startling theory to propound on a subject about which the evident differences of opinion are consistent with a genuine desire to promote progress." The general view he holds recognises the interests of society as a legitimate factor for consideration in the settlement of penal policy, but does not ignore the rights or interests of the criminal. We think that his book successfully supports his contention that the interests of society and those of the criminal in this country correspond in the long run much more closely than most people imagine. Although he is careful to emphasise his opinion that reluctance to punish and reluctance to detain criminals are signs of the times which are not wholly without drawbacks, Dr. Quinton fully recognises the value of the most modern methods and proposals in the direction of reforming criminals and of the prevention of crime, such as have been instituted by the English modification of the Elmira treatment, known as the Borstal system, or adumbrated in a late scheme for "suspension of sentence." In the whole of this general review of our penal system the author shows that he is well informed in the literature of penology and of the practice of other countries, and that his comments on both the virtues and defects of existing systems of punishment are the result of no small knowledge.

The chapter on "Reclamation" appears to us to give due weight to the increased importance rightly attached by modern public opinion to all possible efforts directed towards the reformation of persons convicted of crime, while keeping clearly in view the desirability, as well as the general *inevitability*, of the element of punishment, if only that of enforced detention, in order to compass this object. In this connexion the actual advantages and proved success of the Borstal system in England in the treatment of youthful offenders are well set forth. This system, devised by Sir Evelyn Ruggles Brise, has been tried now for several years, and was definitely formulated and established by the Prevention of Crime Act of 1908, which ordained that certain classes of juvenile criminals could be sentenced directly to reformatory treatment instead of being sent to prison. We find also in this chapter a thoughtful appreciation of the new legislation contained in Part II. of the above-mentioned Act, which is concerned with the treatment of persons sentenced to penal servitude and found by the court to be "habitual criminals." This legislation is but now about to take effect, all criminals sentenced to preventive detention since the passing of the Act having been obliged to serve their penal sentences before entering on the period of further detention. It is not possible, therefore, at present to make any useful forecast of the result of this measure, which is intended to prevent the commission of crime by the habitual offender and at the same time to encourage all possible efforts at reclaiming him. It appears to us that since the maximum period of preventive detention is but ten years, and since the Secretary of State has power to shorten this period at any time by earlier discharge on licence, the success of this part of the Act will depend wholly on the way it is administered in each case. This experiment in the direction of the "indeterminate sentence" will be watched with deep interest by all students and practical administrators of penal measures.

We congratulate Dr. Quinton, who had the advantage of exceptional opportunities of studying mentally defective criminals at the convict prison at Parkhurst for many years before he was appointed to the Governorship of Holloway prison, on having made such good practical use of his professional knowledge and experience. Although this book will primarily attract the attention of penologists, it will not fail to be of considerable interest to many medical readers.

The Internal Secretions and the Principles of Medicine. By CHARLES E. DE M. SAJOUS, M.D., LL.D., Professor of Therapeutics in the Temple University of Philadelphia. Fourth edition. London: Stanley Phillips. Philadelphia: F. A. Davis Co. 1911. Two Vols. Pp. 1873. Price 50*s.* net, cloth; half morocco, 63*s.* net.

IMPRESSED with the shortcomings of physiological science as at present set forth by its votaries, the author attempts in the book before us to construct a new system of physiology based on the importance of the ductless glands. We cannot attempt within the compass of a review to give more than an imperfect sketch of his *novum organum*. Put shortly, the basis of life is the secretion of the suprarenal glands, which supplies the oxidising principle to all living tissues. This secretion is carried to the lungs by the vena cava inferior, and there some of it is taken up by the erythrocytes and combined with hæmatin to form hæmoglobin. The important part of the blood is, however, the plasma, the red cells only forming a storehouse for the "adrenoxidase" as the principle is named. The plasma of the blood penetrates all organs and excites their activity. Thus, carried to the muscles it combines with myosinogen and gives rise to muscular energy. Carried to the nerves, it produces nervous energy, by the action of the oxidising ferment on the lecithin of the myelin sheaths, which stands to nerve in the same relation as myosinogen to muscle. The so-called axis-cylinders are merely tubules through which the ferment flows. Indeed, not only is adrenoxidase a ferment, it is the ferment of ferments, as it enters into the composition of all ferments, which consist of this substance in combination with nucleo-protein and a specific zymogen. In the case of the pancreatic ferments, the zymogen of trypsin is secreted by the islands of Langerhans, that of the amylopsin by the other cells of the gland. Products of digestion are taken up by the leucocytes and by them conveyed to the cells of the tissues. Thus neutrophile leucocytes supply myosinogen to the muscles, basophile cells convey myelin, derived from fats, for the use of the nervous system.

But if the suprarenal glands are thus all-important, they are themselves subject to the control of a higher centre—the pituitary body. This organ is in part a test organ, the homologue of the "osphradium" of mollusca, which is supposed to test the purity of the water in which the animals live; but it is also a most important nerve-centre, controlling all vital functions. Among other duties, it controls the immunising processes of the body, regulating as it does not only the suprarenal functions but also those of the thyroid and parathyroid bodies. Of the substances active in immunity the amboceptor is only adrenoxidase, while the opsonins and agglutinins, and to some extent antitoxins, consist of thyroid secretion. The latter is also an important stimulant to cellular activity, its iodine constituent regulating phosphorus metabolism. Incidentally Dr. Sajous denies that the cells of the thyroid are epithelial in nature, regarding them as leucocytes. The concluding chapters of the second volume set forth a theory of therapeutics founded on the foregoing physiological basis. Interspersed among the theoretical discussions are valuable accounts of the different diseases, such as Graves's disease, acromegaly, cretinism, and so forth, generally recognised as due to disturbances of the functions of the ductless glands.

So far as the new physiology is concerned, we must admit that, taken in bulk, it is rather too big a dose. That existing physiological knowledge is sadly defective we readily admit; indeed, if we were to subtract from an ordinary text-book all descriptions of instruments and all purely hypothetical explanations, the remaining body of facts—or as Sir Clifford Allbutt would prefer to say, truths—could be compressed into a very moderate-sized volume. But Dr. Sajous's system is too revolutionary to be accepted without much stronger evidence than he here affords. Indeed, the arguments, though supported by a vast amount of painstaking research in the byways of physiological literature, seem rather flimsy. Thus it hardly follows that because iodine and phosphorus react chemically, therefore the thyroid secretion, containing iodine, is the controlling agent in vital phosphorus metabolism. Nor do the facts that chlorine and hydrogen combine at a temperature of 39·5° C. and that the warmth of the gastric cavity is about 38° C. help very much in understanding the formation of gastric juice. These are merely samples of the reasoning employed. If, however, we cannot subscribe to the author's conclusions we cannot fail to recognise the diligence with which he has collected all possible information bearing on the subject of his studies, while some of his speculations, as, for example, the suggestion of the homology of the pituitary body, are interesting and ingenious. Incidentally, we may question whether oxyphile cells are to be understood as "oxygen-loving," the term merely implying affinity for "acid" dyes; while "*extra corpore*," a frequently recurring phrase, would, we fear, hardly pass muster in an English school.

An Index of Treatment by Various Writers. Edited by ROBERT HUTCHISON, M.D. Edin., F.R.C.P. Lond., Physician to the London Hospital and Assistant Physician to the Hospital for Sick Children, Great Ormond-street; and H. STANSFIELD COLLIER, F.R.C.S. Eng., Surgeon to St. Mary's Hospital and Surgeon to the Hospital for Sick Children, Great Ormond-street. Sixth edition, revised and enlarged. Bristol: John Wright and Sons, Limited. 1911. Pp. 1039. Price 21*s.*

THE first edition of this excellent work was published in November, 1907; the fact that it has now reached the sixth edition is sufficient proof of the extensive favour with which it has been received by the profession at large. In preparing a new edition, opportunity has been taken to revise thoroughly all the old articles and to include several new ones. Amongst those appearing for the first time are puerperal sepsis, hydro-, photo- and thermo-therapy, and treatment by carbonic acid snow. The last-named agent is of special interest to dermatologists. For instance, capillary nævi may be completely removed by a single application of forty seconds' duration with firm pressure. Moles and warts can also be successfully removed by this method. One of the latest of the many satisfactory applications of solid carbon dioxide is in the treatment of rodent ulcer. Details are given of the preparation and application of the remedy.

We can cordially recommend this work to all practitioners. It contains a vast amount of valuable information arranged for ready reference. It is most complete as regards both medical and surgical affections, and therefore will be found especially valuable to the general practitioner.

A Manual of Diseases of the Eye. By CHARLES H. MAY, M.D., New York, and CLAUD WORTH, F.R.C.S. Eng. Third edition. London: Baillière, Tindall, and Cox. 1911. Pp. 427. Price 10*s.* 6*d.* net.

IN the third edition of May and Worth's "Manual of Diseases of the Eye" the general character of the work is maintained, and it has been brought up to date. The most important addition is a chapter on vaccine therapy, by Mr. S. H. Browning, bacteriologist to the Royal London Ophthalmic Hospital, than whom no one in England is better qualified to write upon this special branch of the subject. The wealth of coloured and other illustrations, the conciseness and accuracy of the text, and the wholly practical nature of the teaching make this book especially attractive to the student of medicine who has only a limited time to devote to this particular branch of his subject. For him,

and as an introduction to more exhaustive study of ophthalmology, the book can be confidently recommended as a reliable guide. Considering the severe restrictions which the authors have set themselves, a wonderful amount of information is conveyed in a small space. It is well marshalled, so that the relative importance of various pathological conditions is duly emphasised—a point not infrequently lost sight of in some larger text-books. Particularly commendable are the short anatomical introductions to the chapters on the diseases of the different structures. They show an appreciation of the scientific basis of pathological detail which cannot be too thoroughly inculcated into the student's mind, and which creditably distinguishes this work from the ordinary cram book. The use of heavy type and short paragraphs simplifies the reader's task, and occasional tables of differential signs and symptoms facilitate recapitulation.

Modern German Hospital Construction. By WILLIAM MILBURN, jun. London: Royal Institute of British Architects. Pp. 142. Price 3*s.* 6*d.* net.

IN a compact form and with numerous illustrations Mr. William Milburn, jun., A.R.I.B.A., has given us a graphic description of the construction of hospitals in Germany. This is a welcome contribution to a highly technical subject, and it is good to see with what scientific care and studious forethought the Germans have endeavoured to build hospitals that will render the maximum service. Hospital building in Germany is not left, as it recently was with us, to the fancy of a few charitable persons; it is treated as a national problem. The compulsory insurance against sickness makes the prevalence of illness a matter that affects the entire population, since those who are well have to pay for those who are sick. Every town must provide at least one hospital, and the municipalities of large towns build, equip, and maintain several hospitals. All classes are admitted to these hospitals, but the patients pay from 2*s* 6*d.* to 15*s.* or 20*s.* per diem, according to the accommodation provided. The medical and surgical staff are paid for their services. The university hospitals, or "Royal Clinics," are the centre of medical education and study, and these are maintained by the State. Nevertheless, something yet remains of the old days when the poor had to depend on private charity and voluntary subscriptions, generally organised by some religious body. Thus, we still have denominational institutions in Germany of the kind so well typified by the Jewish Hospital at Cologne.

As a great number of the hospitals are of recent construction the sites selected have been suitable in view of the modern extension of the large towns. Care having to be taken to secure ample space, pure air, light, and freedom from noise and dust, the hospitals are mostly found outside the towns and on the side where the prevailing winds should not be overcharged with the results of commercial industry. The area of the site per bed varies from 72·7 square yards at St. Georg, Hamburg, to 152 square yards at the Virchow Hospital, Berlin. But for the most part it seems to us that the German hospitals are too large. The Hamburg Eppendorf and the Virchow at Berlin have more than 2000 beds, and in our opinion half that number of beds are as much as can be conveniently managed in any one establishment. Nearly all the large towns have one general hospital, but there are two at Dresden, three at Hamburg and Munich, and four at Berlin. A general hospital should provide for all class of medical and surgical cases, including maternity, children's diseases, and venereal diseases. The greater part of the medical staff have to reside on the premises. The nursing staff is organised on much the same lines as in England. The building of modern hospitals date from the construction of the Moabit Hospital at Berlin in 1872. It is acknowledged that the great reform then commenced is based on the lessons learnt during the Franco German war of 1870–71. The Moabit Hospital consists of pavilions of only one storey well separated one from the other.

Mr. Milburn gives the ground plan of all the leading hospitals, and notably the Eppendorf Hospital at Hamburg, with its 2150 beds and its staff numbering 820, of whom 670 live on the premises. There are here no less than 100 separate buildings, of which 85 are for the patients. Then the details are considered, such as the construction of the administrative blocks and their relation to the reception hall. The possibility of patients introducing infectious diseases and the painful sights when accident cases are brought in are also taken into account. At Charlottenburg West End this difficulty is overcome by admitting patients to a one-storey wing with a separate entrance on one side of the administration block, and this is balanced by a similar wing at the other end containing the dispensing department. Then we have plans and photographs of aseptic and septic operating theatres, for both are provided in most of the hospitals, that of St. Georg Hospital at Hamburg being considered among the best. The methods of heating and ventilating are dealt with, though only briefly, both with regard to operating theatres and the sick wards. In this respect we are told that in mild weather natural ventilation is preferred, and for this purpose the English sash window is not approved, for only half the area of the window can be opened. Mechanical ventilation is indispensable in the colder weather, and in some cases it is necessary to filter and humidify the air before it is admitted into the wards. The usual amount of air demanded in the specifications for large wards is 2650 cubic feet per bed renewed twice per hour. In the lavatories the change should be five times in the hour.

Much other useful information is given on thoroughly practical questions, and the volume should prove of use to all who are interested in hospitals.

Handbuch der Pathogenen Mikroorganismen. Herausgegeben von Dr. W. KOLLE und Dr. A. VON WASSERMANN. Zweite vermehrte Auflage. Jena: Gustav Fischer. 1911 and 1912. Pp. 200, 128, and 160. Price 5 marks each.

THE third instalment of the second edition of this important work deals with the general morphology and biology of pathogenic micro-organisms; and it completes the account of the occurrence of pathological organisms in water, in various articles of food, and in the houses and clothes of human beings. The next section is concerned with the general methods of bacteriology. The microscope with its various adjuncts suitable for bacteriology is described, and a good account is given of the methods of examination of preparations, both unstained and stained. The last portion of this part deals with the culture of bacteria. In the fourth instalment this subject is continued, and is followed by a section dealing with the examination of tissues, air, and water for bacteria. The employment of animals in the investigation of bacteria is described, and the final chapter deals with auxiliary apparatus in the investigation of bacteria. The fifth instalment consists of a very full account of the bacteriology of cholera and the question of the possibility of producing immunity against it. The thoroughness with which the subject is treated will be recognised when we say that the account of the cholera bacillus occupies 109 pages. The subject is considered from every possible point of view with satisfactory results.

The re-issue of this valuable work contains much more than the first edition, and will be most valuable to the bacteriological laboratory.

LIBRARY TABLE.

Shop Slavery and Emancipation. By WILLIAM PAINE. With an introduction by H. G. WELLS. London: P. S. King and Co. 1912. Pp. 125. Price 1*s.* net.—The hard lot of the shop assistant, more especially in the drapery and grocery trades, is only one more of the evils resulting from modern industrialism and the reign of the big store. Mr. Paine draws a dismal picture of the wretched state of the shop assistant under the living-in system, a picture which Mr. Wells, who speaks from personal experience, says is in no way overcoloured. Mr. Paine's remedies may be divided into two. Firstly, in order to get rid of the "living-in" system he strongly recommends the establishment of hostels, such as those inaugurated in Edinburgh by Professor Geddes for young graduates and students of the University (p. 60), or again for shop assistants, sempstresses, clerks, and the like, both men and women, in a Midland manufacturing town. If such a system is found to be successful in these two instances there should be no insuperable difficulty in extending it to other towns. The other, and more general, remedy is that sketched by Mr. Paine in Chapter VI., entitled "The Way Out," a plan of which Mr. Wells says, "I do not at present see any prospect of its immediate and special application to the employees of the distributing trades." Mr. Paine's idea is, if we understand him rightly, the formation of an organisation which should be capable of bringing about a sectional or universal strike. The first step towards this organisation is "the reckless love of comrades, and the development through it of a reckless note of desperation." We can quite see the point of view from which Mr. Paine writes. Every wage or fee or salary earner wishes for reward proportional to work, and also for the right to do his work without subjection to irritating control. These are the benefits for which the medical profession is at present fighting, and there is no reason why other professions, occupations, or trades should not fight for them too. Mr. Paine's little book is certainly worth reading and thinking over, not only by the employers chiefly concerned, but also by the rest of the British people, who are all "shoppers" at one time or another, and especially by members of friendly and coöperative societies.

Heredity in Relation to Evolution and Animal Breeding. By W. E. CASTLE. London and New York: Appleton. 1911. Pp. 184. Price 6*s.* net.—Dr. Castle, who is professor of zoology at Harvard, is the leading exponent in the United States of experimentation and theory along the line initiated 50 years since by Mendel. In the volume before us he sums up in a perfectly intelligible fashion the leading conclusions to which cross-breeding along Mendelian lines has led us, conclusions with which we are in this country very familiar by virtue of the striking work of Professor Bateson and others who think with him. The author addresses this little *résumé* to students and general readers, which latter class is always hopefully viewed by those of us who write books. It is to be doubted, however, whether the general reader comes up to our sanguine expectations. The present volume, for example, needs for its due understanding a very considerable appreciation of the minute histology of the sexual cells, to attain to which understanding needs much study at first hand. For the real student, on the other hand, who is not well acquainted with the department of biology interpreted by Professor Castle, this work contains an admirable survey of what he must know in the matter before proceeding to deepen and widen his outlook upon the problems of heredity, and to such it is to be heartily commended as a valuable introduction. The student can hardly stumble while following Professor Castle through the graduated series of conclusions to which the facts of crossing lead. The author begins his illustration of the Mendelian theory by a perfectly simple case of mating of a black and a white guinea-pig; these and their offspring are figured in reproduced photographs, and the whole process of crossing is displayed in a diagram so plain that it can be followed by the most slowly moving intellect. Thereafter an expansion and inevitable complication of the previously simple facts should find the reader prepared.

MISCELLANEOUS VOLUMES.

WE have received a number of small text-books, chiefly of a practical type, on chemistry, physics, chemistry and physics, analysis, elementary hygiene, and so forth, which may conveniently be reviewed together.

In *A Practical Hygiene* (Newcastle: Doig Brothers and Co., Limited. Pp. 31. Price 1*s.* 4*d.* net) Mr. J. STEPHENSON has collected an interesting series of simple experiments illustrating hygienic principles and applications. The work is quite well done and the directions are free from ambiguity. The illustrations are neat and the instructions for performing the more important tests are in the main in tabular form. Air, water, food, soil, poisons, heating, and lighting are amongst the subjects and materials which the reader is instructed to examine.——*Practical Chemistry for Medical Students*, by ALEXANDER CHARLES CUMMING, D.Sc., and J. WALKER (Edinburgh: James Thin. Pp. 171), is the title of a book prepared for the use of students attending the medical practical chemistry class in the University of Edinburgh. From a glance at the subject matter it is evident that the book will meet the requirements of students elsewhere. It is essentially a companion for the laboratory bench, and the paragraphs are eminently practical in character. As far as we have examined them the tests described are free from pitfalls. The sections on preparation of simple salts and volumetric analysis are valuable.——*Experiments in General Chemistry*, by JOSEPH H. JAMES, B.S., Ph.D., and JOHN A. SCHAEFFER, A.M., Ph.D. (New York: McGraw-Hill Book Company. Pp. 118. Price 4*s.* 6*d.*), is written chiefly for engineering students. The authors put the experimental directions in clear terms, and have chosen materials which are appropriate for an elementary practical course with engineering applications in the foreground. The sections on galvanising, water purification and clarification, common materials and rocks, industrial applications of the heat developed in intense chemical reactions, are cases in point. The book thus supplements "a course of lectures and quizzes," and so may be a useful companion to the general text-book.——The same publishers have issued *Experimental General Chemistry*, by JAMES H. RANSOM, Ph.D. (Pp. 145. Price 4*s.* 6*d.* net), which exclusively presents the experimental side of general principles. The object of the book may be gathered from a statement in the preface to the effect that the experiments set out require about 125 hours of laboratory work, but by omitting a few of those marked "optional" the work can be completed in three hours per week. This suggestion narrows the scientific value of the book.

In *A Handbook of Physics and Chemistry*, by HERBERT E. CORBIN, B.Sc.Lond., M.R.C.S. Eng., L.R.C.P. Lond., D.P.H., and ARCHIBALD STEWART, M.A. T.C.D., B.Sc. (London: J. and A. Churchill. Fourth edition. Pp. 519. Price 7*s.* 6*d.* net), we find evidence of an earnest endeavour to help the student preparing for the Conjoint Board examinations, and the syllabus of work in physics, inorganic chemistry, and organic chemistry issued by the Royal Colleges of Physicians of London and Surgeons of England has largely guided the authors as to scope. In the present edition some additions have been introduced—e.g., the polarisation of light and the

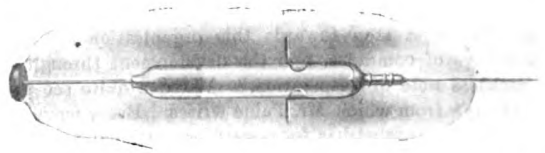
Roentgen rays, in accordance with recent advances upon the subjects, but it is disappointing to find no reference to the ionic theory of solution. In these days, when the dissociation theory has led to definite applications in medicine, we should expect to find in a comprehensive handbook a few words about it, more particularly as that book is intended for students of medicine. The illustrations are copious and well executed.——With a similar end in view, Mr. HUGH C. H. CANDY, B.A., B.Sc., F.I.C., has written his book, *A Manual of Physics* (London: Cassell and Co., Limited. Pp. 384. Price 6*s*. net). There is no attempt here to couple with physics the chemistry required by the Examining Board in the same volume. That is dealt with in *A Manual of Chemistry* by the same author, of which we have also taken a favourable view. The manual on physics bears evidence of the writer's practical acquaintance with the needs and opportunities of the medical student, for whom primarily it has been written. In spite of a fair sprinkling of mathematical formulas his account is not involved, and, of course, the student is intended to keep the manual by him when attending practical demonstrations, in which case it will aid his memory and understanding.——An eminently practical book is *Notes on Practical Physics*, by A. H. FISON, D.Sc. (London: Edward Arnold. Pp. 144. Price 3*s*. 6*d*.). The experimental directions are clear and concise, and the examples chosen form an excellent foundation for more elaborate work. His advice and suggestions are a model of sound teaching.——An interesting feature of *Elementary Experimental Chemistry*, by F. E. WESTON, B.Sc., F.C.S. (London: Longmans, Green, and Co. Pp. 140. Price 2*s*.), is the insertion of historical references to the chemical substances under experimental observation. We should like to see this plan in elementary text-books more general than it is, for there is a risk of losing sight of the early work of pioneers and of the time which has elapsed since this work was done. Mr. Weston's book contains a number of familiar experiments, and he has presented them in a wise order, so that the student begins with matters essential to the understanding of the final chapters.

The needs of those beginning their studies are again carefully studied in *Elementary Quantitative Analysis*, by F. M. OLDHAM, B.A. (London: Mills and Boon, Limited. Pp. 90. Price 1*s*. 6*d*.). The course in volumetric analysis (Part I.) and that in gravimetric analysis (Part II.) are well arranged and the directions are clearly outlined. We do not like the following expressions: "Calculate the weight of SO_4 in the barium sulphate and hence the percentage of SO_4 in the copper sulphate," or "in this way the weight of PO_4 ..... can be determined." SO_4 and PO_4 do not exist as separate entities and cannot be weighed. The method reminds us of an instruction (often found in text-books) such as the following: "Drop a small piece of K into a basin of H_2O," or "Put a small piece of P in a deflagrating spoon." The author has provided a simple working course of elementary quantitative analysis.——In *A Handbook of Organic Analysis*, by HANS THACKER CLARKE, B.Sc. Lond., A.I.C. (London: Edward Arnold. Pp. 264. Price 5*s*. net), we find a fairly wide field of organic substances covered. We quite agree with Dr. J. Norman Collie in the introduction which he has written to this book, that at the present time hardly any books exist which deal with the systematic testing of organic substances. Many there are which describe their preparation or give quantitative methods or deal with the special analysis of distinct classes of compounds, "but the book that would enable the chemist to find out qualitatively the nature of the multitudinous carbon derivatives met with in ordinary work in an organic laboratory—that book is wanted." The most valuable, as it is the biggest, section of this book is the one containing classified tables of common organic compounds. These tables will be of the greatest service to the chemist in his attempts to recognise unknown organic substances. The chapters on general matters are also good. Mr. Clarke's work is sure to be appreciated, and not the least because he has initiated an excellent movement to reduce the testing of organic substances to something like system and order.

New Inventions.

THE "HYPOSOL" AMPOULE SYRINGE.

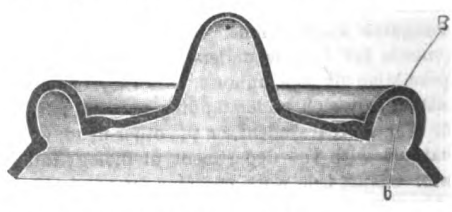
Messrs. Allen and Hanburys, of Lombard-street, London, E.C., have introduced a very ingenious form of ampoule syringe, which is intended to obviate most of the troubles and disadvantages incident to the subcutaneous injection of drugs. It is essential that the syringe, the needle, and the solution employed should be completely sterile; this is of the first importance, and usually no little time is taken up in preparing these for the injection. By the use of the ampoule syringe the greater part of this time is saved. A dose of the solution is contained in a sealed glass tube, which is drawn out at each end. In the tube at one end is a firm plug which acts as a piston. A sterilised needle is contained in a separate sealed glass tube. Before administering an



injection the two ends of the tube containing the solution are marked with a file and are then broken off. On one end of the tube which has been ground to a standard size the needle fits, and through the opening in the other passes a little rod, by means of which the piston is pushed down the tube, and in this way the injection is given with no risk of infection. Thus it is seen that the ampoule itself forms the syringe by which the solution is injected. The specimen tube sent to us worked quite satisfactorily, and the preparation occupied only a few seconds. The cost is by no means prohibitive. Most of the tubes of solution are supplied at 8*d*. each, but it must be remembered that the use of the ampoule syringe renders an ordinary syringe unnecessary, with its occasional need of repair. Vaccines prepared by the Lister Institute of Preventive Medicine can also be obtained in this form, but the cost is naturally higher.

A NIPPLE SHIELD.

THIS appliance, invented by Dr. A. Stern, is made of rubber and can be cleansed by boiling. Round the shield is a rubber margin forming an elevated circle (B) raised above the surface. In applying the shield the edges are drawn out so as to obliterate the raised portion, and as this tends to assume



its original form, on its doing so a vacuum is formed which keeps the shield tightly applied to the surface of the breast. The shield has been used by many obstetricians abroad, and is favourably reported upon. It is supplied by Messrs. A. Strauss-Collin, Bush-lane House, Cannon-street, London, E.C., and Frankfort-on-the-Maine.

THE LANCET.

LONDON: SATURDAY, MARCH 23, 1912.

The National Insurance Act: An Indictment.

DURING the past few months several books have appeared in explanation and defence of the National Insurance Act, and have been duly noticed in our columns. Some of these were obviously partisan from cover to cover, while others, accepting the Act with studied neutrality, set out to unravel its complicated provisions for the benefit of the public. These whitewashings and interpretations have, however, given small space to the real problems of "medical benefit," for their authors either failed to see, or chose not to see, that by its medical provisions a scheme of national health insurance must stand or fall. Of course, an immense amount of criticism of the medical provisions of the Act has appeared in our own columns and elsewhere in the medical and lay press during the past ten months, so that our readers are by this time familiar with the main arguments on which the medical profession relies for its objections to the Act in its present form. Nevertheless, there are many who will welcome a small volume, of which we have received advanced proofs, entitled "Can the Doctors Work the Insurance Act?"[1] They may agree with it all, they must agree with much of it, and they will have in their hands a compendium of the obvious objections which can be taken to the measure from a professional point of view.

The book is in essence a destructive criticism of the Act as it stands, disputing its present financial basis and controverting its spirit by supplying arguments in favour of payment for work done. It is intended to be a direct reply to the challenge of certain apologists of the Act who demanded information as to what is fair payment for medical services. The author declares that the profession will, and can, only work the Act upon the terms embodied in the "six cardinal points," to which he would add an essential corollary, "no *per capita* contracts whatever." He is in favour of national health insurance, provided always that the two interdependent conditions of adequate treatment for the patient and adequate payment for the medical men are guaranteed. The question he asks is not whether any medical men *will* work the Act as it stands, but "Can a doctor give adequate time and attention to his patient while earning a living for himself under the terms of the Act?" Mr. LOWRY naturally covers a good deal of ground which we have already gone over time after time, and many of his conclusions accord almost exactly with our own; but even so, he has a fresh way of putting familiar facts and well-worn arguments. He very wisely refrains from comment on the action taken by the leaders of the British Medical Association, or by their professional critics: these domestic matters he leaves altogether on one side, while throughout his vigorous pages he is careful to avoid unnecessary personalities.

He regards an income limit for those who would benefit under the Act as essential to the welfare of the profession. Only so long as the Act is limited to the struggling poor can the medical profession work it without irreparable injury to itself and to the public; he can see no necessity for extending the principle of compulsion in matters medical beyond the poor. He condemns the Act for imposing upon the medical man those very risks which the State itself has rejected, and he draws a sharp distinction between the club practice of the past and the State practice on a wholesale *per capita* system proposed by the framers of the Act. He abominates contract practice, and he maintains that such a system as that adopted for many years with success by the National Deposit Friendly Society would, if combined with an income limit, satisfy all the demands of the profession and guarantee adequate medical service without retarding the progress of scientific treatment. We do not intend to refer in further detail to Mr. LOWRY'S views. His style is rather controversial, and some of his figures and assumptions will scarcely escape challenge from those whom his irony touches; but on the whole he is on safe ground. His case, put briefly, is that the minimum demands of the medical profession are reasonable, and beneficent alike to profession and public; that these demands are not yet secured definitely; and that until they are so conceded the profession cannot work the Act in a manner consistent with its own honour or profit, or with due regard to the health of its patients. His volume supplies a closely reasoned answer to the oft-repeated question of the party politician, "Why should a profession which accepts 4*s.* with drugs reject 4*s.* 6*d.* without drugs?"

[1] Can the Doctors Work the Insurance Act? By E. W. Lowry, M.R.C.S. London: Watts and Co., 17, Johnson's-court, Fleet-street, E.C.

Surgery in the Middle Ages.

Mr. D'ARCY POWER has recently traced for us the evolution of the London surgeon[1] from the time of Master JOHN ARDERNE, "a gentleman at the most courtly and picturesque time of English history, when EDWARD III. was on the throne and the Order of the Garter had been recently established," down to Lord LISTER, who passed from among us but yesterday. The story of Master ARDERNE ("Master," because he was a master surgeon, entitled to wear the cap and gown of the guild or fraternity of surgeons of London, from which custom perhaps derives the English practice of styling all surgeons "Mr.," irrespective of degrees) is of great interest, for it shows us that even in mediæval times there were surgeons with a keen appreciation of what constitutes the basis of good surgery. Long prior to ARDERNE, indeed, in the thirteenth century, there were those who vigorously opposed the idea (prevalent even up to our own times) that pus in wounds was inevitable; who aimed at,

[1] The Evolution of the Surgeon in London. The Mid-sessional Address delivered at the Abernethian Society on Jan. 11th, 1912. St. Bartholomew's Hospital Journal, February, 1912.

and got, union by first intention; who practised drainage in suitable cases; and it is even stated induced anæsthesia by the inhalation of some volatile liquid—but here, it seems to us, we are greatly in the realms of fancy. ARDERNE himself unsparingly condemned the too prevalent practice of frequent dressing of wounds. Further, when others used caustics or ecraseurs, ARDERNE, who was by no means afraid of hæmorrhage, made clean incisions with a scalpel, stanching the bleeding with compresses, styptics, and the cautery. In those days of jousts and constant warfare, practice in the surgery of wounds must have been remarkably common, and involved, as Mr. POWER points out, not only good surgery but good nursing also. The nursing, he tells us, "was done by ladies, the wives, sisters, and sweethearts of the patients, who had been familiar from their youth upwards with the treatment of wounds, sword thrusts, and sprains, for the customs of the day gave ample opportunity of practising their skill, and all the romances of the time show them to have been excellent nurses." ARDERNE was a member of a knightly family of Saxon origin which was the first in England to adopt the Norman custom of a surname. He was born in 1307 and lived until nearly the end of the fourteenth century. He was educated at Montpellier University, and practised surgery for a while in France, but from 1349 until 1370 he practised at Newark-on-Trent. Finally, however, he yielded to the lure that even many modern provincial surgeons and physicians find so resistless, and removed to London.

Mr. POWER contents himself mainly with a picture of the ethical characteristics of ARDERNE'S times, and lays stress on the fact that ARDERNE was able to demand and obtain fees which, making due allowance for the purchasing power of money in those days as compared with our own, would make many a modern surgeon envious. In short, in the fourteenth century "the surgeon was able to hold his own with the best in the most chivalrous time and at the most courteous and extravagant court in Europe." According to another writer[2] who has made the field of mediæval medicine the subject of his own particular study, ARDERNE also used to keep case records, and was as proud of his statistics as any modern surgeon. Mr. POWER draws an outline of the attempt made in 1423 to combine the surgeons and physicians of London into one corporate body. He gives a brief account of WILLIAM CLOWES (1540–1604), a surgeon first in the army, then in the navy, who settled in London in 1569, and was appointed surgeon to St. Bartholomew's Hospital in 1575. But the wars again claimed him, and he served in the Low Countries in 1583 and in 1588 in the English fleet against the Spanish Armada. Mr. POWER quotes Dr. NORMAN MOORE'S estimate of CLOWES'S writings, that "they are the very best surgical writings of the Elizabethan age." He next refers to JOHN WOODALL (1569–1643), who inferred the efficacy of lime juice in scurvy from the happy accident of two ships' crews, one of which was smitten with scurvy, the other free from it, the conditions differing only in the fact that one had lime juice and the other had not. WOODALL published in 1617 the "Surgion's Mate," and in 1628 the "Viaticum, being the Pathway to the Surgion's Chest," text-books of surgery which long formed part of the library of every surgeon and surgeon's mate or assistant on sea or land. RICHARD WISEMAN (1621?–1676), like WOODALL, helped in the raising of surgery from a handicraft into a profession, and engaged in battle royal with quacks. Mr. POWER tells us that WISEMAN "differs from all his predecessors in his power of arguing from the particular case under discussion to a generalisation upon the principle involved." Into the stories of the later surgeons of whom Mr. POWER writes—WILLIAM CHESELDEN (1688–1752), PERCIVAL POTT (1714–1788), JOHN HUNTER (1728–1793), JOHN ABERNETHY (1764–1831), and greatest of all him whom we have so recently lost full of years and honours—Lord LISTER—we have not space to follow Mr. POWER, and, moreover, information concerning them is more generalised and more easily accessible. It would be well to study more closely the medical worthies of the Middle Ages, as far as possible in their own works and in the literature of their own times, for with their passing, it is daily becoming more and more likely, was engulfed a whole continent of potential knowledge.

[2] J. J. Walsh, M.D., Makers of Old Time Medicine.

The Nomenclature of Diseases.

SPEAKING precisely, there is no such thing as a disease. This truth has once more been forcibly enunciated by Sir CLIFFORD ALLBUTT, in an article on the Importance of Precision in Nomenclature,[1] in the following terms: "Diseases, then, are not things or 'entities,' but general concepts in our minds of various disorderly ways of function, swerving now this way, now that, in infinite variety, though on a larger view observing certain main lines of divergence and advance; so that for the convenience of thought, which is unable to grapple with things as wholes, we are enabled and are wont, not without a certain arbitrariness, to separate them into classes, and to form, for each class, a type, or mental ideal, ideals rarely realised in full, even in 'typical cases,' but which are standards to work by." The so-called names of diseases are, then, mere labels given to "a certain assemblage and succession of symptoms, normal and abnormal, recurring with fair uniformity." But in order to know what we are talking about in medicine it is clear that "we must use the names of these series respectively with the closest precision that conditions permit, although with no less clear a recognition of the arbitrary and provisional nature of our classification."

In consequence of a realisation of this truth efforts have been made from time to time to systematise the nomenclature of disease by drawing up tables of diseases. For this country the Royal College of Physicians of London has long undertaken this task. But in these days especially a progressive tendency towards internationalism is manifest, and in nothing more than in the medical sciences, for the essentials of man's structural organisation and functional activity are for the most part *humani generis totius*, and even the most marked racial or national characteristics affect little more than the surface. The need has thus made itself felt for a wider comparison of data than can be attained within the geographical boundaries of any one nation, however extensive,

[1] Universal Medical Record, vol. i., No. 1, January, 1912.

and the first essential for this international comparison is an international nomenclature. Hence arose the International List of Causes of Death, which, under the distinguished editorship of Dr. JACQUES BERTILLON, underwent its second decennial revision at Paris, July 1st to 3rd, 1909. The object of this List is to group together under the fewest possible headings the greatest possible number of more or less related causes of death. The necessity for such grouping lies in the fact that the number of possibly fatal diseases is so great that separate returns of each would be out of the question in tables showing the relation of cause of death to sex, age, locality, occupation, and other similar groupings. The numerical or hygienic importance of individual diseases, it is true, may require such tables to be made out for them individually in a few instances—e.g., bronchitis or plague—but for the most part a classification under group headings is essential.

The International List having been adopted as the basis of future registration in England and Wales, a manual[2] thereof has been recently published by the Registrar-General's office, which reflects great credit on Dr. T. H. C. STEVENSON, superintendent of statistics, by whom it has been prepared. It is intended to provide means for the compilation of mortality tables on an identical plan throughout the entire country, so that these may in future be truly comparable with each other, and also to supply the reader of the tables prepared by the Registrar-General with an opportunity of ascertaining as far as possible the precise significance of every item contained in them. With the assistance of Dr. ARTHUR NEWSHOLME an abbreviated list, while conforming to the International List, has been made identical with Skeleton Table III. issued by the Local Government Board to medical officers of health for their guidance in making their returns, and this coöperation, together with the adoption by the Registrar-General of the "Sanitary Area" as the geographical basis of tabulation, secures uniformity between the Registrar-General's statistics and the reports of the various medical officers of health. Frequent consultations with Dr. J. C. DUNLOP and Dr. NINIAN FALKINER, the statistical superintendents respectively of Scotland and Ireland, both of whom have approved the adoption of the International List, have also tended to further uniformity of the methods to be used throughout the United Kingdom. Moreover, Dr. CRESSY L. WILBUR, the distinguished chief statistician for vital statistics of the United States Census Bureau, in 1902 brought out for that bureau an American Manual, similar in scope to the one now under consideration; and the proof sheets of a new edition thereof, rendered necessary by the revision of the International List, were kindly placed at the disposal of Dr. STEVENSON. By this means a closer approximation in the practice of the two great English-speaking countries has been effected than would have been possible by the separate adhesion of both to the international system. It is to be regretted that circumstances prevented the adoption of a similar course with regard to Canada, Australia, and New Zealand; but as these countries adopted the International List before this country, the present step tends to uniformity.

A serious objection to the adoption of the International List lay in the disturbance of the continuity of English records necessarily attendant on the alteration of their basis of compilation; but this seems to have been successfully surmounted by a cross reference table showing the headings or titles used up to 1910 with numerical references to the corresponding headings or titles in the International List. Several other points of importance are dwelt on in the explanatory introduction of the manual—the rules in use in the General Register Office, England, for the selection of one from two or more jointly stated causes of death; a list of 200 indefinite or undesirable terms; an explanation of the terms "primary" and "secondary" causes of death as used in the death certificate, in which the former confusing definition of "primary" as first in order of appearance has been replaced by the more logical one of chief in importance; and the mode of registration of "transferable deaths"—i.e., deaths of persons who, having a fixed or usual residence in England or Wales, die in a district other than that in which they resided. In the adoption by the United Kingdom of the international system of mortality statistics an obvious advantage accrues through facility of comparison of English mortality with that of other countries; while Dr. STEVENSON by his adaptation of that system to this country has effected a great stride towards complete uniformity of registration throughout the United Kingdom and, indeed, all the chief English-speaking communities. It remains to be seen whether this undoubtedly great advantage and other incidental ones will be counterbalanced by the disadvantage adduced by Sir JOHN W. MOORE, and referred to in the special article on the manual in our issue of Feb. 24th (p. 528)—viz., that the transference to local affections of, for example, cerebro-spinal fever, pneumonia, epidemic diarrhœa, and puerperal fever from their rightful position under the heading of epidemic diseases places a formidable block in the path of sanitary reformers and medical officers of health.

[2] Manual of the International List of Causes of Death as Adapted for Use in England and Wales. Based on the second decennial revision by the International Commission, Paris, 1909. London: Published by His Majesty's Stationery Office. To be purchased either directly or through any bookseller from Wyman and Sons, Limited, Fetter-lane, E.C.; or Oliver and Boyd, Tweeddale-court, Edinburgh; or E. Ponsonby, Limited, 116, Grafton-street, Dublin. 1912. Pp. 128. Price 1s.

Annotations.

"Ne quid nimis."

THE STRIKE BILL.

THE measure introduced in the House of Commons on Tuesday by the Prime Minister is tentative. It is an emergency remedy, comparable (say) to opening an abscess, where the abscess is but the particular indication of some general condition, though the one that is producing the greatest disability in the patient. The keenest faculties of diagnosis are called for in those who have charge of our body politic, and the country will expect in the consultant practitioners to whom the therapeutic course is entrusted the exhaustive care and absence of party or personal prejudice which can alone make the methods of treatment trustworthy. But appearances are against the discussion of the measure with this calmness, and the existing symptoms are urgent.

THE ATTEMPT ON KING VICTOR EMANUEL'S LIFE.

THE civilised world, without a dissentient voice, has proclaimed its horror at the attempted assassination of the King of Italy and its congratulation with His Majesty and His Majesty's subjects on his providential escape. The attempt itself has nothing to distinguish it from others of the kind, all too familiar as those have been to the former generation and to the present. A degenerate creature, one of the type in whom microcephalism is a concomitant, if not, indeed, a condition precedent, of megalomania, has, it would appear, been told off by an anarchist camarilla to "save society" and to earn the martyr's crown by assassinating the head of the State; and he plays his part accordingly, with the due observance of traditional detail. He selects the place and the time of his attempt with an eye to that publicity which is supposed to make it most impressive, and he fires a succession of shots at his august victim in the full light of day and in the city's chief thoroughfare. He fails in his purpose, wounding only a member of the Royal escort, and he incurs the immediate attentions of the indignant crowd, whose wish to lynch him he well knows will be frustrated by the very authority against which he is a declared rebel. He is further gratified by the consciousness that, for the day, he is the one theme of conversation at home and abroad, and he awaits his trial with the serenity of one who knows that on that occasion the interest in him will be revived, till he receives the penalty which at worst will leave him the life he tried to take from another. Have we not here, in Antonio d'Alba, a replica of the Passanantes, the Casserios, the Angiolillis, the Luchenis, the Brescis, who have maintained for Italy in regicide the sinister priority she has long held in homicide? How she is to break that unenviable record may well employ the time and the thought of her best public men, many of whom see in it not only the outcome of idiosyncrasy, ethnological and national, but of tradition in the family and in the State. There is no doubt, as Italy's great criminologist, Baron Garofalo, has pointed out, that vendetta has a place in social life peculiar to the Latin races in general and to the Italian in particular; that it has acquired something of the force of a pious obligation, transmitted from father to son, an obligation fostered, if not justified, by absolute distrust in the integrity of the law, and stimulated by the unconstitutional promoters of Italy's "Risorgimento." Of this last concurrent cause of vendetta as an institution, it is freely admitted that the gospel of the "stiletto morale" (the moral dagger) as preached by the burning eloquence of Mazzini, has been a powerful coefficient, all the more powerful from the lofty *morale* of the man, from his patriotic ideal, from his whole life—sacrificing as he did, according to Carlyle, one of the grandest literary careers of the nineteenth century to the work of underhand, sometimes underground, plotting against the prevailing order. In his famous letter to a brother revolutionist, Daniel Manin, he glorified the knife of Timoleon, the dagger of Brutus, the arrow of Tell, the stone of Balilla, and the poniard of Palafox, in language all too effective with his compatriots, uninstructed and even illiterate as the majority of these were, investing their impulse towards lethal methods with a moral sanction that seemed to justify them on the most slender provocation. In the prisons set apart for homicides undergoing life sentences the inmates are often found to have their bodies, generally their forearms, tattooed with mottoes taken from the revolutionary vocabulary, mottoes which ring the changes on the rubric under which the anarchist societies to which the said inmates belonged march in procession on gala days: "Né Dio, né Padrone" (neither God nor Master). Such is the moral atmosphere from under which an Antonio d'Alba has emerged like all his counterparts, aye, and will continue to emerge till Italy's appalling percentage of "analfabeti" is reduced from thousands to units. In furthering the movement and the methods antagonistic to this "analfabetismo" no man has taken a more enlightened, a more devoted, a more self-sacrificing part than the true disciple of Cavour and scion of the House of Savoy who has just escaped the anarchist's vendetta, and the spontaneous, the universal outburst of indignation at the attempt and of joy at its failure attests the soundness of the national sentiment if undepraved by ignorance or unperverted by vindictive agitation. "Ha tirato contro l'Italia" (he fired against Italy) was the exclammation of her great poet, Giovanni Pascoli, on hearing of d'Alba's deed. Let us hope that Italy, from the Alps to Etna, will so respond to that sentiment as to renew with redoubled effort her educative propaganda so often postponed to that of political interests in which those of the people are forgotten, if not lost.

FEEBLE-MINDEDNESS AND THE MEASUREMENT OF THE INTELLIGENCE BY THE METHOD OF BINET AND SIMON.

WE publish on another page of this issue a valuable communication by Dr. W. C. Sullivan, medical officer in H.M. Prison Service, on a new method of estimating degrees of feeble-mindedness, devised some time ago by M. Binet and M. Simon. The method was originally intended to be applied as a gauge of intellectual development in normal children, but its wider applicability can be readily realised by perusal of Dr. Sullivan's article. Absence of any suitable and practical standard whereby to estimate degrees of intellectual impairment in children and young adults has always been a stumbling block in the way of scientific advance towards a solution of the problem of the feeble-minded. Where criteria are wanting, the question as to what constitutes feeble-mindedness remains unanswerable. It is true that the physician with experience soon learns to distinguish approximately the *arriéré* from the normal child, but individuals differ in their interpretation of what is within physiological limits and what is outside, and unanimity on the matter has never been attained. The definition of feeble-mindedness supplied by the Royal College of Physicians of London to the Royal Commission on the Control and Care of the Feeble-minded, as Dr. Sullivan justly points out, is based on empirical data and is of little value as an aid to diagnosis; indeed, this was not the intention of its originators. The tendency of scientific research is ever in the direction of reducing general expressions to their lowest terms, of testing phenomena by the application of some fundamental rule or rules to the circumstances under which they appear—in a word, of standardising data so that comparisons and contrasts may be accurately drawn. That such scientific principles should be applied to the problem of the backward child is a sign of advance. The scale devised by M. Binet and M. Simon is based on extensive observations on French school children at various ages, and may be taken to represent average attainments of average children at any given age. It is a kind of examination in general knowledge, and in it theoretical considerations are avoided as far as possible. If some such scale of intellectual attainment were utilised by preceptors, and more particularly by physicians whose interests are with backward children, it is clear that a great step would be taken towards the obtaining of those data on which alone a scientific definition of feeble-mindedness can be based. It is noteworthy that for each age five tests are arranged, so that the results can be expressed in figures, and however artificial they may appear, as

Dr. Sullivan himself states, without some accepted convention of this description the classification of a child as feeble-minded or otherwise will still depend to a certain extent on the whim of the examining physician. Dr. Sullivan has applied the method with interesting and suggestive results to the juvenile offender. An excellent opportunity for its application might be found in the case of young epileptics, who are often mischievous, restless, inattentive, spiteful, cruel. But are they really feeble-minded? The criteria of M. Binet and M. Simon might well be utilised in this connexion. There is, also, the very large class of backward children, using the term in a general sense, who do not present any sign of physical disease; anxiety for their welfare and interest in their development lead the parents to seek medical opinion on the possibility of these children being able to earn their living, and the physician would be in a better position to formulate a reasonably accurate prognosis if he had the results of systematised mental tests at hand. Of course, the chief difficulty, as Dr. Sullivan is fully aware, is that the individuals to whom these tests may be applicable are often characterised not so much by mental inferiority as mental inequality. Intelligence involves many factors. Many children possess faculties abnormally developed with others that are in abeyance. It is rare to find equality in maldevelopment on the part of all the factors that combine to form a child's mental "make-up." It is notoriously otherwise. Sometimes memory is extraordinarily acute. There used to be a patient in one of the county asylums who could enumerate all the occasions on which any given member of the institution had played tennis. We have heard of a youthful diplegic whose memory for dates was prodigious, though in other respects he was a typical *arriéré*. Dr. John Kerr, late H.M. Inspector of Schools for Scotland, has recorded in a recent volume of reminiscences the case of a child who could tell on what day of the week any day of the whole year, or of several years preceding, fell, by some mental process of which we have at present no clear conception. Cases of this kind are no doubt exceptional, but the fact remains that the physician will, as a rule, have to deal with a mind unequally developed, not uniformly inferior. Now we note that in Binet and Simon's scale not a few of the tests are pure tests of memory—e.g., in the case of the 15 year children two, if not three, are pure memory tests, out of five—and it may be questioned whether some modification in this respect may not be desirable. In this connexion, however, it is proper to note that Dr. Sullivan considers the scale should not be held to be final, and experience will soon remedy any defects which it may possess. The main argument is that some convention is necessary, and the plea which Dr. Sullivan has advanced for the adoption of the principle we cordially endorse.

AMŒBIC DYSENTERY IN GREAT BRITAIN.

THE use of the term "tropical" as a synonym for amœbic dysentery sufficiently indicates the prevalent view that this form of intestinal infection is only met with in tropical countries; nevertheless, cases have been reported from time to time as occurring in European countries, and even Great Britain. An instance of this nature is reported in the current number of the *Edinburgh Medical Journal* by Major D. G. Marshall, I.M.S., in the case of a ploughman who had never been out of Scotland. The disease had apparently existed for seven weeks before he was admitted for treatment at the Royal Infirmary, Edinburgh, the symptoms being increasing diarrhœa, with slimy stools containing "whitish specks like pieces of mutton fat." The appearance of blood in the motions had been a late occurrence, but was present after admission. Amœbæ were found on examination, but no bacilli of the "Flexner" type could be cultivated. Treatment consisted in the administration of powdered ipecacuanha in doses of from 20 to 30 grs. and rectal lavage with solution of quinine. Recovery ensued after one relapse. The origin of the infection in this case was obscure. It was suggested that the patient might have contracted the disease from a time-expired soldier from India, who lived near by, through the medium of infected drinking water, the abnormally high temperatures prevalent during the summer of 1911 having enabled the organisms to exist outside the body. The alternative possibility that the ordinary harmless amœbæ of the bowel may, under certain conditions, take on pathogenic properties cannot be entirely discarded in view of the defective state of our knowledge of the life-history and specific characters of different amœbæ; but all the evidence at present available seems to support the distinction drawn by Schaudinn between the innocuous Entamœba coli and the pathogenic Entamœba histolytica.

SHYNESS.

ALTHOUGH shyness, like egotism, may be said to arise from a pathological degree of self-consciousness, the presence of this elusive and illogical failing in an otherwise normal individual is by no means easy to explain; and if we are to judge by the way in which they ignore the subject, the psychologists find no less difficulty in its definition and classification. They are content, for the most part, to include it under the headings of "shame" and "modesty" in their analysis of the emotions, but this is by no means satisfactory. Shyness is, psychologically, much more nearly related to fear than to shame. That it does not necessarily proceed from even a sense of moral, mental, or physical deficiency, still less from the actual existence of these, is well known, and it is this fact that makes the curious predilection of the malady for certain individuals one of its most aggravating features. Speaking broadly, we may say that shyness consists essentially in a state of morbid self-consciousness of one's personal characteristics, whether physical or mental, in relation to the opinions of others. There is a certain amount of evidence to show that shyness is hereditary; but however this may be, it is largely a matter of temperament in individuals and finds a fruitful ally in a too active imagination. It is as protean as influenza in the forms in which it betrays its presence, and may exhibit itself in a thousand little gaucheries which in extreme cases may render the life of its unhappy possessor a burden to him. "Sins may be forgiven," said Nathaniel Hawthorne—himself a victim to shyness—"but shyness has no forgiveness in heaven or earth." Not infrequently the malady takes the form of excessive rudeness, with the result, it may be, that the most gentle and kind of characters is shunned at all costs as a boor. It may literally paralyse movement and speech. There has been recorded the case of an excessively shy man who, in reply to the toast of his health at a dinner given in his honour, went over his carefully prepared speech in pantomimic gesture only. This dread affliction is no respecter of persons. Charles Matthews, Garrick, and Byron were instances of men who suffered from shyness in their relations to the social life of their time, and there is a well-known author-dramatist of to-day who, it is understood, suffers tortures from the disease. Sir Isaac Newton was morbidly shy, and had an objection to the publication of his discoveries lest it should lead to an increase in the number of his acquaintances. The late Prince Consort was terribly shy. It has been remarked, and with some truth, that this extraordinary affliction is largely confined to the Teutonic races, and Georges Sand humorously attributed the Englishman's stiffness and awkwardness, especially when travelling abroad, to what she called the

"fluide Britannique," which she averred he carried about with him in self protection. As a national characteristic, however, this abnormal aloofness and shyness has its compensations. It throws a man more upon his own resources; society ceases to be a necessity to him, and this may have been one of the reasons of the Anglo-Saxon's supremacy as a pioneer in the untrodden regions of the earth. Those with a more intense social instinct have been less successful colonisers. Shyness has its compensations as a racial characteristic.

THE PEST-HOLE OF THE PACIFIC.

THE term "pest-hole of the Pacific" is applied by some American writers to Guayaquil, the main seaport of Ecuador, situated on the western coast of South America, not much more than 800 miles by sea from the Panama Canal. Another name applied to Guayaquil in recent years is "the clearing-house of the western hemisphere for cholera, yellow fever, small-pox, and bubonic plague"; and by yet others it is known as "the plague-spot of the west coast of South America." From all accounts this evil reputation is not altogether undeserved. Yellow fever, for example, has for a long time been endemic, giving rise now and again to virulent epidemics. During the last three years, according to consular reports, more than 1000 persons have been attacked in the town by this disease. Plague also for some years has been constantly appearing, and in the period 1909–11 no fewer than 2424 attacks have come under official observation. Small-pox, too, is of frequent occurrence, and severe outbreaks occur at comparatively short intervals. Though Guayaquil possesses one of the finest harbours to be met with along the whole coast of the Pacific, its sanitary circumstances leave a great deal to be desired. A large section of the poorer population are idle and apathetic, their habits are filthy, and their squalid homes are infested by rats, fleas, and other vermin, while in the neglected spaces around these dwellings the yellow fever mosquito finds many favourable breeding places in which it multiplies exceedingly. In anticipation of the opening of the Isthmian Canal at no very distant date, public opinion in the United States is becoming somewhat uneasy as to the outlook, and this has found expression of late in the lay and medical press. In THE LANCET of Feb. 10th we discussed the possibility of the Panama Canal facilitating the diffusion of exotic disease, particularly yellow fever and plague. Our contemporary, the *Journal of the American Medical Association*, in its issue of Feb. 17th, draws attention to the danger that may be expected to arise for the United States from certain South American States, more especially Ecuador, when the new commercial water-way is opened for traffic. The article is headed "What is Sauce for the Ecuador Goose is Sauce for the American Eagle," and it is pointed out that as all civilised nations now forbid the use of dum-dum bullets, submarine mines in peaceful harbours, or floating torpedoes in the track of commerce, therefore in the same way the export of yellow fever, cholera-polluted drinking-water, or disease-transmitting insects such as might be carried by ship from one port to another should similarly be forbidden by all advanced nations. On the other hand, if the right of the United States Government to intervene with the view of compelling Ecuador to place the sanitation and administration of Guayaquil on a proper footing is admitted, there would be nothing to prevent the Italian Government from insisting that the city of Pittsburg, for example, should be forced to provide uncontaminated drinking-water for the many Italian workmen employed in the steel mills of that city; or to prevent the Russian Government from putting pressure on the United States to "clean up" the tuberculosis-breeding tenements of Greater New York, in which every year thousands of Russians cough away their lives. Such procedure would be in line with the march of civilisation, but attended with many difficulties. If the United States forced Ecuador to "clean up" its one main seaport, ought not the former first of all to put its own house in order by "cleaning up" some of the backward cities in its own territory, where each year thousands of deaths occur from preventable causes? In the *New York Medical Record* of Feb. 17th attention is also directed to the subject of the danger arising from Guayaquil's unhealthy condition. Referring to a despatch which stated that yellow fever was increasing and threatening to become severely epidemic in Guayaquil, it is mentioned that General Plaza, who quelled the recent revolution in Ecuador, had been attacked by the disease. Our readers may remember that not long ago one of the assistant surgeons of the United States Public Health and Marine Hospital Service, who was attached to the Consulate-General at Guayaquil, contracted yellow fever, from which he died in a few days. The public departments of the United States concerned with the subject, as also the officials of the Panama Canal Zone, have offered their aid to the Government of Ecuador to carry out the necessary sanitary reforms at Guayaquil, but with what result we do not know. It is, perhaps, a favourable indication of advancing public opinion that Ecuador was represented at the International Sanitary Conference which assembled last November in Paris. The delegates should be in no doubt as to what is needed to satisfy international requirements, and we have no doubt that having this knowledge in their possession any courteous and diplomatic representations made by the Government of the United States would meet with a satisfactory answer. Before long we may see the unenviable notoriety of Guayaquil removed, when it will be no longer appropriate to apply to Guayaquil the opprobrious epithet of "the pest-hole of the Pacific," but Ecuador, judging from recent occurrences, is plunged in barbarism, and not much can be hoped for from the initiative of its leading men.

PRESENTATIONS TO PROFESSOR P. W. LATHAM.

THE occasion of the departure from Cambridge of Dr. P. W. Latham, who for 20 years held the chair of the Downing Professorship of Medicine, has been used by his many friends to testify their warm esteem of himself and Mrs. Latham personally, as well as their sense of the value of his public work. A meeting was held in the Combination Room of Gonville and Caius College on Thursday, March 14th, for the purpose of making a presentation to Professor Latham. The presentation, consisting of a pair of silver entrée dishes and a parchment scroll containing the subscribers' names, had been subscribed for by the medical men of Cambridge and district and other medical friends. A large meeting was presided over by Sir T. Clifford Allbutt, who in a very interesting speech spoke of Professor Latham's distinguished career since the time they were undergraduates together at Caius. Mr. N. Beverley, of Norwich, and Professor Sims Woodhead also spoke to the value of Professor Latham's work in a professional and scientific regard. On Friday evening, March 15th, at Trinity Hall, presentations were made to Professor Latham and his wife. To Mrs. Latham was presented a diamond pendant brooch, and to Professor Latham a piece of plate suitably inscribed. The Master of Trinity Hall, Mr. E. A. Beck, presided over the meeting, and the Master of Peterhouse made the presentation. In so doing he spoke of the high esteem in which Professor Latham was held as physician, of his brilliant career as a student, of his great work for Addenbrooke's Hospital, and of his services to the University, particularly as Downing Professor of Medicine for 20 years. Professor Latham will carry with him into his well-earned retirement the good wishes not only of a large

circle of private and professional friends, but of several generations of students at the School of Medicine in Cambridge, which during the term of his professoriate made such remarkable strides forward.

SUNSHINE AND RAINFALL FOR 1911.

* A day with rain is one on which at least 0·01 in. was measured.

The large excess of sunshine which was one of the chief features of a remarkable year was for the most part due to the unusually fine summer, but over a considerable portion of the kingdom nearly every month added something to the plus value. At several of the southern resorts the aggregate number of hours was more than 2100, the highest figures being 2142 hours at Bournemouth, 2146 at Felixstowe, 2147 at Hastings, and 2158 at Eastbourne. In the north-west, Blackpool recorded 434 hours more than the average, a greater excess than at Eastbourne. At Tunbridge Wells the excess amounted to 442 hours, and at Westminster as much as 448 hours. Westminster was, relatively to its average, the most sunny spot in the whole kingdom. It will be seen that the City of London received many more hours of sunshine than Birmingham, Manchester, Newcastle-on-Tyne, and Glasgow, and rather more than York; it was, however, less sunny than Nottingham and Sheffield. Fort Augustus, owing mainly to the adjacent mountains shading the valley, was the least sunny spot, while the place where smoke and dust formed the chief obstacle to the sun's rays was Newcastle. The total rainfall for the year was not everywhere less than the average, the great deficiency of the first nine months having been made up by the heavy and frequent rains of the last three. This was especially the case in the south-east of England, where Tunbridge Wells finished with the large excess of 5·6 in. The greatest deficiency was in the Midlands and some parts of East Anglia. The metropolis as a whole received rather less rain than during an average year, and a portion of it, Tottenham, had rain on fewer days than any other part of the kingdom. Although the total fall at Tottenham and Hampstead was practically identical, the latter had a measurable quantity on 29 more days than the former. Next to Tottenham the fewest rain days occurred at Clacton and Brighton, but in many other places over the southern half of England the figure was nearly as low. All the above information has been compiled from a summary of the year's weather published by the Meteorological Office.

THE POISONS SCHEDULE.

IN the exercise of its powers under the Pharmacy Acts the Council of the Pharmaceutical Society has declared in a resolution, passed at its March meeting, that certain alterations ought to be made in the Poisons Schedule—namely (*a*) that sulphonal be removed from Part II. of the Schedule to the Poisons and Pharmacy Act, 1908, and that "sulphonal, its derivatives, and the poisonous derivatives of mercaptol" be substituted therefor, and (*b*) that "diethyl-barbituric acid and other derivatives of barbituric acid, and all poisonous ureides and their derivatives," ought to be deemed poisonous within the meaning of the Pharmacy Acts, and ought to be added to Part II. of the Schedule to the Poisons and Pharmacy Act, 1908. The resolution has been submitted for the approval of the Privy Council, and if such approval be given the resolution and approval will be advertised in the *London Gazette*, and on the expiration of one month from such advertisement the articles named will be deemed to be poisons within the meaning of the Pharmacy Acts. There have been occasions on which the Privy Council has not given its approval of resolutions declaring that certain substances ought to be deemed poisons, but apparently there is nothing to lead to the supposition that its approval will be withheld on this occasion. The reasons which have decided the Privy Council to refuse to assent to the scheduling of certain substances in the past cannot be applied in the case of veronal and its derivatives, for the extent to which the trade interests in these compounds is likely to suffer cannot be considerable when compared with the greater degree of safety which will be ensured by surrounding the sale of these articles with precautionary restrictions of an elementary character. If and when the compounds indicated in the resolution are included in the Poisons Schedule, their sale by retail will be

confined to registered pharmacists, who will be required to label the packages in which they are sold with the word "poison" and the name and address of the seller. With the exception of sulphonal, any of the drugs in question may be sold, at the present time, without any restriction whatever, and in the absence of the poison label there is nothing to impress upon the mind of the purchaser that he is handling dangerous substances. In some countries it is illegal for any person to sell these and many other compounds except to persons for whom they have been prescribed by a medical practitioner, and if such a regulation could be made and enforced in our own country so much the better would it be for the public; unfortunately, however, our pharmacy laws do not provide for any restrictions of this kind, and in the meantime we must be satisfied with such protection as is afforded by the poison label and the discretion of the pharmacist. The best known compounds which will be brought into the Schedule, if the consent of the Privy Council is given to the resolution, are trional and tetronal (as poisonous derivatives of mercaptol), and veronal, malourea, malonal, and hypnogen, but the proposed "additions" are so worded as to include any like substances of the same series which may subsequently be introduced into materia medica.

JOHN BELLERS.

IT is well known that Lister belonged by birth to the Society of Friends, and this religious community has added other less splendid names to the golden book of medicine and medical reform. One of the earliest is that of John Bellers, a Gloucestershire squire and Quaker philanthropist, whose "Essay towards the Improvement of Physick, in Twelve Proposals," published in 1714, was prophetic as well as practical. It is one of some 18 works, each of which is remarkable for originality and benevolence of outlook. Taking the 12 proposals seriatim, we are at once faced by an adumbration of the hospital system of the present. Bellers, indeed, was one of the first to propose the building of many hospitals in London and elsewhere. Those in or near London were to be for the benefit of the poor, and were, if possible, to be devoted to different "capital distempers." Two were certainly to be devoted to the blind and to incurables. Registers of cases were to be kept and human dissection was to be practised. The incurables were even to furnish live material for experimentation. It is quaintly proposed that "any person may have the liberty to give medicines to such incurable patients as are willing to follow their prescriptions. And such as make any cure, should be rewarded by the State, if the patient is not able to do it. And after many repeated cures of such patients, a gratuity should be given by the Government to the owner of such medicines to make a public discovery of them. And if he desires it, to be placed as a physitian in one of the hospitals where his medicine is proper." Thus the loss of some good medicines would be prevented. It was further proposed that a public laboratory and "physical observatory" should be provided to prepare all medicines used in physic and to conduct researches for the discovery of new remedies. Bellers's "Seventh Proposal" is aptly prophetic. It is proposed that "in every Hundred of a County, and Parish of a City, there be appointed one Doctor and Chirurgeon (or more, if needful) to take care of the sick poor in them; who should visit every parish once a week, at least. And they to be paid by the overseers of the poor: and such whose illness may be chronical, especially if declared to be incurable, they should be sent to the most suitable hospital." There was to be a State control of drugs which would make against quackery. Thus, it was proposed that all "published medicines" were to be examined "with the greatest candor and exactness that possible may be." Public notice of a good medicine was to be given "that the owner may be encouraged," and bad drugs were to be publicly notified as such. Other proposals of much interest are in favour of the endowment of research by various bodies and in various forms. Finally, it is proposed that the London College of Physicians and Company of Surgeons act as practical advisory bodies to practitioners, at that time very ignorant, and that every session a Committee of the Houses of Parliament be reported to by these bodies on the state of medicine. John Bellers was not only before his own time but before our time.

THE CHEMISTRY OF THE BOOT.

THE use of materials as innocent as can possibly be is a reasonable requirement in regard to the clothes we wear, since, of course, they are not merely decorative but are essential to the well-being and comfort of the body. The boot, in particular, is trusted to protect a part of the body peculiarly sensitive to damp and cold, and quality in boots is very desirable in the interests of the general health. Yet probably there are fewer articles showing wider variations of quality than leather. Good leather is a boon, but bad leather a snare. It is, therefore, somewhat disturbing to find that a whole laboratory of chemicals may occur in the boot. Not a few people have found after a hard day's work or exercise that their socks are stained a deep yellow derived from the chromates used, amongst other things, to give a rich tone to the leather. Chromates are poisonous salts. There may be other mineral substances present which are not so easily disclosed in a domestic way, but which readily appear on analysis. Thus may be found salts of lead, tin, aluminium, iron, and even the glucose which is used to assist in the preparation of the leather from the hide, but which, perhaps intentionally, has escaped elimination. It is reasonable to suppose that all these things are used for a specific purpose, but we may be sure that good sound material does not require the presence of such foreign substances. Leather made to look good by tinkering cannot fulfil so effectively the high hygienic purpose of the genuine unadulterated article. Brown paper is an innocent article enough, but it discounts terribly the best properties of the sole of the boot, which can only be satisfactorily waterproof and protective against cold when it consists of good pure leather. The subject is one which might attract more attention at the hands of our hygienic authorities than it appears so far to have done.

EPIGASTRIC HERNIA A CAUSE OF CHRONIC DIARRHŒA.

WITHIN the past few years a good deal has been written and published in the medical journals relating to epigastric herniæ, "small protrusions, usually not larger than a walnut, situated in the linea alba between the umbilicus and the xiphoid cartilage," in the words of Dr. Farrar Cobb, of Boston, Massachusetts, writing in the *Annals of Surgery* for March. They are commoner in males than females, and usually contain omentum, less often transverse colon. Any symptoms that are present are apparently due to adhesions between the hernial sac and the parietal peritoneum or neighbouring viscera; they are usually gastric in character. Dr. Cobb, however, reports a case in which the symptoms were intestinal, and says he was unable to find any other such record in medical literature. His patient was a tanner, 69 years old, whose chief symptom was diarrhœa of seven months' duration. From six to 14 loose watery motions were discharged daily, almost without remission, during this period. Blood had not been passed. His weight had diminished by

nearly 40 pounds. He had had six months of hospital treatment, both in the wards and in the out-patient department, and taken all kinds of drugs, and submitted himself to every conceivable dietary, but nothing had effected any real improvement. Physical examination had discovered no cause for the diarrhœa until Dr. Cobb noted the presence of an irreducible epigastric hernia. In default of any alternative, this was regarded as a possible cause of the symptoms and an operation accordingly decided upon. The contents of the sac proved to be omentum firmly adherent to the peritoneum of the abdominal wall as well as to that of the sac itself, and fastening the transverse colon to the anterior abdominal wall. The sac was extirpated and the adhesions divided so as to set the colon free. The patient recovered satisfactorily from the operation and has had no more diarrhœa, so that it seems reasonable to ascribe the whole trouble to irritation of the colon by adhesions. The possibility of such a cause should therefore be borne in mind in dealing with cases of intractable intestinal flux.

COLONIAL PHARMACISTS AND RECIPROCAL AGREEMENTS.

THE Privy Council has approved a by-law made by the Council of the Pharmaceutical Society of Great Britain which empowers the society's council to enter into reciprocal agreements with colonial pharmaceutical authorities for the admission to the Register of Chemists and Druggists, without examination, of persons who, after approved courses of study and examination, have become registered in any British colony as entitled to carry on the business of a chemist and druggist in that colony. Draft regulations have been prepared by the council in consultation with representatives of Colonial Pharmacy Boards, which, it is suggested, might form the basis for reciprocal agreements. These provide that every applicant should produce evidence (1) of having passed a preliminary examination of such a character as to be a guarantee of a sound preliminary educational training; (2) of having been trained in a chemist's shop, for at least three years, in the translation and dispensing of prescriptions; and (3) of having passed, after systematic study, a qualifying examination, practically equal in scope and standard to the examination of the Pharmaceutical Society of Great Britain. The British qualifying certificate is already accepted for registration in lieu of examination in most parts of the Empire, but hitherto the Canadian Pharmacy Boards have refused to accept it on the ground that their certificates are not recognised in this country. Now that the new by-law is confirmed the Pharmaceutical Society will, for the first time, be in a position to register Canadian and other colonial pharmacists without examination.

THE NATURE AND TREATMENT OF DIABETES.

IN another column we publish an article on the Dietetic Treatment of Diabetes by Dr. P. J. Cammidge, whilst in THE LANCET of Feb. 24th and March 2nd and 9th, we published the Lettsomian lectures delivered before the Medical Society of London by Dr. Archibald E. Garrod on Glycosuria. The former, as its title indicates, deals mainly with therapeutics, whilst the latter is chiefly concerned with theoretical and pathological considerations. Dr. Garrod draws attention to many morbid conditions which bring about disturbances of the metabolism of carbohydrates, and also points out that such disturbances manifest themselves in several different ways. He also reviews the pathogeny of diabetes, and shows that in some cases the nervous system is at fault, and that in others the thyroid, the pituitary, or the pancreas is the seat of the disease, but he expresses the opinion generally held that in the majority of cases encountered in practice no indications are found of the underlying lesion upon which the metabolic derangement depends. With regard to treatment, Dr. Garrod refers to the efficacy of restriction of diet, which has ameliorated the lot and prolonged the lives of hosts of sufferers from diabetes; he admits, however, that it is essentially a symptomatic therapy based on the fact that it is the metabolic derangement which proves fatal to so many patients. He further argues that until more is known of the conditions that underlie the diabetic syndrome a more radical method of treatment cannot be determined on. Dr. Cammidge's, therefore, is a suitable supplement to Dr. Garrod's lectures, for, disregarding the questions which have not yet been definitely answered as regards the origin of the disease, he explains at length a rational method of overcoming the metabolic derangement. The basis of his method is not new—namely, that the aim of modern treatment is to balance the diet in such a way that nutrition is as perfect as possible without there being an unnecessary strain on the organs of metabolism in any direction. One point, however, particularly merits the attention of practitioners—namely, that it is not sufficient merely to give a patient lists of foods which he may take and avoid, but he must be instructed in how much of each permitted food he may, and must, take to keep up the supply of energy he requires. A study of Dr. Garrod's remarks and the suggestions as to the required dietary made by Dr. Cammidge will yield much valuable information as to the present state of knowledge in regard to the nature and treatment of diabetes.

AT the adjourned annual clinical debate of the Chelsea Clinical Society on March 19th, Professor Wilhelm Einthoven, M.D., of Leyden, read a paper on the Various Forms of the Human Electro-cardiogram and their Significance, which will be published in THE LANCET.

THE King and Queen on March 16th paid a surprise visit to Guy's Hospital, where they were received by Lord Goschen, treasurer, and Sir Cooper Perry, medical superintendent.

BRISTOL GENERAL HOSPITAL.—The eightieth annual meeting was held on March 11th at the hospital, the Lord Mayor of Bristol being in the chair, and supported by the Bishop of Bristol, Mr. Joseph Storrs Fry, president and treasurer, and Mr. Herbert M. Baker, chairman of committee. The report was on the whole satisfactory. The work done reached a record height. The in-patients numbered 2787, an excess of 136 over 1910, and the out-patients 40,578, an advance of 535. The in-patient figures have increased by 29 per cent. in five years, and the average stay of each in-patient during 1911 was 23·5 days only. It is no exaggeration to say that the hospital has been quite full, almost without respite, for several years, so that the projected extensions are urgently necessary. The ordinary receipts were £11,524, or £547 less than in 1910; this was due to a falling off in donations, which is fully accounted for by the fact that during the past year the Bristol public gave nearly £45,000 for the wing about to be built. The ordinary expenditure reached £15,320, the increase of £563 over last year being entirely accounted for by new and increased salaries. Legacies amounting to £6625 were received, the committee being able to invest about £3700. There is a balance due to the treasurer of £2052. Other points of interest in the report were an allusion to the effects of the Insurance Act, pointing out that the work of the hospital would scarcely be touched by the establishment of the new medical service, so that diminution of the subscription list is sincerely to be deprecated; the impending retirement after three years' excellent service of the senior resident, Mr. C. A. Moore, who will, however, be still connected with the hospital in an honorary capacity; and the beginning of the new wing, the site for which is being rapidly cleared. Mr. Mervyn King, vice-president, said that in 30 years' experience he had never known the work of the hospital so efficiently done as at present.

CRAWFORD WILLIAMSON LONG, THE PIONEER OF ANÆSTHESIA.

BY DUDLEY W. BUXTON, M.D., B.S., M.R.C.P.,
ANÆSTHETIST TO UNIVERSITY COLLEGE HOSPITAL AND LECTURER ON ANÆSTHETICS IN UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

(Concluded from p. 673.)

Statement of Dr. Long.

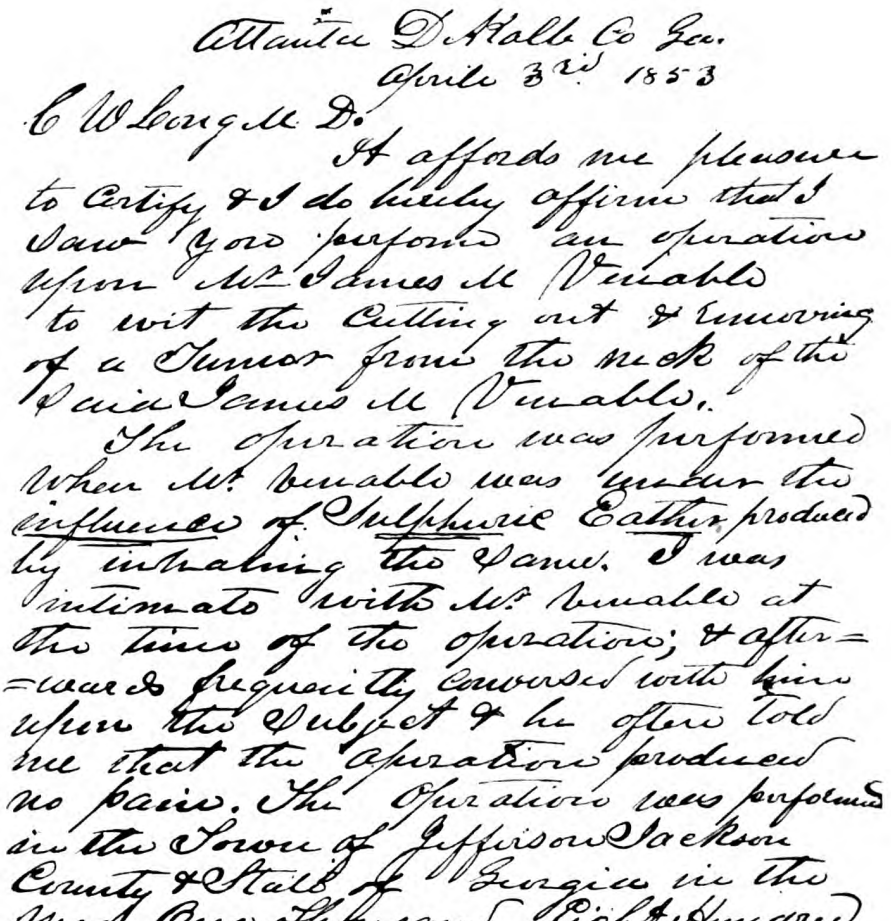
THE following statement made by Dr. C. W. Long in 1849 to the Medical Society of Georgia[1] is of great interest:—

For nearly three years the various medical journals have contained numerous articles on the employment of sulphuric ether by inhalation, for the purpose of rendering patients insensible to pain during surgical operations.

I was interrupted when I had written but a few lines and was prevented by a very laborious country practice from resuming my communication until the *Medical Examiner* for January, 1847, was received, which reached me in a few days after reading the December number. It contained several articles, giving accounts of different experiments in etherisation, in which surgical operations were performed without pain. On reading these articles I determined to wait for a few months before publishing an account of my discovery, and see whether any surgeon would present a claim to having used ether by inhalation in surgical operations prior to the time it was used by me.

A controversy soon ensued between Messrs. Jackson, Morton and Wells, in regard to who was entitled to the honour of being the discoverer of the anæsthetic powers of ether, and a considerable time elapsed before I was able to ascertain the exact period when the first operations were performed. Ascertaining this fact, through negligence I have now permitted a much longer time to elapse than I designed, or than my professional friends with whom I had consulted advised: but as no account has been published (so far as I have been able to ascertain) of the inhalation of ether being used to prevent pain in surgical operations as early as March, 1842, my friends think I would be doing myself injustice not to notify my brethren of the medical profession of my priority of the use of ether by inhalation in surgical practice.

FIG. 4.



Atlanta DeKalb Co Geo.

C W Long M. D.

It affords me pleasure to certify & I do hereby affirm that I saw You perform an operation upon Mr James M Venable to wit the Cutting out & removing of a Tumor from the neck of the said James M Venable.

The operation was performed when Mr Venable was under the influence of Sulphuric Aether produced by inhaling the same. I was intimate with Mr Venable at the time of the operation; & afterwards frequently conversed with him upon the Subject & he often told me that the operation produced no pain. The operation was performed in the Town of Jefferson Jackson County & State of Georgia in the Year One Thousand Eight Hundred & Forty Two. Yours &c.

W. H. Thurmond.

The first notice I saw of the use of ether, or rather of Dr. Morton's "Letheon," as an anæsthetic, was in the editorial of the *Medical Examiner* for December, 1846, in which the editor gives the following extract from a paper by Dr. H. J. Bigelow, contained in the *Boston Journal*. "The preparation (Letheon) is inhaled from a small two-necked glass globe, and smells of ether, and is, we have little doubt, an ethereal solution of some narcotic substance."

Having on several occasions used ether since March, 1842, to prevent pain in surgical operations, immediately after reading this notice of "Letheon" I commenced a communication to the editor of the *Medical Examiner* for publication in that journal to notify the medical profession that sulphuric ether when inhaled would of itself render surgical operations painless, and that it had been used by me for that purpose for more than four years.

[1] This and copies of other documents were added as protocols to this original paper, but are not reproduced in the present article.

I know that my interests have suffered from not making an earlier publication, and I would not be persuaded at this late stage of the ether controversy to present my claim to being the first to use ether as an anæsthetic in surgical operations, if I were not fully satisfied of my ability to establish its justness.

Account of First Two Operations.

Then follows Dr. Long's statement setting forth the chain of reasoning which led him to employ ether as an anæsthetic. We have already quoted this. Long continues:—

The first patient to whom I administered ether in a surgical operation was Mr. James M. Venable, who then resided within two miles of Jefferson, and at present lives in Cobb County, Georgia. Mr. Venable consulted me on several occasions in regard to the propriety of removing two small tumours situated on the back of his neck, but

would postpone from time to time having the operations performed from dread of pain. At length I mentioned to him the fact of my receiving bruises while under the influence of the vapour of ether without suffering, and as I knew him to be fond of and accustomed to inhale ether, I suggested to him the probability that the operations might be performed without pain, and proposed operating on him while under its influence. He consented to have one tumour removed, and the operation was performed the same evening. The ether was given to Mr. Venable on a towel, and when fully under its influence I extirpated the tumour. It was encysted and about half an inch in diameter. The patient continued to inhale ether during the time of the operation, and when informed it was over seemed incredulous until the tumour was shown him. He gave no evidence of suffering during the operation, and assured me after it was over that he did not experience the slightest degree of pain from its performance. This operation was performed on March 30th, 1842.

The second operation I performed upon a patient etherised was on June 6th, 1842, and was on the same person for the removal of another small tumour. This operation required more time than the first, from the case of the tumour having formed adhesions to the surrounding parts. The patient was insensible to pain during the operation, until the last attachment of the cyst was separated, when he exhibited

Georgia
Jackson County } I D. F. Hinton Clerk of the Superior Courts of said County do certify that the above account is a Correct Copy of an original entry made in this Book for Medical services for the year 1842.

Given under my hand & seal of office this 2nd day of March 1849.
D. F. Hinton, Clerk S.C.J.C.

signs of slight suffering, but asserted after the operation was over that the sensation of pain was so slight as scarcely to be perceived. In this operation the inhalation of ether ceased before the first incision was made. Since that time I have invariably directed patients, when practicable, to continue its inhalation during the time of the operation.

Having so long neglected presenting my claim to the discovery of the anæsthetic power of ether, for the purpose of satisfying the minds of all of its justness, I have procured, I conceive, a sufficient number of certificates to establish the claim indisputably.

In Long's paper appear certificates from some of his patients as well as from eye-witnesses of the operation. Fig. 4 is a fac-simile of one of these.

Other Operations.

My third experiment in etherisation was made on July 3rd, 1842, and was on a negro boy, the property of Mrs. S. Hemphill, who resides nine miles from Jefferson. The boy had a disease of a toe, which rendered its amputation necessary, and the operation was performed without the boy evincing the least sign of pain. I present Mrs. Hemphill's statement of the report the boy gave her of the operation on his return home, which I conceive is sufficient on this point.

These were all the surgical operations performed by me during the year 1842, upon patients etherised, no other case occurring in which I believed the inhalation of ether applicable. Since 1842 I have performed one or more surgical operations annually on patients in a state of etherisation.

The question will no doubt occur, Why did I not publish the results of my experiments in etherisation soon after they were made? I was anxious, before making my publication, to try etherisation in a sufficient number of cases to satisfy my mind that anæsthesia was produced by the ether, and was not the effect of the imagination or owing to any insusceptibility to pain in the persons experimented upon.

At the time I was experimenting with ether there were physicians, high in authority and of justly distinguished character, who were the advocates of mesmerism, and recommended the induction of the mesmeric state as adequate to prevent pain in surgical operations. Notwithstanding thus sanctioned, I was an unbeliever in the science, and of the opinion that if the mesmeric state could be produced at all it was only on those of "strong imagination and weak minds," and was to be ascribed solely to the workings of the patients' imaginations. Entertaining this opinion, I was the more particular in my experiments in etherisation.

Surgical operations are not of frequent occurrence in a country practice, and especially in the practice of a young physician, yet I was fortunate enough to meet with two cases in which I could satisfactorily test the anæsthetic powers of each. From one of these patients I removed three tumours the same day. The inhalation of ether was used only in the second operation, and was effectual in preventing pain, while the patient suffered severely from the extirpation of the other tumours. In the other case I amputated two fingers of a negro boy. The boy was etherised during one amputation and not during the other; he suffered during one operation and was insensible during the other.

I have procured the certificates of the lady from whom the tumours were removed and of her husband, who was present and witnessed the

operations. These certificates were produced in preference to those establishing other operations, because they not only show that the experiments were continued from year to year, but also show that they were conducted so as to test the power of etherisation.

After fully satisfying myself of the power of ether to produce anæsthesia, I was desirous of administering it in a severer surgical operation than any I had performed. In my practice, prior to the published account of the use of ether as an anæsthetic, I had no opportunity of experimenting with it in a capital operation, my cases being confined, with one exception, to the extirpation of small tumours and the amputation of fingers and toes.

I have stated that ether was frequently inhaled in this and some of the adjoining counties for its exhilarating effects, and although I am conscious that I do not deserve any credit for introducing its use for that purpose, yet as others through their friends have claimed to be the first to show its safety, most of the certificates I have obtained establish the fact of its frequent inhalation for its exhilarating effects. I met with R. H. Goodman, who was present the night ether was first inhaled in Jefferson, and who removed to Athens, and introduced its inhalation in that place, and presented his certificate. All the young gentlemen who were present the night I first administered ether, with one exception, are living, and their certificates can be procured, if necessary.

I have now, in a very concise manner, presented a "plain unvarnished" account of some of my experiments in etherisation, and have said nothing of the comparative methods of ether, and other anæsthetics, because that was foreign to my present subject. Had I been engaged in the practise of my profession in a city where surgical operations were performed daily, the discovery would, no doubt, have been confided to others, who would have assisted in the experiments, but occupying a different position, I acted differently, whether justifiable or not. The result of my second experiment in etherisation was such as to lead me to believe that the anæsthetic state was of such short duration that ether could only be applicable in cases in which its effects could be kept up, by constant inhalation, during the time of the performance of the operation. Under this impression, up to January, 1847, I had not used ether, but in one case, in extracting teeth, and thus deprived myself of experimenting in the only class of cases which are of frequent occurrence in a country practice.

While cautiously experimenting with ether, as cases occurred, with a view of fully testing its anæsthetic powers, and its applicability to severe as well as minor surgical operations, others more favourably situated engaged in similar experiments, and consequently the publication of etherisation did not "bide my time." This being the case, I leave it with an enlightened medical profession to say whether or not my claim to the discovery of etherisation is forfeited, by not being presented earlier, and with the decision which may be made I shall be content.

The fac-simile of the original entry in Dr. Long's account-book of his charge made to the first patient, J. M. Venable, possesses interest (see Fig 5).

Ether, 1842–1911.

The narrative given by Long of his first administration of ether to a patient in 1842, that by Morton, which is more detailed, referring to his demonstration of the effects of Letheon on a patient in the Massachusetts General Hospital (1846), and that given in great detail of the first ether operation performed in a London hospital—viz., University College Hospital—when Liston operated, reveal the fact that very little was known about anæsthetics and less about methods. In the one case a towel was employed, in the other two a primitive inhaler, consisting of an ether chamber and a series of tubes connecting it with a face-piece.

After Simpson introduced chloroform at the end of 1847, ether, at all events in this country, was neglected in favour of the newer claimant, chloroform. The perils of the latter incident to the methods adopted in its exhibition soon led to fresh attempts being made to employ ether or some mixture of it and chloroform. The committee of the Royal Medical and Chirurgical Society in its report published in 1864 extolled ether's safety, but pointed out as its inherent drawback that the induction of anæsthesia by it was too slow for convenience. Then came the rational attempts of Clover, Ormsby, and many more to remove this disability by the use of closed inhalers. No practical attempt was, however, made to study a percentage method for etherisation. The very safety of the drug became its chiefest danger, since etherists were so obsessed by the fact that ether does not lower blood pressure or cause cardiac collapse through depression, that they failed to recognise the perils incident to over-stimulation, especially in asthenic persons. The dangers of post-operative chest troubles were not existent in the pioneer days of ether because the operations performed were comparatively brief and the surgeons taught in pre-anæsthetic days prided themselves on their celerity in operating, and, indeed, were appraised by the public for this quality. To-day there is no haste, the advance of surgery has invaded the regions once immune from the knife; if ether is adopted for this wider range of operations it is necessary that methods of using it must follow on other than the traditional lines. To safeguard against excessive dosage we rely on mixed methods, such as the preliminary hypodermic injection of scopolamine, morphine, and atropine; we adopt an open mask, evaporating from an enormously expanded area provided by many folds of gauze, and so obtain a more complete nebulation of our vapour; we introduce ether directly into the blood-stream in an artificial circulating fluid of physiological saline solution by intravenous infusion, with the hope of maintaining an equable and low-grade partial saturation of the neural tissue. In every case, we must remark, the supreme difference consists in the fact that we have replaced a method of excessive dosing by one of moderation and in most instances capable of rapid variation in the strength of ether employed. We have been too overborne by *a priori* reasoning, too obedient to traditional authority. Whether our newer methods may not introduce fresh dangers we cannot as yet say; if they do it will be probably because our technique is at fault, and this must be amended. It is startling when we think of the early workers to find the modern etherist safely and easily encompass anæsthesia with ether for tongue or jaw operations. Yet such is the case. By the intratracheal insufflation method now so efficiently carried out in America we find ether conveyed into the lungs without the inconveniences formerly incident to the method of introducing ether by oral inspiration. The experience gained gives promise of even more efficient plans of using ether, of saving life, and enabling the modern surgeon to perform his tasks, often almost daunting in their complexity and difficulty, without the added anxiety of an anæsthesia either imperilling the patient's life or necessarily imperfect owing to the patient's reaction towards the drug employed. If Long's work was the first step towards what we have achieved to-day, and it was so, to him we owe this much that we do his memory great and abiding honour. But we must realise, also, that anæsthesia to-day is on its trial, it must advance and trample on tradition and rely upon experiment unless we are content to forsake the hope of founding a science, and are willing to content ourselves with a mere handicraftsman's place in the ranks of the medical profession.

I desire to express my thanks to Mrs. Long Taylor, through whose kindness I have been furnished with documentary evidence of the accuracy of the facts I have advanced about her father, Crawford W. Long; also to Dr. George Foy, of Dublin, to whose unique knowledge of this matter and collection of memorials of Crawford Long I have been most generously made welcome.

THE FINAL REPORT OF THE ROYAL COMMISSION ON VIVISECTION.

THIS long expected report has been reviewed in general terms already in our columns, but more detailed notice of it is due to our readers.

Since the Royal Commission on Vivisection was appointed on Sept. 17th, 1906, two of the Commissioners, Lord Selby (chairman) and Mr. John Tomkinson, have died. Mr. Tomkinson was not replaced, and Mr. A. J. Ram, K.C., succeeded Lord Selby in the chairmanship. The other surviving Commissioners are Colonel Lockwood, Sir William Selby Church, Sir William J. Collins, Sir John McFadyean, Sir Mackenzie Dalzell Chalmers, Dr. W. H. Gaskell, and Dr. George Wilson. The secretary, Captain Clive Bigham, retained his office throughout the inquiry.

The instructions to the Commissioners were: "To inquire into and report upon the practice of subjecting live animals to experiments, whether by vivisection or otherwise; and also to inquire into the law relating to the practice and its administration, and to report whether any, and if so what, changes are desirable." In carrying out their instructions the Commission held more than 70 meetings and examined a large number of witnesses, including representatives of the Royal Colleges of Physicians and Surgeons, and of the Royal Society, prominent exponents of medical research, representatives of antivivisection societies, and ministers of religion. They also considered papers from various official, medical, scientific, and other sources, bearing on the questions before them. They naturally consider, therefore, that the evidence before them has informed them concerning every class of opinion on the subject. The report as a whole is signed by every surviving member of the Commission; but Colonel Lockwood, Sir William Collins, and Dr. George Wilson append a memorandum of eight pages containing certain

reservations, to which Dr. Wilson adds a further memorandum of no less than 65 pages, as against the 64 pages of the report itself.

SUMMARY OF REPORT.

We cannot do better than consider the report in the same order and subdivisions as are adopted by the Commissioners. These are: 1. The administration of the Act of 1876; the powers and practice of the Home Office in relation thereto; and an examination of certain specific and general charges brought against the office in regard to its administration of the Act. 2. Questions relating to the whole subject of animal experimentation—viz., (*a*) the progress of medical science in connexion with animal experimentation, with the result of such experiments in regard to the prevention and cure of disease and the advance of physiological knowledge; (*b*) the question of pain and anæsthesia; and (*c*) the moral question as to the justifiability of such experiments. The Commissioners finally consider some of the suggestions made to them and submit certain recommendations.

The Administration of the Act.

After briefly recounting the history of legislation against cruelty to animals up to the Antivivisection Act of 1876, with a summary of the provisions of that Act and a brief comment on the status of legislation on the subject in the British Colonies and foreign countries, the Commissioners proceed to consider the administration of the Act in Great Britain in respect of the various certificates licensing places or persons for the performance of experiments; the relations of the Home Office to the Association for the Advancement of Medicine by Research; the duties of inspectors; records, reports, and returns; and the administration of the Act in Ireland. They next deal with the criticisms of certain persons, foremost among which is an indictment of 12 counts by Mr. Stephen Coleridge. Mr. Coleridge began each count with the formula: "I am here to charge the Home Office officials." It is unnecessary to detail these charges—further than to say that they all accuse the Home Office, as the authority appointed to control the working of the Act, of grave dereliction in the performance of its duties—because, after a most careful, impartial, and thorough examination of each of the 12 charges, the Commissioners state:—

These twelve charges of Mr. Coleridge's are the outcome of a ten years' investigation of the Administration of the Act by the Department, conducted by an acute and indefatigable critic supported, as he told us, with ample funds. We have indicated the points in which we think that the administration of the Home Office may be open to criticism, but we are of opinion that, on the whole, the working of the Act has been performed with a desire faithfully to carry out the objects which its framers had in view.

Miss Lind-af-Hageby's charges, as formulated in a book (written in collaboration with Miss Schartau), "The Shambles of Science," are next considered. Her most sensational charges, that of the rabbit placed in a freezing-box, and of the marmot alleged to have had its spinal cord severed, are forbearingly described as "founded on a misapprehension." In like manner the allegations of Mrs. Cook, Lieutenant-Colonel Lawrie, and Mr. J. W. Graham are conclusively shown to be mistaken. Concluding this part of their report the Commissioners state that:—

After careful consideration of the above cases we have come to the conclusion that the witnesses have either misapprehended or inaccurately described the facts of the experiments.

Then follows this clause, significant, indeed, in view of the unanimous signature of the report:—

So far as we can judge we believe that holders of licences and certificates, with rare exceptions, have endeavoured with loyalty and good faith to conform to the provisions of the law.

We desire further to state that the harrowing descriptions and illustrations of operations inflicted on animals, which are freely circulated by post, advertisement, or otherwise, are in many cases calculated to mislead the public, so far as they suggest that the animals in question were not under an anæsthetic. To represent that animals subjected to experiments in this country are wantonly tortured would, in our opinion, be absolutely false.

The Progress of Science and Results of Experiments on Animals.

The report now states that:—

The sciences of physiology and pathology on which the progress of medicine and surgery mainly depends have been built up partly by observation and partly by experiment. Inasmuch as the subject matter of physiology is living things, the question naturally arises as to whether that science is not *à priori* likely to be advanced by experiments on living animals, and it is necessary to inquire whether, in fact, the history of physiology does or does not show that it has been thus advanced.

In the course of this inquiry, after a consideration in general terms of "The Influence of Experiment on the Advance of Physiology as a Pure Science," and "Physiological Discoveries which are stated to have been of Immediate Advantage in the Practice of Medicine and Surgery," the Commissioners consider in detail the evidence submitted to them in proof of: (1) The Benefits to the Practice of Medicine Claimed as the Result of Experiments on Living Animals; and (2) the Advances in the Practice of Surgery Claimed as the Result of Experiments on Living Animals.

It is stated that "the practice of medicine depends on physiology—the science of the normal functions of the body—on pathology—the science of disease—and on pharmacology and therapeutics—the sciences of the action of drugs, &c., in health and disease. Witnesses of eminence and experience have testified to the necessity of experimentation on animals in building up these basic sciences." The value of experimentation has been shown by the establishment of accurate indications for the administration of previously known drugs—e.g., digitalis in heart disease; the introduction of new drugs (all drugs introduced within the past 40 years, with the single exception of pilocarpine, being due to animal experimentation), soporifics (chloral, sulphonal, veronal), local anæsthetics (cocaine, eucaine, stovaine), analgesics and antipyretics (antipyrine, antifebrin, phenacetin, exalgin), physostigmine, nitrites in angina pectoris, diuretics (caffeine, theobromine, diuretin), and urinary disinfectants (urotropine), and finally for the standardisation of certain drugs.

Antiseptic and aseptic surgery.—In reference to the attempts that have been made to discredit the immortal work of Lister, the report, after detailing the history of his researches, says:—

Certain witnesses have emphasised the distinction between the antiseptic and the aseptic methods, and have pointed out that the late Mr. Lawson Tait and others successfully used what is now known as the aseptic method at a time when most surgeons were using the antiseptic method, but both methods are clearly traceable to the recognition of the need of cleanliness in surgery, and neither can be dissociated from the work of Lord Lister, as founded on Pasteur's researches on the origin of putrefaction and septic disease.

Anæsthesia.—While admitting that "the discovery of anæsthetics owes nothing to experiments on animals," the report is careful to point out that "thousands of experiments have, however, been made on animals with a view to elucidate the mode of action and the methods of preventing danger from the use of anæsthetics." Reference is also made to the introduction of the subcutaneous and intraspinal injections of local anæsthetics as due to animal experiments.

Improvement in technique.—The report quotes largely in this connexion from Sir Henry Morris's evidence referring to the localisation of the motor centres in relation to brain abscess, tumours, and injuries, the removal of the gall-bladder and of the larynx, nephrectomy, and intestinal operations, and from Sir Victor Horsley's evidence referring to the last named. Reference is also made to Lord Lister's researches on ligatures, and to Sir H. Swanzy's evidence on animal experiments in relation to ophthalmic surgery.

Infectious diseases in general are next dealt with, special attention being given to the evidence of Sir John Simon; then the relations of tuberculosis, plague, cholera and typhoid, malaria, yellow fever, sleeping sickness, diphtheria, and scarlet fever, tetanus, dysentery, Mediterranean fever, and snake poison are discussed severally in detail. The relation of experimental research to the work of the public health authorities is reviewed, and finally, its bearing on the diseases of animals themselves. They point out that of recent years the value of the experimental method has been very largely recognised by the public at large as well as by various public bodies, and cite particularly—

1. The foundation of Schools of Tropical Medicine, subsidised by the Colonial Office and Colonial Governments, and the appointment of research expeditions or commissions to investigate on the spot such diseases as sleeping sickness, plague, malaria, Malta fever, &c.
2. The foundation of an Imperial Research Fund for the purpose of investigating cancer.
3. The appointment of a Royal Commission to investigate by experimental methods and otherwise that great scourge to the human race, tuberculosis.

This part of the report ends with the following conclusions:—

We have received evidence from persons eminent in physiological, pathological, and sanitary science who have testified to their belief that knowledge has been acquired in regard to the vital functions, the causes

of disease, and also in regard to means for their prevention and cure which, in their opinion, but for such experiments, could not have been acquired. We have, on the other hand, heard many witnesses, some of them having medical qualifications, who have disputed that valuable knowledge has been obtained by such experiments, maintaining that this knowledge has been erroneously attributed to such experiments, or who have contended that success has not attended the application of the knowledge to the preventive or curative treatment of disease.

Having regard to the witnesses who have appeared before us and to the evidence which we have received, there can be no doubt that the great preponderance of medical and scientific authority is against the opponents of vivisection. This is more markedly so now than was the case before the Royal Commission of 1875.

On these questions, and apart altogether from the moral and ethical questions involved in the employment of experiments on living animals for scientific purposes, we are, after full consideration, led to think: (1) That certain results, claimed from time to time to have been proved by experiments upon living animals and alleged to have been beneficial in preventing or curing disease, have, on further investigation and experience, been found to be fallacious or useless. (2) That, notwithstanding such failures, valuable knowledge has been acquired in regard to physiological processes and the causation of disease, and that useful methods for the prevention, cure, and treatment of certain diseases have resulted from experimental investigations upon living animals. (3) That, as far as we can judge, it is highly improbable that without experiments made on animals mankind would at the present time have been in possession of such knowledge. (4) That, in so far as disease has been successfully prevented or its mortality reduced, suffering has been diminished in man and in lower animals. (5) That there is ground for believing that similar methods of investigation if pursued in the future will be attended with similar results.

Pain and Anæsthesia.

In this section the Commissioners discuss the question how far immunity from pain in experiments on animals is, or can be, secured. They enter into the meaning of "incomplete anæsthesia"; they discuss "movements other than reflex movements, purposive movements, struggling, and vocal cries as occurring under anæsthesia and yet not in their [i.e., scientific witnesses'] opinion indicative of any suffering, since in the case of man these are found on recovery to have been either unconscious or unassociated with any painful recollections." They consider general anæsthetics, "pithing," the use of morphia, curare, and conclude that—

After careful consideration of the whole question of anæsthetics as applied to experimental investigations on living animals, we are led to the conclusion that by the use of one or other or of a combination of several well-known anæsthetics complete insensibility to pain can be secured.

In regard to inoculations, they consider that—

From the foregoing conclusions it is clear that although in the large majority of experiments performed under Certificate A (which dispenses with the use of anæsthetics) the animals do not appear to suffer pain, it is also clear that, even if the initial procedure in cases under that certificate may be regarded as trivial, the subsequent results of this procedure must in some cases, at any rate, be productive of great pain and much suffering.

In their recommendations they deal with the additional safeguards which in their opinion should be applied to inoculated animals as well as to animals operated on.

The Moral Question.

On the question whether, and how far, the objection taken by some that such experiments are morally wrong and unjustifiable can be sustained, the opinions (for of course this question is purely a matter of opinion, not of fact) of Mrs. Cook, Miss Arabella Kenealy, L.R.C.P., Mr. James Graham, M.A., the Rev. J. Page Hopps, Sir George Kekewich, Miss Lind-af-Hageby, the Rev. L. S. Lewis, Dr. G. H. Burford, Mr. Stephen Coleridge, Mr. John Hughes, Dr. C. R. J. A. Swan, Mr. R. J. M. Cowen, L.R.C.P. & S. Irel., Mr. A. G. Scott, Sir F. Banbury, Bart., M.P., and Mr. J. H. Levy were taken on the antivivisection side; while Lord Rayleigh, Lord Justice Fletcher Moulton, F.R.S., Sir Victor Horsley, and incidentally many of the other scientific witnesses, were heard on the side of science. It is satisfactory to find the Commission's conclusion on this point clearly and emphatically stated in the following terms:—

After full consideration we are led to the conclusion that experiments upon animals, adequately safeguarded by law, faithfully administered, are morally justifiable and should not be prohibited by legislation.

As regards the different classes of animals used for experiments and the possibility of making discrimination between them for such purpose ..... there can be ltle doubt that the general moral sense of civilised mankind would be prepared to make such differentiation. ..... The *differentia* in such case would probably be found to consist in the degree of association with, or of affinity or utility to, man.

..... Thus we think that the higher apes (anthropoid) and the dog and cat present claims for special consideration, and with these claims we deal subsequently in our report.

Recommendations.

The Commissioners next review "various practical suggestions" put before them, directed to amending the law at present governing animal experiments, and after repeating that notwithstanding adverse criticisms the Act, in their opinion, "has nevertheless been so worked as to secure a large degree of protection to animals subject to experiment, and at the same time so as not to hamper or impede research," submit recommendations which we may summarise as follows:—

1. An increase in the number of inspectors, either a chief inspector and three inspectors for Great Britain, all whole-time officials, in place of existing arrangements; or an additional number of part-time inspectors who could give such time to their duties as would be equivalent to the services of four whole-time men. In Ireland sufficient inspection could be obtained by the services of one or more part-time inspectors. They further recommend the limitation as far as possible of licences to those places which are in connexion with universities or other public authorities or institutions.
2. Entire prohibition of the use of curare, or the presence of an inspector throughout the experiment who should satisfy himself that complete anæsthesia is maintained until death.
3. They cannot recommend any alteration of the existing law in relation to experiments for attaining manual skill.
4. They conclude that the production of sera and vaccines for commercial purposes ought not to be brought within the provisions of the Act.
5. As regards the exclusion of certain classes of animals, the majority agree that if any alteration in the existing procedure be made "the special enactments now applicable to horses, asses, and mules might be extended to dogs and also to cats and anthropoid apes."
6. In "pithing" "no lesser operation than a complete destruction of the brain or decapitation should be accepted as equivalent to complete anæsthesia, and in a warm-blooded animal it should be conducted only by a licensed person, and the operation itself should be performed under an adequate anæsthetic."
7. The Commissioners, "having regard to the limited knowledge which at present obtains as to the capacity of suffering" in cold-blooded animals, cannot recommend their exemption from the Act.
8. No change in the present system with regard to licences and certificates is necessary or desirable, but no certificate should be available until the applicant has received notice that it has not been disallowed by the Secretary of State. The existing practice is endorsed of granting licences and certificates to foreigners on condition that the experiments should be done only under the superintendence of the responsible head of some particular laboratory, and the restriction should be attached to all licences and certificates granted to foreigners.
9. The following additional safeguards against pain are recommended to be attached to certificates:—(1) That an inspector should have power to order the painless destruction of any animal which, having been the subject of any experiment, shows signs of obvious suffering or considerable pain, even though the object of the experiment may not have been attained; and (2) that in all cases in which, in the opinion of the experimenter, the animal is suffering severe pain which is likely to endure, it shall be his duty to cause its painless death, even though the object of the experiment has not been attained.

The Commissioners add:—

We regret that we cannot recommend any further extension of the "pain condition." We are anxious, as far as possible, to prevent or to limit animal suffering in every case. We have recommended that there should be increased inspection, that wide powers should be given to inspectors to order the painless destruction of any animal under experiment, and that in future, although the object of the experiment has not been attained, no animal should be allowed to live in severe pain which is likely to endure. But we do not feel justified in recommending that, when the object of the experiment has not been attained, an experimenter should in all cases be required to destroy the animal immediately it exhibits signs even of severe pain, which might in some cases be only momentary.

We are satisfied by the evidence that in the great majority of the experiments under the Act the animals do not exhibit any symptoms suggestive of severe pain, and to require the immediate destruction of an animal as soon as it exhibits such symptoms might, in our opinion, put an insuperable obstacle in the way of investigating many widespread diseases (afflicting both men and domesticated animals) with respect to which further knowledge as to their nature and treatment is in the interest of humanity urgently required.

It must not be forgotten that it is in the case of diseases which are naturally painful when they attack men or animals that experiments are most likely to involve pain to animals which are experimentally infected; as examples we may instance cancer, cholera, plague, tetanus, rabies, and snake bite.

We are compelled to accept the weighty evidence given before us to the effect that the study of animals experimentally infected with some of these diseases has given us knowledge which has been instrumental in saving much mortality and suffering both in man and animals, and we believe that discoveries already made in this way justify the hope that by the same methods knowledge may yet be extended regarding the means of preventing or curing other most painful diseases which are at present scarcely or not at all amenable to treatment. And finally we feel that as long as public opinion sanctions the infliction on animals of pain, which is not only severe but of long duration, in the pursuit of sport, and in carrying out such operations as castration and spaying, or in the destruction of rabbits and of rats and other vermin by traps and painful poisons, it would be inconsistent and unreasonable to go further than we have already gone in limiting experiments which are designed to result and, according to experience, will probably result in preventing or alleviating great human or animal suffering.

THE MINORITY RESERVATION.

In a Reservation Memorandum Colonel Lockwood, Sir William Collins, and Dr. Wilson say:—

The two main points upon which we dissent from the report are firstly as to securing by Statute that undivided responsibility of the Secretary of State which was recommended by the previous Royal Commission, but which the Act of 1876 failed to establish, and secondly as to placing a statutory requirement upon an experimenter painlessly to destroy an

animal which has been experimented upon when obvious suffering has supervened. Both points lead up to and in our opinion necessitate amendments of the law.

They consider the weight of evidence opposed to the view, that only administrative modifications are required in order to give effect to the changes which experience proves to be desirable, and they doubt whether the changes recommended can be adequately carried out without legislation. They think that "the distinction between *Licences—granted by the Secretary of State* and subject to all the restrictions in the Act, chiefly for the protection of animals, and *Certificates—granted by the Scientific Authorities* which waive the aforesaid restrictions—needs to be accentuated."

They sum up the fundamental principles upon which any special legislation should be based as follows:—

1. That all investigations upon living animals of an experimental nature by way of operation, inoculation, or infection, &c., shall only be conducted under the sanction and undivided responsibility of the Secretary of State, aided by skilled advisers, and exercising control and supervision by an adequate staff of inspectors.
2. That all such investigations which, in the absence of anæsthesia would be likely to cause pain or suffering, shall be conducted under adequate anæsthetics, skilfully and humanely administered, or if the nature of the investigation render this impracticable, then that on the supervention of real or obvious suffering, the animal shall be forthwith painlessly killed.

DR. WILSON'S RESERVATION MEMORANDUM.

Dr. Wilson, in his additional reservation memorandum, regrets that permanently impaired health and seriously impaired eyesight had prevented him from rendering assistance in the preparation of the first draft of the report. While he is in general agreement with the principal findings and recommendations of the Commission he cannot fully endorse all the opinions and conclusions which it embodies without qualification or supplement. Agreeing that with very few exceptions the specific instances of infringement of the Act as investigated have not been proved, he makes the following very significant admission:—

> For I am free to confess that, like a great many others, I was somewhat ignorant of the manifold safeguards provided under the Act for the prevention of needless pain, and as a continuous and close reader of the medical journals in which many of these experiments are published, I was often horrified with the details and entertained grave doubts as to whether such severe and prolonged operations could be performed under anæsthesia so complete as to abolish all consciousness of pain.

He recommends that inasmuch as compliance with the Act cannot be ensured, but must always mainly rest on the care, ability, and honest endeavour of the licensee, every licensee should append to his report of experiments performed a certificate that the experiments "have been conducted in strict compliance with the provisions of the Act to the best of his endeavour and belief." While he agrees that the great weight of the evidence before the Commission "is overwhelmingly in favour of the conclusion that valuable results have been obtained from experiments on animals," he does so in only a very restricted sense; he has been "far more impressed with the fallacies and failures which have attended this method of research." He suggests that "experimental physiology necessitating other than cold-blooded animals for demonstration should only be taught as part of post-graduate courses to fully qualified medical men who intend to pursue physiological research work, or who desire further tuition in this direction." He contends that "physiology could be as efficiently taught by other experimental methods, such as the employment of the Röntgen rays, and the use of the sphygmograph, spygmanometer (*sic*), and other modern appliances." While denying "that aseptic surgery was in any degree due to experiments on animals, without very considerable qualification," in the next paragraph he somewhat paradoxically admits that "the doctrine of cleanliness, either in lying-in or surgical wards, did not take root till Lord Lister led the way by his antiseptic technique." He reasserts his disbelief in the utility of antitoxin in diphtheria, and states that in respect to the acute infectious diseases the germ or microbial theory of disease, as well as the vaccine and serum treatment based on that theory, appear to him to be illogical. He digresses to state that his experience has satisfied him in every outbreak of small-pox, "that prompt vaccination and revaccination of contacts and others, together with other appropriate measures, were far more important aids in stamping out the disease than removal of sufferers to hospital," but adds that it is his firm belief in vaccination that compels him to question the results of these new developments in medicine—viz., vaccine and serum-therapy. Without attempting to follow Dr. Wilson through a consideration of all the particular infectious diseases dealt with in detail in the Report, it will suffice to say that he claims each of these diseases as confirming his conclusion as to the illogicality of the germ theory of disease.

In a cogent letter to the *Times* of March 13th, Lord Cromer thus sums up the net result:—

"I do not think that any impartial person will be able to read this illuminating Report without coming to the conclusion that, broadly speaking, the supporters of vivisection have proved their case." This will be the view of the medical profession.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Meeting at Long Grove Asylum.

THE quarterly meeting of this association was held on Feb. 22nd (by the courtesy of the Visiting Committee and at the invitation of Dr. C. Hubert Bond) at the London County Asylum, Long Grove, Epsom, under the presidency of Dr. WILLIAM R. DAWSON (Inspector of Lunatics in Ireland).

Dr. Bond and other members of the medical staff of the asylum conducted the party through the admission hospitals, villas, wards, administrative and medical departments of the institution, and the inspection was followed by a luncheon, at which the company included Mr. A. O. Goodrich (chairman, Asylums Committee, London County Council), Mr. A. H. Trevor (Commissioner in Lunacy), Mr. T. Hunter (chairman, Long Grove Asylum Committee), Mr. H. F. Keene (clerk of the Asylums Committee), Mr. W. Clifford Smith, M.Inst.C.E. (Asylums Engineer), Dr. F. W. Mott, (pathologist to the London Asylums), Mr. G. T. Hine, F.R.I.B.A. (architect of Long Grove), and the following past presidents of the association: Sir George Savage, Mr. H. F. Hayes Newington (treasurer of the association), Dr. P. W. Macdonald, Dr. R. Percy Smith; also Dr. Briscoe and Dr. Boycott.

Sir GEORGE SAVAGE spoke in terms of high praise concerning the equipment and administration of the asylum, and passed on to congratulate Dr. Bond on his recent appointment as one of H.M. Commissioners in Lunacy, in which new sphere he, in the name of the association, wished him every success, though with a tinge of real regret at his loss from the association and from the asylum, where he was so much esteemed.

Dr. BOND'S health having been pledged with much heartiness, he replied in a warm and grateful speech.

Mr. HAYES NEWINGTON proposed the toast of "The Visiting Committee of Long Grove Asylum," and complimented all concerned on the admirably enlightened and scientific equipment of the institution and the cordial relations subsisting between the committee and the staff.

Mr. HUNTER, in responding to the toast, said he had a great love for the work of looking after poor mentally afflicted people, and he had a splendid committee to work with. He related the history connected with the formation and equipment of the asylum, and proceeded to speak in high terms of the character and work of Dr. Bond. He was also very pleased at the cordial relations between the committee and the medical staff, and expressed their sense of loss at the departure of Dr. Bond.

Mr. GOODRICH proposed "The Medico-Psychological Association," and in doing so referred to the fact that it was established 70 years ago, and during the time which had elapsed since there had been a great deal done by it in raising the standard of the medical work in asylums as well as increasing the efficiency and status of the nurses, male and female, in asylums. He and other members of the Asylums Committee were pleased and interested to learn that certain of the universities had arranged to grant diplomas in Mental Diseases.

Dr. DAWSON, in the name of the association, replied, and expressed the thanks of members for Mr. Goodrich's remarks. In conclusion, he expressed their thanks for the hospitality with which they had been received by Dr. Bond.

Mr. TREVOR assured the gathering that Dr. Bond would receive a warm welcome from the other Commissioners in Lunacy whom he was about to join.

Papers Read.

Dr. G. F. BARHAM then read a paper entitled "Insanity with Myxœdema." He said the conception of the etiological

significance of myxœdema in reference to the mental disorder known as insanity of myxœdema had been much modified since hypothyroidism was regarded as the principal causal factor. The question to be answered was, To what extent were the symptoms of insanity occurring with myxœdema influenced during the recovery from that disease under thyroid treatment? It was uncommon to see in an asylum a case showing only the apathy and the volitional and memory defects of simple myxœdema; mostly there were insane ideas indicating a more complicated process. The mental symptoms were often examples of manic-depressive insanity or dementia præcox, or they might show dissociation or other mental processes underlying hysteria. He related a very illuminating case in a married woman, aged 34, who was the survivor of twins, and in whose family there were several instances of insanity. She was married 11 years, and in that time bore eight children. Following the third confinement she had symptoms of myxœdema, with terrifying dreams and visions. She made a fair recovery. After the four succeeding confinements there were always great prostration and debility, with severe head pains, insomnia, and loss of appetite. She also took to spirit drinking, and showed various unfounded suspicions. Physically she was in poor health, and the extremities were cold and pale, but there was no organic disease of any organ, and the reflexes were normal. The life of the patient was deeply influenced by certain incompatible emotional factors at conflict with one another. He contended that though under thyroid treatment the patient appeared to recover, so that she was able subsequently to remain outside an asylum, the abnormal mental state was an indication of the independent progress of the psychosis. He therefore concluded that the prognosis of insanity with myxœdema was not so favourable as had been frequently thought to be the case.—The subject was discussed by Dr. T. E. K. STANSFIELD, who narrated the case of a woman who married at the age of 20 and had four children. The symptoms of myxœdema were first noticed at her fourth pregnancy. Phosphorus had been given under the prescription of specialists, and a bad prognosis was given. This was in 1888, and it was decided to treat her with glycerine extract of sheep's thyroid, as suggested by Dr. George Murray, of Newcastle. The reaction was remarkably good, and she was eventually discharged recovered. Three years later she again became pregnant, and the birth was premature at the sixth month. For two years following she had mild psychasthenia, from which she recovered.—Dr. J. R. LORD said his own experience agreed with that given by Dr. Barham, and supported the prognosis he had given. In his cases there had nearly always been considerable general arterio-sclerosis, with, in some cases, alcoholism as a secondary factor. Psycho-analysis could not be entered into with every case, as it required too much time.—Dr. M. EDEN PAUL remarked that many cases of hypothyroidism, as the general practitioner was well aware of them, did not now come under the notice of the psychologist; they were treated by thyroid extract by the medical man. Those were the cases which justified the favourable opinion when so treated which was found expressed in general medical literature. The very fact that such a case came under the notice of the asylum medical officer showed that thyroid treatment had failed to remedy the condition.—Dr. BARHAM replied, stating that in the cases of the kind in that asylum he had not noticed arterio-sclerosis. There was one case now in the asylum, but her mental symptoms were much too acute to permit of any investigation.

Dr. DAVID BLAIR (Lancaster) read a paper on Forced Feeding, setting forth his experiences in keeping alive by forcible means patients, chiefly female, who uniformly resisted to their utmost every attempt at compelling feeding and the other necessary functions. In one such case the patient was kept alive for nine years, and he paid a tribute to the devotion of the nurses over such a long period.—The question was discussed by a number of members, and the comparative merits of nasal and œsophageal feeding were debated. The latter form was considered the more rapid, while the former was preferable for the most violent type of patient.

Dr. BERNARD HART read a highly interesting paper entitled "A Case of Double Personality," and, owing to the time of the meeting having expired, it was decided to adjourn the reading of the other papers which had been included in the programme.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on March 14th, Mr. RICKMAN J. GODLEE, the President, being in the chair.

The Secretary reported the death on Feb. 10th, 1912, at the age of 84, of the Right Hon. Lord Lister, O.M., F.R.S., past Member of the Council, and stated that the College was officially represented at the funeral service in Westminster Abbey on Feb. 16th by Mr. R. J. Godlee, President, and Mr. C. Mansell Moullin and Mr. Clinton T. Dent, Vice-Presidents.

Sir HENRY MORRIS, the Senior Member of Council, in moving a vote of condolence, referred to Lord Lister in the following words:—

"By the death of Lord Lister on Feb. 10th, 1912, surgery has lost her most brilliant student and her greatest master, England one of her most famous sons, the world one of its most illustrious citizens. He raised surgery from a dangerous and precarious practice to a precise, safe, and beneficent art, and in doing so his name became renowned throughout the civilised world. His methods have been adopted in every clime and country, and the benefits which flow from his discoveries are blessings conferred upon every race of mankind. His perspicacity, his natural insight, his fertility of resource, his power of close and discriminating observation, his philosophical reasoning, his inflexible pursuit of truth, his steadfastness of purpose, his capacity for taking pains, his unwearied patience, and his undaunted efforts to triumph over difficulties stamped him as a great example of true and scientific genius. The human sympathy which caused him to deplore the great mortality due to infective surgical disease, his solicitude to prevent suffering and premature death, his patient and unceasing labour to overcome them, and his gratification at the ultimate success of his efforts to ameliorate pain and prolong life eminently distinguished him as a great philanthropist. His gentle nature, his deep compassion, his courteous and dignified bearing, his imperturbable temper, his resolute will, his indifference to ridicule, his tolerance of hostile criticism combined to make him one of the noblest of men. His work will last for all time, its good results will continue throughout all ages, humanity will bless him for evermore, his fame will be immortal. In the fulness of years, after a glorious and satisfying career, crowned with great and various honours, having witnessed the successful completion of his work, the gentle hand of Death laid hold upon him, and Lister passed from among us. His funeral was a vast and striking testimony to the greatness and the usefulness of his life. His body perisheth, but the influence of his mind will continue everlastingly."

It was resolved that this memorial of esteem and admiration be printed, surrounded by the symbol of mourning, in the Council's minutes. It was further resolved that an inscribed tablet should be placed in a suitable and conspicuous position within the walls of the College, to serve as evidence to future generations of the honour, respect, and reverence in which the great founder of aseptic surgery was held by his contemporaries and immediate successors.

It was resolved that the following letter should be sent to Professor J. J. Lister:—

DEAR SIR,—I am directed by the President, Vice-Presidents, and Council of the Royal College of Surgeons of England to convey to you, and through you to the other members of the late Lord Lister's family, the sincere condolence of the Council and of the general body of Fellows and Members of this College on your bereavement.

They desire to express their belief that you cannot but be gratified and consoled by the numerous proofs which have been forthcoming of the universal and profound admiration for Lord Lister's pre-eminent services to surgery and mankind; and to assure you that this College, of which Lord Lister was so illustrious a Fellow, and on the Council of which he served for eight years, will ever hold his memory in the greatest honour and regard.

I am also directed to enclose you a copy of a memorial statement, and a resolution thereon, passed at the ordinary meeting of the Council held this day.

I remain, &c.,

(Sgd.) F. S. COWELL.

A report was read from Mr. C. H. Golding-Bird on the proceedings of the Central Midwives Board during the past year. The report was received and entered on the minutes, and the best thanks of the Council were given to Mr. Golding-Bird for his services as the representative of the College on that Board.

The PRESIDENT reported that Professor Arthur Keith had duly and properly delivered a course of six lectures on Certain Phases in the Evolution of Man.

The PRESIDENT reported that the committee on the National Insurance Act had held meetings at the College on Feb 6th and 26th, and a joint meeting with the committee of the Royal College of Physicians and representatives of the Society of Apothecaries at the Royal College of Physicians on March 5th, and that at this joint meeting the following resolution was adopted:—

That the Medical Faculties of the Universities of England and Wales be invited to send each a representative to join with the Committees appointed by the Royal Colleges of Physicians and Surgeons and Representatives of the Society of Apothecaries in endeavouring to safeguard the interests of their Graduates, Licentiates, Fellows, and Members in so far as they may be affected by the National Insurance Act.

The PRESIDENT reported that he and Sir Alfred Pearce Gould appeared before the Royal Commission on University Education in London on Feb. 23rd and gave their evidence on the subject of dental education in London.

A letter was read from Lady Butlin thanking the Council for the kind expression of their sympathy on the occasion of the death of her husband.

A letter was read from the Board of Education: (1) transmitting a copy of a note from the German Ambassador stating that the news of the death of Lord Lister had been received with keen regret in Germany, and conveying the condolences of the Imperial Chancellor and of the Prussian Government to the official departments interested and to the institutions of which Lord Lister was president; and (2) expressing the Board's own regret at the death of this great surgeon and man of science.

A letter was read from the executors of the late Lord Lister that under the terms of his will he had bequeathed his manuscripts and sketches to the Royal College of Surgeons of England.

The PRESIDENT stated that he had received several letters expressing appreciation of the attitude adopted by the Council in reference to the National Insurance Act.

An invitation from the President and Council of the Royal Society was read, asking the College to send a delegate to the celebrations on July 15th, 16th, and 17th of the 250th anniversary of the foundation of the Society. The President was appointed the delegate of the College.

An invitation was read from the Chancellor and Provost of Trinity College, Dublin, asking the College to send two delegates to the Bicentenary Festival of the Medical School of Trinity College on July 4th, 5th, and 6th. The President and the senior Vice-President, Mr. C. Mansell Moullin, were chosen as the delegates.

Sir John Tweedy was chosen as the representative of the College on the General Committee of Organisation of the International Historical Congress to be held in London in 1913.

A letter was read addressed to the President by Dr. Arthur Dean Bevan, of Chicago, reporting that the members of the American Medical Association were greatly pleased with Mr. Hallett's address on methods of conducting examinations for licences to practise medicine, and thanking the President for having sent him to their Conference.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 9071 births and 4930 deaths were registered during the week ending March 16th. The annual rate of mortality in these towns, which had steadily declined from 21·6 to 14·4 per 1000 in the five preceding weeks, slightly rose to 14·6 per 1000 in the week under notice. During the first eleven weeks of the current quarter the mean annual death-rate in these large towns averaged 16·5 per 1000, while in London during the same period the average death-rate did not exceed 15·6 per 1000. The annual death-rates last week in the several towns ranged from 6·2 in Grimsby, 7·5 in Ilford, 8·5 in Hornsey, 8·7 in Eastbourne, and 8·8 in Gillingham, to 19·3 in Liverpool, 20·3 in Manchester, 22·7 in Swansea, 23·4 in St. Helens, and 27·6 in Salford.

The 4930 deaths from all causes were 84 in excess of the number in the previous week, and included 434 which were referred to the principal epidemic diseases, against 394 and 378 in the two preceding weeks. These 434 deaths from the principal epidemic diseases included 159 from whooping-cough, 137 from measles, 56 from infantile diarrhœal diseases, 55 from diphtheria, 14 from enteric fever, and 13 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3 per 1000, against 1·2 and 1·1 in the two preceding weeks. The deaths attributed to whooping-cough, which had declined continuously from 186 to 136 in the five preceding weeks, rose to 159 last week, and caused the highest annual death-rates of 1·7 in Walsall and in Rhondda, 1·8 in Darlington, 1·9 in Coventry, in Sheffield, and in Merthyr Tydfil, and 2·3 in Edmonton. The deaths referred to measles, which had been 88, 109, and 101 in the three preceding weeks, increased to 137 last week; the highest annual death-rates from this cause were 1·8 in Nottingham, in Manchester, and in Newport (Mon.), 2·5 in York, 5·0 in Warrington, and 5·2 in Salford. The fatal cases of infantile diarrhœa, which had increased from 39 to 53 in the three previous weeks, further rose to 56 last week, and included 24 in London and its suburban districts, and 3 in Liverpool. The deaths attributed to diphtheria, which had been 44, 53, and 49 in the three preceding weeks, rose to 55 last week; 18 deaths were recorded in London and its suburban districts, 4 in Birmingham, in Liverpool, and in Leeds, and 3 in Bradford. The deaths referred to enteric fever, which had been 20 and 14 in the two preceding weeks, were again 14 last week, and included 2 in Liverpool, 2 in Barnsley, and 2 in Cardiff. The fatal cases of scarlet fever, which had increased from 17 to 25 in the three preceding weeks, declined to 13 last week, of which number 3 occurred in Liverpool, 2 in London, and 2 in Birmingham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had declined from 1512 to 1357 during the five preceding weeks, had slightly risen to 1384 on Saturday last; 152 new cases of this disease were admitted to these hospitals during the week, against 181, 160, and 161 in the three preceding weeks. These hospitals also contained on Saturday last 1089 cases of diphtheria, 519 of whooping-cough, 219 of measles, and 61 of enteric fever, but not one of small-pox. The 1106 deaths from all causes recorded in London were 46 fewer than the number in the previous week, and were equal to an annual death-rate of 12·8 per 1000. The deaths referred to diseases of the respiratory system, which had steadily declined from 545 to 259 during the five preceding weeks, further fell to 224 last week, and were 60 below the number registered in the corresponding week of last year.

Of the 4930 deaths from all causes in the 94 large towns, 174 resulted from different forms of violence, and 382 were the subject of coroners' inquests. The causes of 41, or 0·8 per cent., of the deaths registered last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and its 14 suburban districts, in Manchester, Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, Nottingham, and in 53 other smaller towns. The 41 uncertified causes of death last week included 12 in Liverpool, 6 in Birmingham, 4 in Salford, and 2 each in Bootle, in St. Helens, and in Tynemouth.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns, having an estimated population of 2,182,400 persons in the middle of this year, 1222 births and 643 deaths were registered during the week ending March 16th. The annual rate of mortality in these towns, which had been 18·7 and 17·5 per 1000 in the two preceding weeks, further fell to 15·4 per 1000 in the week under review. During the first 11 weeks of the current quarter the mean annual rate of mortality in these towns averaged 18·6 per 1000, and was 2·1 per 1000 above the mean rate recorded during the same period in the 94 large English towns. The annual death-rates in the several Scotch towns last week ranged from 8·3 in Coatbridge, 8·6 in Paisley, and 9·1 in Kirkcaldy, to 19·3 in Leith, 20·0 in Motherwell, and 27·5 in Greenock.

The 643 deaths from all causes were 88 fewer than the number in the previous week, and included 80 which were

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.
§ Poliomyelitis became notifiable in the Administrative County of London on Sept. 1st, 1911.

referred to the principal epidemic diseases, against numbers decreasing from 120 to 76 in the three preceding weeks. Of these 80 deaths, 47 resulted from measles, 8 from diphtheria, 8 from infantile diarrhœal diseases, 7 from scarlet fever, 6 from whooping-cough, and 4 from enteric fever, but not one from small-pox. These 80 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·9 per 1000. or 0·6 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had declined from 63 to 39 in the four preceding weeks, increased to 47 last week, and included 24 in Glasgow, 5 in Leith, 4 in Edinburgh, 4 in Kilmarnock, and 3 in Motherwell. The deaths referred to diphtheria, which had been 22, 9, and 8 in the three preceding weeks, were again 8 last week; 3 deaths were registered in Glasgow and 2 in Edinburgh. The fatal cases of diarrhœa among infants under two years of age, which had declined from 14 to 8 in the four preceding weeks, were again 8 last week, and comprised 3 in Glasgow, 3 in Dundee, and 2 in Aberdeen. The deaths attributed to scarlet fever, which had increased from 2 to 10 in the four preceding weeks, declined to 7 last week, 3 deaths were recorded in Greenock, 2 in Glasgow, and 2 in Aberdeen. The deaths referred to whooping-cough, which had decreased from 18 to 8 in the three preceding weeks, further fell to 6 last week. The 4 fatal cases of enteric fever were slightly in excess of the average in recent weeks.

The deaths referred to diseases of the respiratory system, which had steadily declined from 220 to 136 in the five preceding weeks, further fell to 98 last week, and 25 deaths were attributed to different forms of violence.

VITAL STATISTICS OF LONDON DURING 1911.

IN the accompanying table statistics of sickness and mortality in the City of London and in each of the metropolitan boroughs are summarised for the year 1911. With regard to the notified cases of infectious disease, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to a rate of 5·4 per 1000 of the population, estimated at 4,522,628 persons in the middle of the year; in the three preceding years the rates had been 7·4, 6·6, and 4·5 per 1000 respectively. Among the various boroughs the rates last year ranged from 3·3 in the City of Westminster, 3·5 in Kensington, 3·6 in the City of London, 3·9 in Paddington, and 4·2 in Hampstead, to 6·1 in Southwark, 6·2 in Hackney, 6·8 in Deptford, 7·2 in Woolwich, 7·6 in Finsbury, and 8·1 in Greenwich. The cases of small-pox notified during the year numbered 63, against 4, 21, and 7 in the three preceding years; of these 63 cases 39 belonged to Stepney, 11 to Poplar, 3 to Hackney, 3 to Shoreditch, and 3 to Bethnal Green. The prevalence of scarlet fever showed a slight decline, 10,489 cases being notified in 1911, against 10,509 in 1910. Among the metropolitan boroughs the greatest proportional prevalence of this disease was recorded in St. Marylebone, Hackney, Southwark, Lambeth, Wandsworth, Deptford, Greenwich, and Woolwich. The number of scarlet fever patients admitted into the Metropolitan Asylums Hospitals last year was 9631, against 20,862, 16,183, and 9889 in the three preceding years; 1878 cases remained under treatment at the end of the year, against 3498, 2329, and 1574 at the end of the three preceding years. Diphtheria showed an increased prevalence last year, 7389 cases being notified, against 5494 in the previous year; this disease was proportionally most prevalent in Fulham, St. Pancras, Finsbury, Bermondsey, Greenwich, Lewisham, and Woolwich. There were 6336 diphtheria patients admitted into the Metropolitan Asylums Hospitals last year, against 6797, 5799, and 4882 in the three preceding years; 1294 patients remained under treatment at the end of the year, against 1241, 904, and 827 at the end of the three preceding years. The prevalence of enteric fever showed a marked decline last year, only 1025 cases being notified, against 1284 in the previous year. Among the several metropolitan boroughs this disease was proportionally most prevalent in Paddington, St. Pancras, Finsbury, the City of London, Poplar, and Stepney. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals was 552, against 708, 539, and 745 in the three preceding years; 76 cases remained under treatment at the end of the year, against 147, 62, and 88 at the end of the three preceding years. The greatest proportional prevalence of erysipelas occurred in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, Deptford, and Greenwich. The 303 cases of puerperal fever notified during the year included 30 in Stepney, 24 in Wandsworth, 23 in Fulham, 21 in Lambeth, 17 in St. Pancras, 16 in Hackney, and 15 in Woolwich. Of the 101 cases of cerebro-spinal meningitis, 13 belonged to Islington, 11 to Battersea, 9 to Lambeth, 7 to St. Pancras, 7 to Hackney, and 7 to Stepney. Poliomyelitis has been notifiable in London since Sept. 1st, 1911, and from that date until the end of the year 69 cases were notified; of these, 9 belonged to Lambeth, and 5 each to Hackney, Stepney, Poplar, Wandsworth, and Camberwell.

The mortality figures in the table relate to the deaths of persons actually belonging to the several boroughs, and are obtained by distributing the deaths in institutions among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations. During last year the deaths of 67,827 persons belonging to London were registered, equal to a corrected death-rate of 15·8 per 1000, the rates in the three preceding years being 14·4, 14·6, and 13·3 per 1000. Among the several boroughs the lowest corrected death-rates last year were 10·8 in Hampstead, 11·8 in Lewisham, 12·7 in Wandsworth, 13·6 in Stoke Newington, and 13·7 in Woolwich; the highest rates were 18·3 in Bethnal Green, 18·8 in Bermondsey, 19·2 in Southwark, 19·5 in Poplar, 20·4 in Finsbury, and 21·1 in Shoreditch. The deaths from all causes included 9858 from the principal infectious diseases; of these, 9 resulted from small-pox, 2570 from measles, 172 from scarlet fever, 612 from diphtheria, 1038 from whooping-cough, 144 from enteric fever, and 5313 from diarrhœa and enteritis among children under two years of age. The death-rates from these diseases in the aggregate ranged from 0·7 in Hampstead and in the City of London, 0·8 in the City of Westminster, 1·2 in Holborn and in Woolwich, and 1·3 in Lewisham, to 3·1 in Stepney, 3·2 in Finsbury, 3·6 in Bethnal Green, 3·7 in Shoreditch, and 4·0 in Poplar. Of the 9 deaths from small-pox 7 belonged to Stepney and 2 to Poplar. The 2570 fatal cases of measles were 656 in excess of the corrected average number for the five preceding years; the greatest proportional mortality from this disease occurred in Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar. The 172 deaths from scarlet fever were 298 fewer than the corrected average number; this disease was proportionally most fatal in St. Marylebone, Islington, Stoke Newington, Holborn, Finsbury, Poplar, and Deptford. The 612 fatal cases of diphtheria were 31 below the corrected average number; the highest death-rates from this disease were recorded in Hammersmith, Hampstead, Finsbury, Shoreditch, and Poplar. The 1038 deaths from whooping-cough showed a decline of 302 from the corrected average number; this disease was proportionally most fatal in Paddington, Kensington, Stoke Newington, Bethnal Green, Southwark, Bermondsey, and Deptford. The 144 fatal cases of enteric fever were 57 below the corrected average; the greatest proportional mortality from this disease was recorded in Hammersmith, Fulham, Holborn, Finsbury, and Poplar. Diarrhœa and enteritis among children under two years of age was proportionally most fatal in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, Deptford, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last year from the principal infectious diseases, excluding diarrhœa, was 0·5 per cent. below the average.

PHARMACISTS AND COPIES OF PRESCRIPTIONS.—

At a meeting of the Western Pharmacists of London on March 13th a discussion took place on "The Giving of Copies of Prescriptions." The general conclusion was that copies should not be given except where the pharmacist was certain that it would only be used by the patient for whom it was written, and that even for this the medical man's consent should, if possible, be obtained. In no circumstances should a copy be given in order to be passed from one person to another. Several medical men who took part in the discussion agreed that they would have printed upon their prescription forms that no copies be given. In cases where it was necessary to give a copy the meeting decided that no charge should be made for it by the pharmacist.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeon: A. McCloy, to the *Victory*, additional, for disposal, and to the *Research*, for surveying season.

ARMY MEDICAL SERVICE.

Surgeon-General John C. Dorman, C.M.G., is placed on retired pay (dated March 20th, 1912).

Colonel Michael W. Kerin, C.B., to be Surgeon-General, vice J. C. Dorman, C.M.G., retired (dated March 20th, 1912).

The undermentioned Lieutenant-Colonels from the Royal Army Medical Corps to be Colonels:—Charles E. Nichol, D.S.O., vice F. J. Lambkin, deceased (dated March 9th, 1912). Sinclair Westcott, C.M.G., vice M. W. Kerin, C.B. (dated March 20th, 1912).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majors to be Lieutenant-Colonels:—Samuel G. Moores, vice C. E. Nichol, D.S.O. (dated March 9th, 1912); Thomas B. Beach, vice R. J. Copeland, placed on half pay (dated March 10th, 1912); Coryndon W. R. Healey, vice S. Westcott, C.M.G. (dated March 20th, 1912).

Lieutenant-Colonel Robert J. Copeland is placed temporarily on the half-pay list on account of ill-health (dated March 10th, 1912).

Major Walter B. Fry, from the seconded list, is restored to the establishment (dated Feb. 21st, 1912).

Lieutenant-Colonel W. L. Gray has arrived in India for a tour of foreign service. Lieutenant-Colonel H. S. McGill has been appointed Senior Medical Officer on board the transport s.s. *Plassy*, which left Bombay for Southampton on March 13th. Lieutenant-Colonel J. B. Wilson has embarked for a tour of service in Jamaica. Lieutenant-Colonel F. P. Nichols has assumed medical charge at Bodmin.

Major J. Hennessy, on completion of service in India, has been appointed to the Southern Command for duty. Major P. S. O'Reilly has been transferred from the Convalescent Depôt at Wellington to the Military Hospital at Secunderabad. Major H. S. Roch has taken up duty in South Africa. Major W. A. Woodside has joined the Station Hospital at Agra for duty. Major K. B. Barnett has been transferred from Shorncliffe to Brighton. Major P. H. Falkner has arrived home for duty from Bermuda. An exchange on the roster for service abroad has been sanctioned between Major F. W. Begbie and Major E. T. F. Birrell. Major L. Way has embarked for a tour of service in India. Major L. Humphry has been granted six months' general leave of absence home from India.

Captain R. E. Humfrey and Captain W. Benson have been appointed to the Dublin District for duty. Captain E. V. Aylen has been granted eight months' general leave of absence home from India. Captain W. C. Nimmo, from the Station Hospital at Meerut, has been appointed to the Eastern Command for duty. Captain H. B. Stack has embarked for a tour of service on the West Coast of Africa. Captain C. E. Fleming, on arrival in South Africa, has been appointed a Specialist in Ophthalmology. Captain J. J. O'Keefe has been granted eight months' leave of absence home from India. Captain E. T. Potts has been appointed to the Irish Command for duty in the Dublin District. Captain P. J. Marett has been transferred from Malta to the home establishment, for duty in the Eastern Command. Captain J. F. Grant has left Allahabad for a tour of duty in Burma. Captain A. Shepherd has joined the Station Hospital at Agra. Captain W. H. S. Burney has taken up duty at Dublin. Captain G. G. Tabuteau and Captain G. W. W. Ware have been detailed for duty on board the transport s.s. *Dongola*, which left Bombay for Southampton on Feb. 23rd. Captain P. S. Lelean has been granted five months, 26 days' general leave of absence home from India. Captain J. F. Whelan has been appointed a Specialist in the Prevention of Disease and placed in charge of the Bacteriological Research Laboratory at Jhansi. Captain R. F. M. Fawcett has embarked for a tour of service in India. Captain J. D. Richmond has taken up duty at the Military Hospital, Glasgow. Captain F. C. Sampson has been ordered to join the Scottish Command. Captain D. B. McGregor has been selected for appointment as Specialist in Electrical Science and Radiography to the Seventh (Meerut) Division. Captain T. J. Potter has joined for duty in Egypt. Captain D. T. McCarthy has been directed to proceed to Burma for a tour of service at Shwebo.

Lieutenant H. S. Blackmore and Lieutenant M. Drummond have been appointed for duty in the London District. Lieutenant R. C. Priest has been placed in Medical Charge of the Duke of Cornwall's Own Middlesex Regiment at Jalpaiguri Camp, Bengal, proceeding by route march to Lebong. Lieutenant H. V. Stanley has been placed under orders for a tour of service at Gibraltar. Lieutenant G. P. Taylor has embarked for South Africa. Lieutenant F. W. M. Cunningham has joined for duty in India. Lieutenant T. H. Dickson has been transferred from Dublin to the Military Hospital at the Curragh. Lieutenant W. T. Graham has been placed under orders to join at Oxford for duty. Lieutenant J. A. Manifold has left Glasgow for a tour of duty at Bermuda. Lieutenant J. Startin has been transferred from Kirkee to the Military Hospital at Poona.

Royal Hospital, Chelsea.—Major Herbert E. Winter, Royal Army Medical Corps, to be Deputy Surgeon, *vice* Major F. Kiddle, who has resigned that appointment (dated March 1st, 1912.

INDIAN MEDICAL SERVICE.

The King has approved of the retirement of the undermentioned officers of the Indian Medical Service: Lieutenant-Colonel Ernest Wickham Hore (dated Dec. 7th, 1911). Lieutenant-Colonel Henry Thomson (dated Feb. 1st, 1912). Lieutenant-Colonel Frank Cecil Clarkson (dated March 1st, 1912). Captain Arthur Falconer Hayden (dated Jan. 23rd, 1912).

Lieutenant-Colonel A. Coleman has taken up duty as Superintendent of the District Jail at Rawalpindi, relieving Captain C. A. Gill. Lieutenant-Colonel C. E. L. Gilbert has been granted six months' extension of leave of absence from India on the recommendation of a medical board. Lieutenant-Colonel D. T. Lane has taken up duty as Superintendent of the District Jail at Sialkot.

Major A. A. Gibbs has been appointed Medical Storekeeper to the Government of India in succession to Lieutenant-Colonel P. W. O'Gorman. Major R. H. Price has arrived home on leave of absence from India. Major H. Boulton has been appointed a Specialist in the Prevention of Disease and placed in charge of the Bacteriological Research Laboratory at Nowshera. Major H. A. Smith, civil surgeon at Agra, has been granted nine months' leave of absence home from India. The services of Major H. D. Peile have been placed at the disposal of the Commander-in-Chief.

Captain R. T. Wells, plague medical officer at Rohtak, has been transferred to Jullundur. Captain W. W. Jeudwine has been granted two years' leave of absence home from India. Captain J. G. G. Swan has been appointed Civil Surgeon at Ludhiana, relieving Captain M. Corry, who has been transferred to Multan. Captain A. W. M. Harvey has been appointed a Specialist in the Prevention of Disease and placed in charge of the Bacteriological Research Laboratory at Dehra Dun. Captain E. T. Harris has been placed under orders for duty in Burma. The services of Captain T. M. Macrae have been placed permanently at the disposal of the Government of the United Provinces of Agra and Oudh. Captain J. E. Clements has been appointed Superintendent of the Central Jail at Montgomery. Captain H. Watts has taken up duty at Lahore as Plague Medical Officer. On transfer from Jullundur, Captain H. C. Keates has been appointed to officiate as Civil Surgeon at Dera Ghazi Khan. Captain F. C. Rogers has been granted 1 year and 14 days combined furlough. Captain C. C. C. Shaw has been appointed to officiate as Civil Surgeon in the Raipur District.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

William Archibald Miller to be Lieutenant (on probation) (dated Feb. 19th, 1912).

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st North Midland Field Ambulance, Royal Army Medical Corps: Lieutenant Thomas A. Barron to be Captain (dated Jan. 10th, 1912).

3rd East Lancashire Field Ambulance, Royal Army

Medical Corps: Kingsmill Williams Jones to be Lieutenant (dated Feb. 11th, 1912).

2nd Home Counties Field Ambulance, Royal Army Medical Corps: Lieutenant Herbert S. Hollis resigns his commission (dated March 20th, 1912).

2nd West Lancashire Field Ambulance, Royal Army Corps: Transport Officer and Honorary Lieutenant Alan H. Noble resigns his commission (dated March 16th, 1912).

3rd London Field Ambulance, Royal Army Medical Corps: Lieutenant David J. Graham to be Captain (dated Jan. 3rd, 1912).

5th Southern General Hospital, Royal Army Medical Corps: Maurice Dale Wood to be Captain (dated Jan. 4th, 1912).

2nd London (City of London) General Hospital, Royal Army Medical Corps: Lieutenant-Colonel and Honorary Surgeon-Colonel Clement Godson resigns his commission and is granted permission to retain his rank and to wear the prescribed uniform (dated March 13th, 1912).

1st West Riding Field Ambulance, Royal Army Medical Corps: Lieutenant Francis Darlow to be Captain (dated Jan. 24th, 1912).

Attached to Units other than Medical Units.—Captain Thomas Brushfield resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated March 16th, 1912). Captain James K. Patrick resigns his commission (dated March 20th, 1912). Lieutenant William T. Storrs resigns his commission (dated March 16th, 1912). Lieutenant James A. Raeburn resigns his commission (dated March 16th, 1912). Major Thomas E. Stuart resigns his commission (dated March 6th, 1912).

For Attachment to Units other than Medical Units.—Gerald Lantsbery Bunting to be Lieutenant (dated March 6th, 1912). Lieutenant Richard Christopher Clarke, from the Territorial Force Reserve, to be Lieutenant (dated Jan. 28th, 1912). William Frothingham Roach to be Lieutenant (dated Dec. 1st, 1911). Lieutenant Haldinstein David Davis, from the 2nd London (City of London) Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Feb. 12th, 1912).

VOLUNTEER FORCE.

Uppingham School Cadet Corps: Acting Surgeon Harry L. Smith resigns his commission (dated March 13th, 1912).

THE TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned Officers of the Territorial Force, who have been duly recommended for the same under the terms of the Royal Warrant dated August 17th, 1908:—

Infantry.

5th Battalion, The Prince of Wales's Own (West Yorkshire Regiment): Surgeon-Captain Ernest Solly, Retired List.

Royal Army Medical Corps.

Major William Lloyd Edwards (deceased). Major David Durran, attached to the 5th (The Sutherland and Caithness Highland) Battalion, Seaforth Highlanders (Ross-shire Buffs, The Duke of Albany's).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the March issue of this journal the first place is given to an appreciative sketch of the life of a Royalist army surgeon by Major H. A. L. Howell. Richard Wiseman, the subject of the memoir, was serjeant-surgeon to Charles II. and a "great practical surgeon of his day," who "in a drunken age was a water-drinker, and at a time when licentiousness was rampant, we have every reason to believe, led a moral life." He was a good Latin scholar, and wrote several books, his treatises dealing with tumours, ulcers, diseases of the anus, king's evil, wounds, gunshot wounds, fractures and luxations, and lues venerea. In connexion with this last-mentioned disease it is interesting to note that a grateful patient settled an annuity upon Wiseman equal to £120 a year in modern money. Incidentally the memoir contains a story illustrating the power of the imagination. Wiseman had used a red ribbon as a tourniquet previous to cutting off the hand of a soldier. After the surgeon had left the patient he was hurriedly recalled because the patient was in great pain owing to the pressure, as he thought, of the red ribbon. "I was at first surprised to think I should leave the Ligature upon his Arm," said Wiseman, "that being a sure way to bring a Mortification upon the Part." After being shown the ribbon which was now in the operator's pocket, the patient "laught and was from that time in ease." A reproduction of the portrait of Wiseman in oils which is in the Royal College of Surgeons, London, forms a frontispiece to the article. Major G. E. F. Stammers and Captain G. I. Davys, I.M.S., deal with the subject of Apyrexial Malaria Carriers, and Major E. W. W. Cochrane contributes a paper on A Small Epidemic of Typhoid Fever in Connexion with Specifically Infected Flies. A short article on the Effect of Physical Training on the Pulse-rate, by Captain J. A. Black, will be read with attention, as will also the first part of Practical Hints on Marching and Health on Active Service, intended for the instruction of young soldiers, written by an ex-soldier, G. Fahey, late 88th Connaught Rangers. This paper is based on an experience of 19 years in the ranks.

THE MILITARY SURGEON.

The first 35 pages of the February number are devoted to a detailed and appreciative account of the magnificent International Exhibition of Hygiene at Dresden, by Medical Director (Surgeon-General) H. G. Beyer, U.S. Navy, United States delegate to the exposition. A special word of praise is given to the completeness of the exhibit in the British Section, of whose success it is said, "the British people may well feel proud." The untiring energy of the secretary, Mr. H. W. Armit, and his daily demonstrations are warmly praised. An exhaustive paper, a Study of the Foot and Footwear, by Captain F. W. Weed, Medical Corps, U.S. Army, discusses the evolution of the foot as seen, first in the Simiadæ, then in less civilised, and in the more civilised races of men. It traces the development of sandals, shoes, and boots to the present day, details the principles and practice of fitting boots to feet, and insists on the damage done by stockings that are too tight. This paper should be read by all young medical officers. The American army finds that salvarsan alone is sufficient for the treatment of primary and tertiary lesions, but mercury must also be used in secondary cases to assist in the final cure.

CHANGE OF DESIGNATION IN THE ADMINISTRATIVE RANKS OF THE ROYAL ARMY MEDICAL CORPS.

It is announced that the titles of Principal Medical Officer, Administrative Medical Officer, and Staff Officer to the Principal Medical Officer of a Command are about to be discontinued. In future these officers are to be called "Deputy Director of Medical Services," "Assistant Director of Medical Services," and "Deputy Assistant Director of Medical Services" respectively. This change in nomenclature brings the medical services of the army into line with those of supplies and transport and other departments.

A DRAWING-ROOM meeting on behalf of the Ragged School Union and its work among poor and crippled children will be held on Tuesday next, March 26th, at 3.30 P.M., at 10, Queen Anne-street, Cavendish-square, W., with the permission of Sir Alfred and Lady Pearce Gould. The Rev. Prebendary Webb-Peploe will preside.

UNIVERSITY OF LIVERPOOL.—The Council has decided, on the recommendation of the Medical Faculty, to found a chair of bacteriology at the University. Negotiations have been in progress for some time in regard to the bacteriological work of the city previously carried on by the late Sir Rubert Boyce, professor of pathology at the University. The new professor will hold the dual post of professor of bacteriology and city bacteriologist. The University will place at his disposal, in his capacity of city bacteriologist, accommodation at the University. The appointments to the two posts will depend upon each other, the resignation of one leading to the resignation of the other. The subject of bacteriology has so advanced in importance of late years that it has become a necessity for the University to secure the services of a trained bacteriologist. The present arrangement will be an advantage both to the city and to the University, and the completion of the negotiations is a further evidence of the readiness with which the councils of the two bodies work together to their mutual advantage. The two chairs—the vacant one of pathology and the new chair of bacteriology—will be filled up without further delay, and next session it is hoped the newly-appointed professors will enter upon their respective duties.

Correspondence.

"Audi alteram partem."

MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,—With your kind permission I should like to draw the attention of the readers of THE LANCET to certain improvements which are being effected in connexion with the Museum of the Royal College of Surgeons of England. The following letter, which is self-explanatory, is being issued by the President of the College to ophthalmic surgeons throughout the country. It is possible, however, that medical men who are not specially in ophthalmic practice may be able to help with the object mentioned in the letter.

Royal College of Surgeons of England, Lincoln's Inn-fields, London, W.C., 25th March, 1912.

DEAR SIR,—The Council of the Royal College of Surgeons of England have lately resolved to revise completely that part of the Museum which illustrates Injuries and Diseases of the Eye, and has entrusted the revision to Mr. Stephen Mayou, F.R.C.S.

The methods of preservation and mounting of specimens have improved so much since the present collection of eye preparations was made by Mr. Charles Bader in 1860–1862 that it will be necessary to replace the majority of existing specimens.

As President of the College may I ask you to assist the Council by presenting to the Museum such specimens as may help to give a complete representation of the Pathology of the Eye and of the various structures accessory to the function of vision?

Preparations should be forwarded to the Conservator of the Museum, who will acknowledge their receipt and report on them if desired.

I am, Dear Sir, Yours faithfully,
(Signed) R. J. GODLEE, President.

The Council of the College has also resolved to establish a Medico-legal Collection in connexion with the Museum, there being at the present time no standard collection in England. The scheme of classification which is to be adopted for this collection is that elaborated by Sir Henry Littlejohn and Professor Harvey Littlejohn in connexion with the Museum attached to the Department of Forensic Medicine in the University of Edinburgh. The scheme of classification is as follows:—

I. Specimens illustrating sudden or unexpected death from natural causes—e.g., conditions of the heart, brain, stomach and intestines, larynx, &c. (latent disease).
II. Deaths from mechanical violence: (*a*) Rupture of organs; (*b*) wounds—contusions, incised (cut-throat), stabs, lacerated, wounds of genital organs; (*c*) injuries and results of violence to brain; (*d*) fractures—skull, long bones, &c.
III. Death from asphyxia: (*a*) Drowning, (*b*) hanging, (*c*) strangulation, (*d*) choking, (*e*) overlaying—enlarged thymus gland.
IV. Specimens illustrating identity and post-mortem condition—e.g.: Tattoo-marks, malformations, finger-prints, foot-prints, post-mortem digestion of stomach, post-mortem discolourations and changes, post-mortem injuries, adiposis, mummification, &c.
V. Specimens illustrating: pregnancy; delivery—injuries, &c.; abortion; rape, virginity, &c.
VI. Death from burns.
VII. Death from firearms.
VIII. Infanticide.
IX. Effects of poisons.
X. Specimens of all chief poisons.
XI. Weapons of various kinds. Photographs. Microscope slides of various kinds in relation to all the above.

There are already in various parts of the Museum specimens which illustrate some of the sections included in the above list, but as regards the majority of these the College must depend on the public spirit and generosity of medical men. This letter is written in the hope that your readers may be induced to help in building up this most needful collection.

The Conservator of the Museum will gladly answer inquiries regarding the projected Medico-legal Collection and acknowledge the receipt of specimens.

There is another department of the Museum which is altogether dependent on medical men—viz., that which illustrates the development and growth of the human embryo and fœtus. In recent years the methods of preservation of such specimens have become so much more satisfactory that it will be necessary to replace some of the present specimens and to add many others.

The Conservator will gladly acknowledge the receipt of such specimens and give a descriptive account of them if the donor should so wish. It is of the utmost importance that the full history relating to the age of such specimen should be known.

You will render the Museum of the College a service if you will be so good as to bring these matters before your readers. I am, Sir, yours faithfully,

ARTHUR KEITH,
Conservator of the Museum of the Royal College of Surgeons of England.

March 20th, 1912.

THE CAUSATION OF TOXIC SYMPTOMS FOLLOWING THE ADMINISTRATION OF SALVARSAN.

To the Editor of THE LANCET.

SIR,—Although questions of priority have little interest to anyone except those immediately concerned, we hope that you will find space for the following remarks.

In a letter printed in your last issue we think Mr. Bayly does us a slight injustice in stating that our work confirms that of Major Gibbard, Major Harrison, and Lieutenant Cane. Major Gibbard and Major Harrison and their collaborators will of course recognise that we do not wish to minimise the value of the investigations which they have conducted from the beginning of the salvarsan era in England if we call attention to the fact that our original publication was headed "Eingegangen bei der Redaktion am 20. September, 1911."

Again, we take some exception to Mr. Hort and Dr. Penfold's statement that we "resuscitated Wechselmann's theory." We have always given Dr. Wechselmann the fullest credit for having been the first to call attention to this subject, but we cannot help pointing out that we have borrowed nothing from his writings except the reference to the work of Bingel on "salt fever." Dr. Wechselmann's first paper containing this reference was published in April and his conclusions regarding the toxicity of saline were incorrect. We immediately confirmed and corrected Bingel's work on man on a more extensive scale and had already demonstrated the method of eliminating the toxicity of distilled water before the publication of Dr. Wechselmann's second paper in July. Indeed, we were able to include some account of this work in our book on syphilis which was in the hands of the booksellers in October. This note was written before the publication of Dr. Wechselmann's second paper.

Further, we should like to point out that Dr. Wechselmann and others have only demonstrated clinically that salvarsan dissolved in freshly distilled water is non-toxic to man. They *inferred* that the toxicity was due to some bacterial product in the water. We, however, believe that we alone have traced the cause of these phenomena experimentally, producing direct, as opposed to indirect, evidence, and that we alone demonstrated clearly the difference in the reaction to salvarsan of acute and chronic syphilitics, thus clearing up several points which had been held as objections to what we will call "Wechselmann's theory."

Mr. Hort and Dr. Penfold will take exception to some of the phrases we have used above. The origin of their letter appears to be the reference we made to their work in our paper in THE LANCET. We must apologise for the seeming discourtesy of a footnote, but we much regret that our paper was in the press before the meeting of the Pathological Society took place. Nothing in our paper should be taken as a reply to anything Mr. Hort and Dr. Penfold may have published. We readily confess that we do not fully understand the intricacies of their work, and therefore we cannot enter into any profitable discussion of it. A help to our understanding will be the publication of the experiments which they have made in support of their views. A cursory description before a medical society cannot be accepted as "publication" of experiments. Few can follow the argument, and the author cannot be held to any one statement. Of still less value is the account of these meetings in the papers. In the report of Mr. Hort and Dr. Penfold's paper published in THE LANCET, no detail was given, and the Proceedings of the Pathological Society are not yet published; where, therefore, can we find verification of their present statement: "He (Dr. McIntosh) confessed that he had not carried out the control experiments we had shown to be essential"? We strongly protest against such confessions being put into our mouths. Mr. Hort and Dr.

Penfold have put a construction upon the conversation which was certainly not intended.

The expressions "proved to demonstration" and "indisputable fact" which appear in their letter in reference to their work leave us cold. They indeed imply a great confidence, a confidence which we hesitate to place in our own researches; nevertheless, we had thought that we had "proved" the opposite, and, so far as is possible at present, we must dispute their "indisputable fact." We repeat that we "await the publication of precise technical details" or an indication of the site if they have already been published.

We are, Sir, yours faithfully,

J. MCINTOSH,
P. FILDES,
H. DEARDEN.

London Hospital, E., March 19th, 1912.

THE INTESTINAL FLORA.

To the Editor of THE LANCET.

SIR,—Dr. Edwin Goodall, in your issue of March 9th, calls attention to the *résumé* of my researches in my article of Feb. 24th.

I think that judgment should be withheld until all the facts are known. My article *in extenso* will appear soon in the *Centralblatt für Bakteriologie*, 1 Abt. Orig. Bd. 62, and I shall then be glad of any just and impartial criticism. I may point out here, however, that Dr. Goodall is at fault in expressing astonishment that indol and its congeners are produced in the colon. It is surely a fact, which anyone who has seen a preparation of fæces has noticed, that the intestinal flora of an adult man is to a large extent composed of microbes which are known to form these substances *in vitro*. That these same substances are produced *in vivo* is obvious, for in the colon there are decomposition products of the tryptic digestion and absence of sugar. There are, moreover, other facts which cannot have escaped so careful an observer as Dr. Goodall. 1. It is a recognised fact, to be found in every text-book of physiology, that in fistula of the ileum the discharge has never been observed to give the reactions of indol, although as much as 1000 grammes have been used in the investigation. 2. In the process of tryptic digestion, carried out under aseptic conditions, E. Fischer and Aberdhalden were never able to detect these substances. When, on the other hand, the digestive process was accompanied by bacterial growth indol and its allies were produced. 3. As Dr. Goodall knows, the stools of the infant at the breast never give the indol reaction. The reason of this is that the intestinal flora of these infants includes none, or only a negligible number, of the indol-producing organisms. 4. In a series of observations on the bat, carried out in collaboration with Professor Metchnikoff, Berthélot, and others (*Annales de L'Institut Pasteur*, 1909), it was shown that in this animal, which has an extremely short colon, the distillate from the stools contained neither indol nor its allies. 5. It is also a matter of general knowledge that when one changes the intestinal flora for the better, the sulpho-conjugates sensibly diminish and in some cases almost disappear, as I can demonstrate on myself.

These facts leave no doubt that indol and its allies are formed by the microbes of the large intestine. Now there is still in question whether the liver suffers from this condition of intestinal intoxication. In this connexion the amount of sulpho-conjugates in the urine affords valuable testimony. In the breast-fed infant there is no evidence of the formation of these substances, but as soon as feeding by cow's milk is commenced intestinal putrefaction begins and sulpho-conjugates appear. Further, in the normal adult their proportion increases, and in constipated subjects becomes augmented even to four times the normal amount (*vide* Combie: "Sur l'Auto-Intoxication Intestinale"). It is a known physiological fact that the sulpho-conjugates are formed in the liver, and it follows that the excessive production of indol and its allies in the intestine and their absorption by the portal system must increase considerably the work of this organ, which is responsible for their elimination.

Dr. Goodall is further astonished that this flora is harmful. On this assertion, which is a consequence of the facts that I have established, I do not propose to waste words. This flora is dangerous, for it is admitted that an excess of indol in the intestine is associated with the symptoms of trouble of intestinal origin. That microbes undergo autolysis in the colon of constipated individuals there can be no doubt. In the cases operated on by Mr. Lane it was found after the operation that certain microbes had appeared in the stools which previously were absent, and it is entirely within reason to conclude that these microbes were part of the flora of the colon originally.

Dr. Goodall reproaches me for my hypothesis of the rôle of these substances of microbic origin—viz., that they act on the nerve-plexuses of the intestinal mucosa. However, the part played by the nervous system in the intestinal activities is well established by Cannon, whose excellent monograph, published a short time ago, Dr. Goodall probably knows. Perhaps I may be permitted to submit to him this question: If these substances, which I have never spoken of as toxin, are not directly or indirectly harmful, how does he explain many of the phenomena to be observed in connexion with the colon? I admit, however, that this hypothesis will have to be elaborated. My own work on chronic intoxication by intestinal bacteria is only the beginning. *Ars longa, vita brevis.*

I am, Sir, yours faithfully,

Russell-square, London, W.C., March 16th, 1912. A. DISTASO.

THE VALUE OF PNEUMOCOCCUS VACCINE IN THE TREATMENT OF PNEUMONIA.

To the Editor of THE LANCET.

SIR,—The kindly and courteous criticism of my paper in THE LANCET by such a distinguished authority as Sir R. Douglas Powell demands on my part an immediate reply.

The first question is a most important one, and relates to the superiority or otherwise of an autogenous vaccine as opposed to a homologous or stock vaccine. On strictly scientific grounds a vaccine ought to be autogenous, and especially in the case of the pneumococcus, which is not by any means a constant organism either as regards strain or virulence, but the difficulty in preparing an autogenous vaccine in a case of acute pneumonia is very great, and could only be done by puncturing the lung, as Sir Douglas Powell points out, at great hazard. We are therefore compelled to use a stock vaccine, the dose of which need not be so carefully regulated as in the case of autogenous vaccines, and which in my hands has proved most satisfactory. With regard to the stage of the disease at which it ought to be injected my experience of a large number of cases of pneumonia teaches me that the earlier it is given the better, and it is now my practice to give a good dose immediately the disease is recognised. Of course, in many cases of pneumonia which are running a favourable course vaccine is not necessary, and I thoroughly agree with Sir Douglas Powell as to its value in those cases where a prolonged pyrexia occurs without pus formation.

The criticism of my mortality table is quite warranted, and I quite admit that a death-rate of 16 per cent., based on 207 cases of pneumonia treated with vaccines, is not any great advance on the results obtained by other methods of treatment. I would, however, like to express my belief that in the future, with further experience and knowledge of vaccine, this death-rate will be still further reduced.

With regard to the dosage, I take it the object of giving vaccine is to produce an immunity in the blood against the pneumococci and stimulate the formation of anti-pneumotoxin. The doses which we have been accustomed to give are in my opinion too small, and any immunity which is produced is of too short a duration and of a temporary character. For this reason, and bearing in mind that we have never observed any reaction or ill effects from its use, we have been encouraged to largely increase the dose from 50 to 100, or even 150, millions in a serious case.

I cannot see any reason why acute pneumonia should necessarily run a course of six, seven, or eight days, and we have recently treated two acute cases in hospital with continuous injections of vaccine (50 millions every four hours) with the happy result of aborting the attack, bringing the temperature to normal, and relieving the patients of the distress due to respiratory embarrassment and toxic absorption. The physical signs of consolidation were not much influenced by the treatment, but there was a complete absence of toxæmia. These cases will shortly be published, and I feel sure that the treatment of pneumonia will in the future be directed to

aborting or cutting short an attack rather than in guiding the disease for a stereotyped number of days to a crisis, by which time the patient is often poisoned by toxæmia and his heart paralysed by exhaustion. By the administration of anti-toxin we abort an attack of diphtheria, and in my judgment we must use every endeavour to stop an attack of acute pneumonia. I take it that the "crisis" in pneumonia is the exact time when a sufficient amount of anti-pneumotoxin has been formed in the blood automatically, to counteract the toxins of pneumococci.

If we can bring about that result early in the disease by the use of vaccines or serum we will save an enormous amount of suffering and greatly reduce the mortality from the disease which is so aptly described by Osler as "the Captain of the Men of Death."

I am, Sir, yours faithfully,

Liverpool, March 18th, 1912. NATHAN RAW.

A NEW GALACTAGOGUE.

To the Editor of THE LANCET.

SIR,—It is well known that the food of an animal and the season of the year modify the quantity and the quality of the milk secretion. Goats' milk, for instance, is said to be astringent after the animals have eaten the leaves of the oak or pine trees, and to act as a gastric sedative if the wild hellebore is made a part of the diet.

It was customary in the old days to prescribe the diet, not only for the infant or invalid, but for the animal from whose milk the patient was to be fed. An instance occurred in the practice of the famous Italian physician of Milan, Jerome Cardan, when about the end of the sixteenth century he was called to Scotland to attend Mary Queen of Scots. The Archbishop of St. Andrews, John Hamilton, whose brother was heir to the throne of Scotland, never had robust health, and was at that time suffering from some lung disease, probably phthisis. Advantage was taken of Cardan's presence in Edinburgh to ask him to attend on and prescribe for the archbishop. He treated him with beef-juices made of blood serum; chicken broths flavoured with cinnamon, wine and ginger; but milk was the "sheet anchor" in the dietary. The savant contended that milk kept the stomach open and cleared the brain, and he ordered the archbishop to drink from two to four pints of ass's milk, either all at once or in several doses with no greater interval than an hour. The ass was treated also. The animal was ordered to be provided with mild herbs, such as mallow, juicy beetroots, rose blossoms, as well as fresh corn and barley, and the mother and foal were ordered to run together freely in a meadow daily. This prescription gives a hint to those interested in milk feeding of consumptives to-day.

The turnips given to a stall-fed cow impart a flavour to its milk and to the cream and butter; a similar thing occurs when the animal is fed with new clover. Leeks, onions, garlic, and other members of this group taint the milk, their active principles being secreted by the milk gland, as in the cases of oils of dill and aniseed. Before the days of artificial foods physicians were careful to order milk derived from one cow, the animal being specially fed, and in some parts of the country this is not now departed from.

Beans, peas, and lentils have long been held in esteem for increasing the milk-supply. Hippocrates recommended cabbage; Paul of Aegina the carrot, beet-root, cresses, and chicory, for this purpose. Professor Tarnier's favourite galactagogue was malt, and farmers still use the draff of the brew-house for cow feeding. Dr. Carron de la Carrière, of Paris, speaks highly of the old-fashioned goat's-rue, or as others call it, galega, formerly much used in medicine as a diaphoretic and stimulant. He has observed, when this is given to the suckling mother, the infant increases in weight and rests and sleeps better.

Our Pharmacopœia has little to offer the medical practitioner or midwifery nurse in the way of milk-inducing agents. Recently, a preparation of the cotton seed has been tried with much success, increasing the mother's milk both in quantity and in fat and casein. The product has been minutely described by Dr. Ballerin, of Paris. Cotton seeds are reduced to a fine powder, the oil and resinous matters are extracted by ether and benzine, and the active principle obtained by infusing the residue, and thereby getting rid of the colour and the odour. The resultant liquid is concentrated *in vacuo* and the blocks pulverised. This powder is free from cellulose, oil, and other indigestible products. It has no toxic properties. The active principle, so far as milk-producing properties is concerned, is edestine. The product has been administered to domestic animals, with the result that the quantity of milk increased by 30 per cent., and the fats and solids in corresponding proportion. The same results have followed its administration to lying-in or suckling mothers. Several cases of this nature have come under my personal observation. For example, a lady with her second child noticed at the fifth month that the breasts were becoming soft, and the milk diminishing in quantity. This cotton-seed powder produced a large accession of milk, and by continuing its use she was able to go on nursing without further trouble. The following is rather a severe test. A mother who had never been able to suckle more than four months has been able to continue for nine months, the baby being plump and thriving, to the great delight of the mother. The milk-supply has been abundant throughout.

Bearing in mind that artificial feeding is the most potent cause of the maladies of early infancy, and the chief factor in the production of infantile mortality, the importance of a reliable galactagogue can scarcely be over-estimated.

I am, Sir, yours faithfully,

Goswell-road, E.C., March 9th, 1912. W. LAUZUN-BROWN.

FUNGI FOUND IN TROPICAL BRONCHOMYCOSIS.

To the Editor of THE LANCET.

SIR,—In my letter on this subject I pointed out an error that Dr. A. C. E. Castellani had made in describing endomyces albicans as liquefying gelatin. The only organism of that name is E. albicans (Vuillemin) described in 1898 (*Comptes Rendus de l'Académie des Sciences*), and again by Goedelst and Vuillemin ("Les Champignons Parasites," 1902, p. 38), when they distinctly state: "La gelatine n'est jamais liquefiée." Dr. Castellani remarks that anyhow there are a number of organisms concerned in thrush, and that some of them liquefy gelatin. That seems beside the point, while he neglects the species described by M. Vuillemin, a distinguished French mycologist of world-wide reputation.

In apology for my venturing to express an opinion at all, I may point out that in his original communication Dr. Castellani (1) admits he has no evidence that his saccharomyces is a saccharomyces; and (2) offers no evidence that his endomyces are endomyces. (3) Finally it appears probable there are still two slips in the fermentation table—for instance, one organism ferments (A.G.) raffinose, but no disaccharid, and another ferments raffinose and saccharose, but not levulose. These are abnormal and in need of confirmation.—I am, Sir, yours faithfully,

Acton, W., March 18th, 1912. ROBERT CRAIK, M.D. Glasg.

THE BED ISOLATION OF CASES OF INFECTIOUS DISEASE.

To the Editor of THE LANCET.

SIR,—In the course of such unfavourable comments as have hitherto been made on the plan of "bed isolation" in dealing with infectious diseases—which, by-the-bye, have, so far as I know, only issued from those who have not given it a trial—the responsibility for its origin has been pretty definitely allotted to myself. I shall be glad therefore if you will be good enough to allow me to make some reference to the encouraging results reported by Dr. C. Rundle and Dr. A. H. G. Burton, in their excellent paper in THE LANCET of March 16th. There is just one point with which the authors are doubtless quite familiar, but which is not perhaps emphasised sufficiently by them to arrest the attention of those who have not read the original papers on the subject. I mean the paramount necessity of the routine cleansing (with a view to minimise possible aerial dissemination, as well as to effect other ends) of the mouth and throat, if not the nose, in all cases. At Mortlake every patient used on admission to be given a separate spray producer and a new tooth-brush. The tooth-brush was used at least twice a day, and the atomiser, with an oily disinfectant, every four hours at first.

Of course (in the case of small hospitals especially) there are many contingent advantages in the adoption of the method of bed-isolation, but, as I have tried to point out, in a recently published volume of essays, it is a method that

depends on principles that should be always applied in dealing with cases of infectious disease, whether kept at home or sent to hospital. The use of symbolic barriers, like the red cord, or material barriers, like the glass partition, has in private practice an analogue in the fetish of the wet sheet. In all these cases attention is directed to a non-essential symbol, and the success or non-success of the barrier and cubicle systems depends not on the barrier or wall so much as on the incidental attention paid to hands and articles.

The method of "bed isolation," then, is nothing more than the carrying-out of the principles of asepsis and antisepsis in the case of certain diseases. The details are to be modified, if necessary, as we gain knowledge of the differences in the mode of transference of the different viruses. But certain principles are suitable for application in all cases, and should be applied whether the patient is at home or in hospital, in a special ward or in a "mixed" one.

I am, Sir, yours faithfully,

Welbeck-street, W., March 16th, 1912. F. G. CROOKSHANK.

CAVITATION OF THE LUNGS IN YOUNG INFANTS.

To the Editor of THE LANCET.

SIR,—The instances of hæmoptysis occurring in young infants referred to by Mr. P. Carruthers Watt and Sir R. Douglas Powell in the issues of THE LANCET for Jan. 27th and Feb. 3rd of this year are of some interest from the standpoint of the presence of cavitation due to tubercle in the early months of life. I have seen a large cavity in the lower lobe of the left lung crossed by a fibrous band at the age of 5 months. Death was due to tuberculous meningitis. In another case, of a child, aged 8 months, a cavity of the size of a walnut was present in the upper lobe of the left lung.

Interesting though this cavitation is at so early an age, whether complicated or not by hæmoptysis, there seems to me to be a danger that its presence should be taken as evidence of the not uncommon occurrence of phthisical cavities of chronic character in children. Such cavities are, in my experience, of great rarity in childhood. Needless to say, I speak especially, not of the early months, but of the early years of life. The cavities above referred to occurring in infants, like tuberculous cavities occurring later in the lungs of older children, were acute or subacute in character due to the rapid breaking down of caseous broncho-pneumonia.

Although well known, it is a fact which is deserving of emphasis in these days of examination of school children, that chronic cavities in the lungs of children are almost invariably bronchiectatic in nature. It may be interesting to add that considerable degree of dilatation of the bronchial tubes may be present under the age of one year. In a child aged six months I have seen half of the lower lobe of a lung affected with broncho-pneumonia thickly studded with dilated bronchial tubes, some measuring a quarter of an inch across. Broncho-pneumonia, especially apparently the broncho-pneumonia of measles, is the main cause of dilatation of the bronchial tubes in children.

The frequent reference in medical papers to the widespread infection of children with tubercle tempts a further remark that these references not uncommonly appear to manifest confusion as to what is meant by infection by tuberculosis. Some writers appear to assume that frequent infection of children with tuberculosis proves the frequency of chronic pulmonary tuberculosis. In children tuberculosis of the lungs is acute or subacute. During childhood the lungs appear to exhibit little or no power to prevent the rapid spread of infection within them, and death occurs before many months have passed.

I am, Sir, yours faithfully,

Sidcup, Kent, March 15th, 1912. THEODORE FISHER.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—In November last year you published a letter of mine in which I proved from the figures of my own practice that contract work paid for by premium per head and salary was much more lucrative than ordinary private work paid for by fees per visit. The publication of my discovery made but slight impression at the time, and apparently it failed to convince many of your readers that what was a particular truth as regards my practice was, indeed, a general truth of all practices. My contention then and now is that payment by premium gives better returns than payment for work done, and that in view of the falling sickness-rate the premium method is the only means by which our incomes can be maintained. I also tried to show that premiums can be adjusted to clients of all grades of income and of all degrees of ill-health. Throughout the controversy on the Act nothing has been more astonishing than the wide differences in the estimates made by various correspondents as to the equivalents of the two methods. Scarcely any two writers have agreed as to what premium *per capita* would be equivalent to a given fee per visit, and this is the very key of the whole position. It is practically agreed that if the Act would give us half-a-crown a visit or its equivalent premium we should be content. I think we are unanimous on that point, and it is about the only point on which there is complete agreement. The disagreement has arisen through the erroneous methods employed to find the equivalent in premium to this fee of half-a-crown per visit. Estimates have varied from 25*s.* to 6*s.*, the latter figure being the sum offered us under the Act. In my November letter I thought that 8*s.* 6*d.*, the premium paid by the Post Office, should be the amount paid under the Act, and we know that the Association has now fixed its demand on that sum. All this confusion of opinion has arisen from the absence of statistics. Actually the only trustworthy and useful figures before us are the returns of the societies, which give us the number of members and the total sick days paid for by them. But these returns do not give us the number of visits paid by the doctors attending, nor do they give us any idea as to the number of visits each sick member received. Sick days have the vaguest relation to sick visits. Practically no one keeps a record of the work he does for his clubs. Another difficulty in accepting the various estimates as equivalents arises through the knowledge that sickness-rates vary in different districts, at different times of the year, in different years, in different industries, in the two sexes, and at different ages. Not only does the sickness-rate vary, but so also does the personality of the doctor who makes the visits. So that every attempt to solve the difficulty has but added to the confusion—so far. Clearly the truth lies in this, that any estimate must depend on and vary with the personal equation—no two estimates could be exactly alike, because what I may call the "visiting habits" of no two doctors are alike. An average must be struck. That is what the Association has done. Is it high enough? Every general practitioner can put it to the test, in a way I will presently demonstrate.

I have within the last 24 hours lighted on an idea which to me seems likely to help us to solve this problem of equivalents. As I have said already, the equivalent arrived at will differ, slightly it may be, perhaps only fractionally, in every two practices. But every medical man would like to know what premium per head would give *him* the same return of income as his present visiting fees do. He is at a loss in his search for truth in all the maze of conflicting views that confront him at meetings and in the journals week by week. My plan will enable him to get very close to the mathematical truth. He will be able in half an hour to find how near to the average 8*s.* 6*d.* struck by the Association comes his own way of doing his work while charging for it at the rate of 2*s.* 6*d.* per visit.

Every practice contains so many clients at any given moment. A client is a person who either is now, has been, or may be a patient. What we want to know first of all is how much each client pays in the year to the doctor of his choice. Now here I must point out that no town doctor whatever, and very few country doctors, know how many clients they have, and herein is the root of many fallacious estimates. A client may never actually be a patient at all. For instance, an old client of mine was found dead in his back yard—he had never had a bottle of medicine in his life. If he had been a private client this practice would have derived nothing from him—there are such cases in every practice no doubt—but as a matter of fact this man as club client had been paying 6*s.* a year for 40 years to the practice. If, again, this man had lived in a town, and had not been a member of a club, no doctor would necessarily have known whose client he was. I make this illustration to show that very few doctors can really be sure how many clients they possess, and also to demonstrate the probability that there are thousands of people walking

the streets to-day, clients of no one knows whom. They are non-paying now, but will be premium-paying under the operation of the Act. So it comes to this, that no town doctor can tell how many clients it requires to furnish his income. But every doctor, of course, knows who have been, who are, and who are not his patients. And as one can see how impossible it is to arrive at the total of his *clientèle*, I have had to adapt my plan to the ledger as it stands now, and not as it may stand through the next five years.

We want to know how much we get from each client of our practice now while he is a private person, so that we can compare this sum with the amount we are demanding (8*s*. 6*d*.) from the same client when he becomes an insured person. Does every working-class private client of our practice now yield us as much as 8*s*. 6*d*. per annum? No one can answer, because no one knows all his clients. All that can be done in this direction is to see from one's books if the working-class *patients* have, over a period of four or five years, paid as much by fees as they would have done if they had each been paying us a premium of 8*s*. 6*d*. per annum. All that is necessary is to take from the ledger the names of 100 individual working-men patients *now alive*, add up what they have paid to the practice in 1908, again in 1909, 1910, and 1911. They must be the same individuals in each count. Then by making a total of the whole sum received from them in the four years and dividing it by 400 we get the average payment of each working-man private patient per annum. I venture to prophesy that every doctor who takes the trouble to make this simple investigation will find that the figure 8*s*. 6*d*. is on the safe side.

I should point out that this plan of taking patients' names instead of clients' (which one would do if one could) is really in my disfavour, inasmuch as many of one's clients are not on the ledger at all, are now paying nothing, but are soon to be insured and will pay a premium. Also one would get a truer equivalent with a larger count—say 500. The same plan can easily be carried out with other classes of patient. For instance, one might wish to know what premium would tally with a charge of 3*s*. 6*d*. per visit or a 5*s*. visit and so on.

In making up the count one ought in fairness to add to the list of patients a small percentage for clients who hitherto have not required service, but who are nevertheless potential patients of the practice and will pay premium under the Act. I would suggest 97 names of actual patients and add 3 for clients known or unknown and who pay nothing at all, of course, during the four years. It is not probable that the worked out average sum per head received per annum will be the same in any two practices. There will be fractional differences accounted for by variation in propensity to visit of different doctors—that must be expected.

I trust a good many of your readers will take the trouble to utilise my plan and bring forward their results. The more results we have the more readily shall we get an all-round general and true average premium for every rate of fee.

I am, Sir, yours faithfully,

B. HALL, M.B. Lond.

West Mersea, Colchester, March 11th, 1912.

To the Editor of THE LANCET.

SIR,—The medical profession, almost to a man, looks on the National Insurance Act with disfavour, and we are still searching for one beneficiary under the Act who has desired it, or, now that he has got it, is satisfied with it. Those of us, however, who have read Dr. Brend's recent articles on the subject[1] must have come to the conclusion that they formed one of the most carefully reasoned analyses of the Insurance Act which have so far appeared. Also, that there is something to be said for some of the views of the Chancellor of the Exchequer. Dr. Brend has apparently had the time and the ability to make a complete study of the Act in all its bearings, a thing which can hardly be said of most of the writers on the subject in medical and other papers.

At the same time, I have been a little bewildered, for if his statements are correct it is clear that the effects of the Act will not be so disastrous as we have hitherto supposed. Dr. Brend shows that the remuneration suggested is an increase upon existing fees, and that payments can be made to medical men from several other sources without touching upon the 6*s*. for medical benefit. Are these facts? The general practitioner is not in a position to estimate the effects of the Act, and some of the letters which have appeared in the press anticipating the ruin of medical practice have quite obviously been based upon errors. Dr. Brend points to the paucity of published statistics, but, as I have before suggested, cannot the British Medical Association give us some authoritative information? It has been collecting such information since the Bill was introduced, or, if not, it should have been doing so. What we want to know is this: What is the average amount which each person who will be insured under the Act pays for medical attendance now, and how many times does he see the doctor in the course of the year?

We may be quite sure that full information on these points is in the possession of the Chancellor of the Exchequer. But until we possess it ourselves, based upon full and reliable figures, we have nothing upon which to establish a claim for higher remuneration. We may ask for 8*s*. 6*d*., but until we can give solid reasons, and not vague generalisations why we should have it, we are merely ploughing the sands.

Dr. Brend's comments on the unsatisfactory way in which medical affairs generally are dealt with by the State will receive wide endorsement.

I am, Sir, yours faithfully,

Enfield, March 12th, 1912. R. HALDANE COOK.

[1] THE LANCET, vol. i., 1912, pp. 383, 447, 524, 598.

To the Editor of THE LANCET.

SIR,—Whether the decision of the British Medical Association to nominate members for the Advisory Committee of the National Health Insurance Joint Committee before the "six cardinal points" have been embodied in an amending Act or conceded by the Government is to be regarded as a climb-down, or otherwise, there can be no question as to its being decidedly diplomatic. I regret, however, that the Association has decided to entertain the question of adopting the capitation system of payment. My limited experience of contract work at *per capita* is that it is decidedly objectionable from every point of view, and that we should, if possible, wash our hands of it altogether.

It is admitted by the Commissioners themselves that the Act is sufficiently elastic to permit of payment by fees for actual services rendered. This is an ideal system, it is perfectly feasible, and may now be permanently and universally established if we unite as one man in demanding its adoption. The referendum taken by the Imperial Medical Reform Union in July last justifies me in saying that fully 95 per cent. of the general practitioners in England and Wales prefer payment for actual services rendered to the old and discredited capitation system.

We have now a grand opportunity for doing away with capitation payment for club work. I sincerely hope it will not be thrown away.

I am, Sir, yours faithfully,

GEORGE BROWN,
General Secretary, Imperial Medical Reform Union.

Callington, Cornwall, March 12th, 1912.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

A Curious Compensation Case.

A REMARKABLE case of importance to public bodies was heard recently at the Manchester assizes. The plaintiff had in his house a penny-in-the-slot gas meter. A penny became fixed in the slot and the meter became inoperative, and an officer of the Manchester corporation was asked to remedy the defect. In endeavouring to extract the coin he used his pocket-knife, and inadvertently left this knife on the ledge of the cupboard in which the gas meter was fixed. A boy, aged 5, was playing about the house, and about half an hour after the official had left the child was heard screaming in the street. It was then found that the child had the knife, and while swinging round a lamp-post had struck himself with it in the eye, whereby the sight of the eye was utterly destroyed and the eyeball had to be removed. The action was brought to recover from the corporation on the ground

that the injury to the boy was occasioned by the negligence of the official when he was acting as a servant of the corporation. After hearing evidence and arguments *pro* and *con.* the jury, in answer to questions from the judge, found that the officer, in the course of his employment and purposing to act on behalf of the corporation, was negligent in leaving the knife where he did, and that the accident was caused by such negligence. They assessed the damages at £125.

Hospital Saturday Fund.

The total amount raised for the Manchester and Salford Hospital Saturday Fund in 1911 was £7524, an increase of £358. £4400 were distributed among the hospital charities. It had been expected to realise more in a year of such good trade, but labour disputes had a serious effect upon the collections. It was urged that an attempt should be made during the present year to induce large employers of labour to encourage weekly collections in aid of the fund among their work people.

Instruction in Care of Infants.

The Board of Education in a memorandum dated November, 1910, directed the attention of local education authorities to the importance of instructing girls in the care and management of infants. The Board said that it is beginning to be widely realised that the teaching given to girls in the elementary day schools might with advantage be made more practical and be directed more definitely towards increasing their knowledge of the ordinary routine of domestic hygiene, including infant care. This work of teaching domestic hygiene has been in full operation since 1903. Instruction has been given in 103 schools to 8554 children in Standard V. and upwards.

Adolescent Insanity: Compensation Case.

An interesting case of "adolescent insanity" was recently before the Manchester County Court. A company applied for the termination or redemption of compensation payable to a girl, aged 17, on the ground that the girl was being maintained out of the public rates in Prestwich Asylum and that the disease from which she was suffering, "adolescent insanity," was not due to the accident in respect of which the compensation had been paid. The application was opposed by the South Manchester guardians, who were responsible to the county authorities for the maintenance of the girl. After hearing evidence the judge said that in a case of this kind the onus was upon the respondents of satisfying the court that the girl's present condition was due to this particular accident. Neither the assessor nor himself was so satisfied, and the compensation would therefore be terminated, with costs against the guardians.

Magistrates and Milk Prosecutions.

From the annual report of the medical officer of health for Nelson we find that in three milk prosecutions taken during the year only one conviction was obtained. Dr. Millar considers it regrettable that magistrates generally throughout the country do not appreciate more fully the importance of this question in relation to infant life. Any semblance of a defence is accepted as a pretext for dismissing a case, often with the result that local authorities are discouraged in their efforts to check adulteration, and the public continue to suffer. In view of the important position which milk occupies as an infant food, he considers it very desirable that an absolute standard of quality should be fixed, and any failure to reach such standard should be deemed an offence.

March 19th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

Professor John Joly, D.Sc., F.R.S., professor of geology in Trinity College, Dublin, has been appointed Huxley lecturer, and Mr. John Furneaux Jordan, M.B., F.R.C.S. Eng., Ingleby lecturer for this year. Dr. H. Percy Pickerill, formerly lecturer in dental histology and pathology in the University, and now director of the Dental School of the University of Otago, New Zealand, has been awarded the Cartwright prize of the Royal College of Surgeons of England for an essay on the Prevention of Dental Caries.

General Hospital: Retirement of Sir Thomas Chavasse.

The resignation of Sir Thomas Chavasse, the senior surgeon, will be a great loss to the General Hospital. He was appointed assistant surgeon in November, 1878, and honorary surgeon in December, 1881, making altogether over 33 years' service to the hospital. The following resolution was unanimously carried at a meeting of the board of management on March 1st:—

That this board has received with great regret the resignation of Sir Thomas Frederick Chavasse, and desires to record its high appreciation of the very able and courteous manner in which he has performed his duties of honorary surgeon to the hospital for the past 30 years, of the great skill and unwearied attention he has always devoted to the patients under his care, and of the interest he has at all times showed in the welfare of the institution generally. That the resignation of Sir Thomas Chavasse be accepted with great regret, and that in consideration of the eminent services of Sir Thomas Frederick Chavasse it be recommended to the next annual meeting of governors that he be appointed consulting surgeon to this hospital.

The Queen's Hospital.

The seventy-first annual report shows that the balance of expenditure over income last year was £5016 19*s.* 10*d.*, as compared with £5200 in 1910. The endowment of the hospital—about £40,000—is not large, the income from investments being only £1900. This is very little towards the annual expenditure of £16,000. The annual subscriptions for 1911 reached £3402, the largest amount since the foundation of the hospital. The legacies received amounted to £3342. Under the will of Mr. John Roderick the hospital will shortly receive £10,000, and in addition one-quarter of the residue of his estate. The committee, although unable to state with any certainty the effect of the National Insurance Act upon the finances of the hospital, calls the attention of subscribers to the fact that, whatever ultimately happens, the annual expenditure will not be decreased but will in all probability be increased by the new Act. It will not reduce the number of in-patients, because it makes no provision for the treatment of serious illness, nor will it probably reduce the number of out-patients appreciably, for the majority of these are married women, children, and other uninsured persons. The annual cost of insuring the hospital staff under the Act will be about £130. The number of in-patients treated last year was 3172, a decrease of 101 as compared with 1910, but an increase of 42 as compared with 1909. The decrease was due to the fact that several wards were closed for cleaning for a longer period than usual. The average stay of patients in hospital was 19·2, as compared with 18·8 days in 1910, and the average number resident daily in the hospital was throughout the year 159, as compared with 161 in 1910. The cost of each in-patient per week was £1 9*s.* 5½*d.*, as compared with £1 8*s.* 6½*d.* in 1910. The cost per bed per annum was £76 11*s.* 9*d.*, as compared with £74 4*s.* 6*d.* in 1910. The number of out-patients was 39,743, as compared with 39,365 in 1910. Regarding the appointment of an almoner it is reported that 260 cases passed through her hands. The treatment recommended for the cases referred to has been provided by the Charity Organisation Society and to a smaller extent by the City Aid Society and other institutions. There is no reason to suppose that any considerable financial saving has been made to the hospital, and the question whether the work of the almoner should be continued and the cost of it added to the standing charges of the hospital has been deferred until a further report of the work done has been received.

March 19th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Scotland and the National Insurance Act.

THE lull in medical interest in the National Insurance Act continues, but it is satisfactory to learn that in more than one place the doctors have set themselves to consider seriously the question of club practice and the position of the present holders of such posts in view of the possibilities of the future. It is understood that more than one unofficially constituted committee is investigating this thorny and difficult problem. The results will probably only be known when the Scottish Medical Insurance Council meets, and it cannot meet until railway travelling presents greater facilities than it does at present. Mr. Leishman,

chairman of the Scottish Commission, accompanied by Miss Paterson, the lady member of the Commission, visited Aberdeen on March 14th, and in the afternoon addressed a large public meeting in the town-hall presided over by the Lord Provost. Mr. Leishman had hopes that arrangements would be made with the doctors, as it was a mistake to think that all the doctors were against the Act; in some places they had sufficient to carry on the Act with. If the worst came to the worst, which he hoped would not occur, the medical benefit would be suspended and the money returned to the members. Steps are evidently being taken all over Scotland for the inclusion of insured persons in existing clubs or societies, or for the establishing of new societies in order to make the full benefits of the Act available to such persons. It seems to your correspondent that this movement, to which there is frequent reference in the daily press, has to be realised by the profession more fully than it would seem to be. Whatever the doctors may do, they cannot prevent this gathering into societies of those millions of persons who are dealt with in the Act, and those societies will have to be dealt with later, unless Providence interposes, and the Act is suspended by a new Parliamant appearing on the scene. The profession, however, can hardly reckon on such intervention.

The Marine Biological Association of the West of Scotland.

The management and policy of this association have come in for severe criticism at the twelfth annual general meeting of the association held last week. Approval of the report was eventually carried by 12 votes to 10, but much doubt as to the policy of the executive has certainly been created.

Strichen Hospital Affairs: Official Inquiry.

At a meeting of the Deer District Committee, held on March 2nd, there was a private sitting over the vexed question of the administration of the Strichen Infectious Diseases Hospital, which has been under consideration since June, 1910.[1] The results of the inquiry, as embodied in a report, ordered by the Local Government Board into the management and administration of the hospital, had been submitted at a previous meeting of the district committee, when the appointment of all the subcommittees was postponed, and also consideration of the report until March 2nd. The report was considered *in camerâ*. The terms of the report were briefly as follows:—The Commissioners appointed by the Local Government Board to make inquiries were Mr. Alexander McKinna and Dr. Thomas F. Dewar. The inquiry was held in the Victoria Hall, Maud, on Tuesday and Wednesday, August 29th and 30th, 1911. The points of inquiry related to the following matters. 1. The case of Dorothy Henderson, Longside Manse, who was said to be removed home from the hospital while still in an infectious state, thereby conducing to other four cases of scarlet fever. 2. The case of Eliza Leal, whose case was diagnosed as scarlet fever on her entering the hospital, and who developed symptoms of scarlet fever 19 days after admission to hospital. 3. Alleged alterations in hospital books. 4. Alleged substitution of hospital books. 5. General administration of the hospital. 6. Visitation of the hospital by members of the subcommittee. 7. Relation of the convener of the hospital committee to the staff. 8. Hospital regulations. With regard to the points upon which Dr. G. S. Trail is directly or indirectly implicated, the Commissioners completely vindicate and exonerate him from any blame in the matters. They find: "The management of the hospital seemed to be everything that was desired." "The buildings were clean and in good order and the patients seemed to be well nursed and attended to." The Commissioners earnestly recommend that in future all the members of the hospital committee should take part in the visitation of the hospital and thus acquire direct and personal knowledge of the details of its administration. They go on to say that, much to their regret, they feel bound to give it as their conviction that the unhappy and unseemly circumstances which have been so continuous a feature of the administration of the hospital from June, 1909, until now, are essentially associated with the personal attributes of the convener of the hospital subcommittee. While fully appreciating the fact of his devoting his time and energy to its affairs, and conducing in no small part to the general success of the hospital's working, and while believing that throughout his actions he has been actuated by what he doubtless considered his duty in regard to its supervision, they no less definitely are of opinion that the difficulties involving Dr. Trail and the matron, and in less degree the district clerk, in much distress of mind and prolonged unhappiness, have arisen from his action. With regard to the gravest of them, where Dr. Trail and Miss Clark are charged with substitution of hospital books, or complicity in such substitution, Mr. Watt is neither associated with, nor is his action endorsed by, any of his fellow members of the subcommittee. With regard to hospital regulations the Commissioners, while not feeling called upon to suggest any amendment of these regulations, desire to express their opinion that they should not be interpreted in so stringent a fashion as the minutes of the hospital subcommittee of June 17th, 1909, and March 26th, 1910, would suggest. Mr. John Watt, retiring convener, protested against the finding of the reporters of the Local Government Board, stating that he did not admit the accuracy of certain statements on which the conclusions of the report were based.

The Practitioners at Dunfermline and the Friendly Societies.

The contract between the Dunfermline medical practitioners and the Friendly Societies closes at the end of the current month. This position of affairs ensues upon the local medical men raising their terms from 4*s*. 4*d*. to 8*s*. 8*d*. annually per member and intimating their resignation unless their terms were accepted. Representatives of the Friendly Societies, meeting as a committee, accepted the resignations, and it was decided by the Oddfellows to accept the services of two Glasgow medical men. The other Friendly Societies in Dunfermline have not yet decided upon a course of action.

March 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Insurance Act.

AT the mass meeting of the medical profession held in Dublin last June the care of the negotiations with the Government and others as to the terms of the Insurance Bill was committed to a joint committee of the British and Irish Medical Associations. This joint committee has now issued a report to the practitioners of Ireland detailing its labours, discussing the Act, and suggesting future action. The main activity of the committee seems to have been directed to a policy for which it had no mandate from the profession—the restoration of medical benefits to the Bill as applied to Ireland. In this attempt it failed. The report now issued deals fully with the provisions of the Act as applied to Ireland, and will prove of great value as regards future action. Although the Act as it applies to Ireland does not include medical benefits, there are, it appears, two ways open by which medical attendance may be secured—(1) as additional benefit under the terms of the Act and the regulations of the Commissioners; (2) by societies independently of the Act. Attempts were made to secure that medical benefits, if granted as "additional benefits" in Ireland, should be administered by the Insurance Committees, not by the societies, but Parliament added the words "unless the Irish Commissioners direct otherwise." The committee suggests that, in the event of the Commissioners so directing, it may be wise for Irish practitioners to decline all service under the Act. With regard to remuneration for medical services, the committee states that all arrangements lie between the Insurance Committees and local Medical Committees. It is properly affirmed that it is impossible now to give any considered opinion as to what the amount of remuneration should be. Rates must vary in different districts, and must be higher in the case of deposit contributors than, for instance, of selected members of a good society. The points for and against payment by capitation and by work done respectively are well set out in the report. The committee considers it very unsatisfactory that there is no appeal from the decision of the Commissioners. It suggests that the profession should insist on the following as minimal conditions, without which medical men should not accept service under the Act: (1) a total income limit for those entitled to medical benefits; (2) free choice of doctor; (3) all medical certificates to be issued by medical attendant; (4) administration of medical

benefits only through the Insurance Committees; (5) provision for extra remuneration for special services. It is intended shortly to summon a representative meeting of the profession, to which local Medical Committees should send delegates. It is also intended to form a Central Medical Committee consisting of representatives of the various medical societies, the universities, and the medical corporations. The committee urges the profession to organise in county committees without delay. It also asks practitioners to sign a pledge declining to enter into any arrangement for service under the Act except through a local Medical Committee.

New Labour Wards at the Rotunda Hospital.

The new labour wards at the Rotunda Hospital are now ready, and should render more easy the management of labour by modern methods. The suite consists of five rooms and a kitchen, a dressing-room, a waiting ward, the labour ward itself, a clerical room, and an isolation labour ward. The waiting ward and the labour ward are of the same size, the former being furnished with 12 beds. The two wards are fitted with similar hot and cold sterilised water-supplies, so that in case of need the waiting ward may be used instead of the labour ward. The floor of both rooms is of white mosaic, and the walls, to a height of 8 feet, of green mosaic. The rooms are well lighted, well ventilated, and lofty.

Royal Victoria Eye and Ear Hospital, Dublin.

The annual meeting of the Royal Victoria Eye and Ear Hospital was held last week. The report showing that the accommodation of the institution no longer meets the public demands upon it, it was proposed to add to the building so as to provide for 18 additional beds.

Derry Water-supply.

It appears from the report of a meeting of Derry water and fire brigade committee of the City Corporation, held on March 12th, that, notwithstanding all the rain of the present winter, the city reservoirs are still 64,000,000 gallons short of being full, with the result that there is a shortage of 28,000,000 gallons as compared with the corresponding period of 1911. As a result, the citizens have been placed on a restricted allowance in the hope of building up a good reserve so as to avoid a repetition of the water famine of last summer. It is clear that a more extensive supply is needed, as it is necessary, so early as at present and during a season of exceptional rain, to curtail the supply of domestic water.

The Provision for "Sanatorium Benefit" in Belfast.

The question is rapidly coming to the front, How is "sanatorium benefit" under the Insurance Act to be provided for in Belfast? At the present time the Belfast guardians have a magnificent sanatorium at White Abbey, near Belfast, which with its buildings and beautiful grounds of 33 acres cost £39,138, and which contains accommodation for 265 destitute consumptive patients. In the Forster Green Hospital for Consumption there are 76 beds (39 for men, 37 for women), and in that institution 35 beds are reserved for patients sent in on the recommendation of the medical officer of health of the city and the public health committee, these being paid for out of the rates. There are also ten consumptive beds at the convalescent home in connexion with the Royal Victoria Hospital—that is, altogether there are 351 beds available for "sanatorium benefit." Now, in Belfast during 1910, there were 825 deaths from phthisis, giving a mortality of 2·1 per 1000. Further, 929 cases of tuberculosis of the lungs were notified, pursuant to the Tuberculosis Prevention (Ireland) Act, 1908, and, in addition, 244 cases were notified voluntarily, making a total of 1173 cases dealt with by the Public Health Department. It is therefore clear that 351 beds for "sanatorium benefit" would not be enough, while under the Act as it stands at present the large Abbey Sanatorium would not be available, as Poor-law authorities are entirely outside the new insurance measure. Hence the Belfast guardians have waited upon the corporation health and finance committees with a view of obtaining for the Belfast district a portion of the capital sum allocated by Parliament for the erection of sanatoriums, as well as the yearly grants available for "sanatorium benefit" under the Insurance Act. The Belfast corporation will have to acquire the Abbey Sanatorium, becoming the responsible authority for it, having regard to the Insurance Act. If this was done an arrangement could be made for the treatment of non-insured and destitute consumptives by the guardians with the corporation similar to that already existing at Purdysburn for treatment of cases of infectious disease. If this is not done how is the Abbey Sanatorium to be maintained, and how is the city corporation to fulfil its duties as the health authority towards the consumptives, and finally, what action will the local Health Committee (to be formed under the Insurance Act) take? It is satisfactory to know that the joint corporation and finance committees are very carefully considering the matter, which presents considerable difficulties.

March 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Election at the Academy of Sciences.

IN the Section of Medicine and Surgery of the Academy of Sciences a vacancy has arisen through the death of Professor Lannelongue. Many candidates of high rank presented themselves. The proper authorities presented in the first place M. Charles Richet, the well-known physiologist, professor at the Faculty of Medicine and member of the Academy of Medicine, and in the second place M. Delorme, Médecin Inspecteur-Général of the Army Medical Service; M. Le Dentu, M. Lucas-Championnière, M. Pozzi, and M. Reclus, all members of the Academy of Medicine. Two ballots were required. At the first M. Charles Richet obtained 26 votes, M Lucas-Championnière 25, M. Pozzi 4, M. Le Dentu 3, and M Reclus 1. At the second, out of 60 votes cast, M. Lucas-Championnière gained 32 and was declared elected. M. Charles Richet had 26 and M. Pozzi 2. The newly-elected academician is honorary surgeon to the Hôtel Dieu, a member of the Academy of Medicine, a former president of the International Society of Surgery, and is one of the most brilliant and authoritative exponents of French surgery. His first work was the study and the dissemination of antiseptic surgery—that is to say, of scientific surgery as initiated by Lord Lister. The application of scientific surgical doctrine to current surgery constituted his second work. To make this application it was necessary completely to transform the ordinary practice of surgery, and to formulate a technical method in place of the varied procedures of traditional surgery which were devoid of scientific guidance. The most important of his writings treat of trephining under the direction of cerebral localisation, the radical cure of hernia, the removal of the tarsal bones, and the treatment of fractures by mobilisation and massage. Moreover, M. Lucas-Championnière is the director of the *Journal de Médecine et de Chirurgie Pratiques*, in which he has published numerous surgical studies.

The Academy of Medicine.

The Academy of Medicine on March 12th elected M. Mesureur, Director of Public Assistance, Paris, a member in the free section in place of M. Henri Monod, deceased. M. Mesureur was elected by 54 votes, as against M. Castex, who received 25 votes.

A Protest against the Superior Commission for the Reform of Medical Studies.

A great meeting, organised jointly by the Corporate Association of Medical Students and the Syndicates of Practitioners, took place on March 9th in the hall of the learned societies The meeting unanimously protested against the composition of the Superior Commission for the Reform of Medical Studies, on which the practitioners are in an excessive minority, and which admits no delegates from the professional associations of students of medicine. They also protested against the mode of nomination of this commission, all the members of which are arbitrarily appointed by the Minister and not elected by their professional constituencies. They further protested against the *modus operandi* of this commission, whose duties are determined by no official decree, while it has delegated all its powers to a permanent subcommittee entirely in the hands of the administration; and against the mode of discussion of the commission, which from its first session regulates examinations bearing upon a course of instruction that it has not as yet defined.

The practitioners and the students finally demand the formation of a Superior Medical Council.

The Leave of Tuberculous Officials.

An article in the Finance Law of 1911 laid down that a law to be passed before Dec. 31st, 1912, would provide long leave of absence, with treatment and carrying the right to a pension, to officials of the public administration affected with tuberculosis. With a view of giving effect as quickly as possible to this humane intention, the Minister of Finance has appointed an Inter-Ministerial Commission, on which is imposed the task of collecting the necessary information on the subject and preparing a draft to be submitted to Parliament. As the question interests all the great administrations, this commission comprises officials of all the Ministerial departments.

The Preparation and Therapeutic Utilisation of Sulphurated Oils.

On Feb. 28th M. Huerre brought this subject before the Société de Thérapeutique. Sulphurated oils are obtained from the combination of sulphur and vegetable oils by the action of heat. The sulphurated castor oil is prepared by gradually raising the temperature of a mixture of precipitated sulphur and castor oil up to 225° C. It is a viscous liquid, containing from 6·5 to 7 per cent. of sulphur, and is very soluble in a large number of solvents, ethers, essences, acetone, chloroform, &c. This solubility permits of the preparation in a very manageable form of numerous medicaments used in dermatology, such as salicylic, pyrogallic, and chrysophanic acids, and resorcin in a sulphurated organic combination, which is always better tolerated by the skin than sulphur itself. These preparations have given good results in the dermatoses in which sulphur is indicated—pityriasis of the scalp, seborrhœic eczema, acne, &c.

The French Association of Medical Inspectors of Schools.

A new association has just been formed, the object of which is to bring into relation all the school physicians in France, to defend their professional interests, and to study questions relating to their functions. It consists of members (medical inspectors of French schools) and of associate members (school medical officers of the French-speaking countries and medical men generally interested in school medicine and hygiene). The annual subscription is 5 francs. The association is to meet this year at the end of May. The organisation of medical inspection in France and physical education will be on the orders of the day. The Congress will close with a fête organised by the medical inspectors of schools of the Seine.

The Collège de France.

The general assembly of professors of the Collège de France has forwarded for the selection of the Minister as candidates for the chair of histology (formerly the chair of anatomy, now vacant by the resignation of M. Ranvier) the names of first, Dr. Nageotte, professor at the École Pratique des Hautes Études, and second, Dr. Jolly, adjunct director of the same school. Two ballots were requisite, for at the first each candidate obtained 15 votes; at the second M. Nageotte obtained 18 votes and M. Jolly 15.

March 18th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

A Tribute to the Memory of Lord Lister.

THE news of Lord Lister's death was received here with the utmost regret by the medical profession, and the Gesellschaft der Aerzte at once decided to hold a special meeting for the delivery of an address in which the ever-memorable results of his labours should be duly appreciated. Professor Fränkel, who was the chief speaker on this occasion, did not try to say anything new to his audience, who were all well acquainted with Lister's achievements, but he pointed out that some years before the introduction of antiseptic surgery two Austrian medical men had called attention to the importance of cleanliness and the avoidance of external contamination in the treatment of surgical diseases and wounds. One of these was Semmelweis, who in 1842 tried to eliminate the dangers of infection from obstetric practice, and the other was von Kern, who at the same time maintained that wounds became infected from the outside and might be kept healthy by covering them. Professor Fränkel observed that there was an important difference between these two and Lord Lister. Whereas his predecessors had merely a more or less intuitive notion of the right thing, Lister was not only capable of thinking out the whole problem, but he also found means of putting his ideas into practical execution. Professor Fränkel's audience included many distinguished personages, and his discourse had a very favourable reception.

Scarcity of Children's Hospitals in Vienna.

In this city there are far too few beds available for the hospital treatment of sick children, and it is a constant complaint of all medical and social workers that for this reason it is difficult to deal adequately with infectious diseases. The matter was recently brought into general notice by a letter in the public press, and the correspondence ensuing thereon disclosed the curious fact that in Vienna there are three hospitals intended for the treatment of children, but closed for lack of funds. Under the wills of three different persons, each of whom had bequeathed a certain sum for that purpose, three hospitals, one with 30 beds, one with 50 beds, and one with 100 beds (the last named is not completed yet), were built in the expectation that the funds for maintaining them would be forthcoming when required. In former years such hopes were justifiable, but nowadays it seems that charitable people are less frequent. So we have only the children's clinic with 56 beds, the Wilhelminen Spital with some 300 beds, one institute with 40 beds in the situation where the children's clinic formerly was, and two new hospitals which have been erected for diseases of children within the last five years, one with 100 beds and one with 120 beds. Moved by these unsatisfactory conditions, Mr. von Guttmeun has recently handed over a sum of three millions of kronen (£120,000) to the Jewish community of Vienna, for the purpose of erecting and maintaining a children's hospital on a large scale, for patients of all nations and creeds, and he has given permission that all other funds granted for the purpose of children's hospitals may be united with his grant, as he does not wish his name to be associated with any ward or cot or building.

The Dispute between the Rettungsgesellschaft and the "Medical Organisation."

As was explained in this column on Jan. 13th last, serious differences of opinion had then arisen between the "Medical Organisation" of Vienna and the Rettungsgesellschaft (First Aid Association), also of this city. Things went so far that a boycott of the association by the Vienna practitioners was contemplated. The main objects of conflict were questions of principle. The Rettungsgesellschaft was unwilling to regulate its scale of medical fees, and its other rules as regards medical service, according to the lines laid down by the Medical Organisation. The controversy was so serious that several lawsuits were commenced, but the two parties fortunately came to an understanding before the courts had an opportunity of intervening, and all quarrels have now been amicably arranged. This result has been received with great satisfaction by the profession in general, for the dispute between the two medical corporations was regarded by all as most inappropriate, to say the least. The Medical Organisation is now recognised by the Rettungsgesellschaft as being the duly accredited representative of the medical practitioners, and the latter's scale of fees has been satisfactorily adjusted.

A Popular Lecture on Tuberculosis with Kinematographic Illustrations.

The board of health recently made an interesting experiment by using the kinematograph to illustrate a popular lecture on the nature, spread, and prevention of tuberculosis. In the course of this lecture, which was intended for the information of the people, Dr. Winter, one of the public health officers of Lower Austria, showed moving pictures that represented first the unhealthy surroundings of the poorer classes which are so favourable to the communication of the disease, and, secondly, the hygienic conditions of a sanatorium. The pictures were at the same time explained by the lecturer. Several pathological specimens were then shown, including the early stage of lupus, its treatment, and the favourable results obtainable in early cases, as

well as examples of tuberculosis of the joints and bones. The methods of treatment in the open-air sanatoriums were demonstrated, and the public were shown how a good supply of fresh air could be insured by proper arrangement of the windows. This novel form of popular instruction in medico-hygienic matters will no doubt prove useful, for a combination of lectures and visual demonstrations has many advantages over purely theoretical teaching.

March 16th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Alessandro Codivilla.

THE Bologna school has lost one of its chief ornaments in this accomplished and versatile surgeon, to whom orthopædy is indebted for not a few of its most ingenious and effective appliances. A Bolognese by birth, he was educated at the celebrated Archiginnasio, enrolling as a student of medicine and graduating with distinction in 1886, when in his twenty-fifth year. In 1889 his skill in the operating theatre and his expository power in the lecture-room procured him rapid promotion in various surgical institutions, notably in those of Macerata and Imola, till in 1890 his fertility of resource and well-nigh uniform success in relieving the defects, infantile, congenital, or accidental, of the apparatus of locomotion, marked him out as successor to Professor Panseri as director of the famous Istituto Rizzoli in Bologna. Here he found his special *métier*, and so improved on the traditions, already honourable, of the institution as to make it a centre not only of relief or rehabilitation to its young inmates but of instruction, not to say inspiration, to those interested in orthopædy, theoretical and practical. At the periodical congresses of surgery his presence never failed to enhance the interest and value of the proceedings, and not a few of his papers, read and discussed on these occasions and since published in a permanent form, have passed into the literature of the profession. His success in treating or in rehabilitating the wounded from the seat of war in Tripoli, conveyed as many of these were to Bologna so as to be under his eye, evoked the admiration of his colleagues as well as the gratitude of the patients, and proved a manifest consolation to him during the painful illness to which he has so prematurely succumbed.

The Guido Baccelli Ambulance at Tripoli.

Of this institution, called after its initiator and organiser, known throughout Italy as "Dean of the Faculty of Medicine," there are four sections devoted to the care and cure of the natives injured or ailing at the seat of war. All the indigenous population of Tripoli are eligible for treatment; first, in the Medical Section, directed by Captain Scaloso of the Army Medical Staff; second, in the Surgical, directed by Captain Bevacqua, of the same corps; third, in the Ophthalmic, directed by Captain Mazza; and fourth, in the section set apart for oto-rhino-laryngeal maladies, directed by Captain Tonietti, also, like the three others, of the Medico-Military Department. The services offered are gratuitous, available every day of the week from 9 to 12 A.M. and from 4 to 6 P.M. In addition to this there will soon be opened a special "ambulatorio" for syphilitic diseases, to be superintended, like the four sections above referred to, primarily by General Salsa, and secondarily by the various "servizi sanitari" and the *personnel* of the "Amministrazione degli Instituti Ospedalieri." Premises for "first aid" are well advanced in construction. Further, in the same laudable direction there will shortly be made available a set of rooms for disinfection, for baths, for mortuary requirements, including necropsy, with laundries, and accommodation for the *personnel* of the administration. All these additions to the "Ospedale Civile," fully equipped and up to date in every particular, will soon be in working order, constituting a substantial boon to the native population and of happy augury for the future of the Tripolitania, when, as is anticipated, it will come finally under the legislative control of the Italian kingdom.

March 14th.

THE CREMATION SOCIETY OF ENGLAND.—The annual meeting of subscribers will be held at 20, Hanover-square, London, W., on Wednesday, March 27th, at 3 o'clock.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The New Austro-Hungarian Hospital.

THIS institution was erected at the cost of £65,000, a large proportion of which was contributed by the Austro-Hungarian Government. At present it has a State subsidy of 70,000 kronen per annum (a krone = 10*d.*). It is equipped with every modern convenience and requisite and commands one of the finest sites in the metropolis. The thing that especially strikes a visitor is the abundance of space and light in the whole hospital. There is not a single obscure corner; everywhere plenty of light floods in through the many high, broad windows. The whole establishment is constructed on hygienic and sanitary principles, and the cleanliness in a city like Constantinople is particularly worthy of mention. The view from the windows over the Bosphorus, the Asiatic shore, and the undulating cypress-clad hills all around is superb. The material for the building, as well as the internal surgical and medical equipment, were furnished by firms in Vienna. The hospital has 60 beds, but this number can be increased. Half of the hospital is occupied by the surgical department; the other half is for medical cases; and there is also a separate building for infectious cases. A suite of rooms is reserved for private baths for the outside public. Two members of the medical and surgical staff, Dr. Schuster and Dr. Ehrlich, possess diplomas from the University of Vienna. A lady doctor, Fräulein Frisch, is also on the staff. Women are, of course, not allowed to practise medicine in Turkey, but this hospital is on Austro-Hungarian territory and outside the Ottoman medical jurisdiction. Fräulein Frisch is doing excellent work under the protection of her Government. The hospital possesses two automobiles, one for ambulance purposes and one for the use of the staff.

The War Refugees from Tripoli.

It has been found that almost all the refugees from Tripoli are suffering from various chest affections. Quite a large number have developed pneumonia, and bronchitis is very common. There are also several cases of phthisis. Investigation showed that the refugees, mostly Arabs, are unable to stand the wintry weather prevailing in Constantinople at present. It has therefore been decided to send all the sufferers further south, where the climate is warmer, to such places, for instance, as Beirut. The Ottoman Government has granted a special sum of money for this purpose.

Lectures on Hygiene.

In order to spread among the population a knowledge of hygiene and sanitation the medical authorities of the hospital of Gulhaneh, in Stamboul, have decided to arrange an exhibition and to deliver a free course of lectures. In the rooms to be assigned for this exhibition there will be on view a large number of statistical tables and sketches showing the causes of disease, as well as microscopical preparations. It is intended also to give instruction in the bringing up of children and in the care to be taken during an outbreak of infectious diseases. These lectures should help to remove the gross superstition and ignorance of the lower classes of the population, provided, of course, that the design is not left to the chances of kismet.

The Recent Fires at Stamboul and Balat.

The private subscriptions for the sufferers from the recent great fires in Stamboul and Balat have produced the sum of over £75,000, a large proportion of which came from Great Britain. Exceedingly little of that sum has been distributed among the burnt-out. Continual complaints are brought forward to the effect that the destitute are starving and are exposed to the inclemency of the wintry season without receiving any help whatever. If some small assistance is given here and there, the formalities are so intricate that the poor are losing heart completely. I have made inquiries and was told that the bulk of the contributions is reserved for the construction of fire-proof dwelling-places. In the meantime the need of the burnt-out is very great indeed Mention should be made of the prompt and generous help given to the sufferers by the British Ambassador, Sir Gerard and Lady Lowther.

Feb. 20th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

The Substitution of Saccharine for Sugar in Prepared Foods Prohibited.

¶ THE Board of Cabinet Officers of the United States Government charged with the enforcement of the pure food laws has rendered a final decision against the use of saccharine in prepared foods, thus settling a controversy of almost four years' duration. This decision is based on the Remsen Board's report that the addition of saccharine to food, as a substitute for sugar, "must be regarded as a substitute involving a reduction in the food value of the sweetened product, and hence a reduction in its quality."

Factory Investigation.

In the New York State Senate, on Feb. 28th, a Bill to continue the Factory Investigation Commission for another year and to give it an additional appropriation of $60,000 was passed. The object of this Commission, which was created last year after a disastrous factory fire in New York in which many workpeople were killed, was to investigate the conditions prevailing in factory buildings in the city.

The Quarantine Situation in New York.

The Governor of New York State has nominated Dr. Joseph J. O'Connell, of Brooklyn, to succeed Dr. Alvah H. Doty as port health officer of New York. Though a distinguished neurologist, Dr. O'Connell is without experience, so far as is known, of sanitary or quarantine problems. Assistant Surgeon-General L. E. Cofer, of the Public Health and Marine Hospital Service, after explaining recently at the New York Academy of Medicine that 44 ports of the United States were under exclusive Federal control, pointed out that, on emergency—e.g., the prevalence of cholera last summer—the Federal Government invariably sent to New York and the other ports under State control a surgeon of the Public Health and Marine Hospital Service to supervise matters. Mr. William Williams, Commissioner of Immigration, also a Federal official, at the same meeting of the Academy, pointed out that all immigrants, after the State inspection, have to undergo detention until any latent disease has had time to develop, and the immigrant is not permitted to go ashore until it is certain that no such disease exists. While the health office of the port of New York, therefore, remains a sought-out pecuniary prize, the salary being £3200 per annum, the importance of the appointee to the welfare of the community is less than has hitherto been thought. The other ports of the United States under local control are Baltimore, Providence, Philadelphia, and Boston, in all of which the Federal Government intervenes in time of need; and all will in time become subject to central control alone. Dr. Doty's services are not to be lost to New York, for, as health officer of the port, he was, *ex officio*, a member of the Department of Health, and he has now been elected a member of the advisory board of the Department.

Vindictive Baby Poisoning.

A young woman-of-all-work in the Infants' Hospital of the Brooklyn Nursery was arrested on Feb. 24th on the charge of having poisoned eight babies in the institution by putting oxalic acid in their milk bottles. The young woman, who has a baby of her own, confessed the crime, stating, however, that she had no intention of killing the infants, but merely wished to create a disturbance and trouble for the nurses in return for slights she had received. Twenty-two other infants in the hospital escaped by the accident of a door slamming while the woman was putting the acid into the bottles, frightening her so that she withdrew from the refrigerator in which the bottles and sterilised milk were kept. The woman's antecedents are bad and she is pregnant.

A Doctor's Suit Against the Mayor of New York.

Some time ago Mayor Gaynor, of New York, was shot while he was on the deck of a steamship about to sail for Europe. As the steamer docked in the North River, on the New Jersey side, the victim was taken to a New Jersey hospital. The house surgeon of this institution rendered a bill for £1500. The New York Board of Aldermen tendered £500, which sum was refused. The surgeon now claims £2600, and when the mayor recently went to Atlantic city (a popular New Jersey seaside resort) had a summons served upon his patient. A summons of this kind cannot be served across State lines. The suit will be contested on the ground that the surgeon was only accidentally called into the case in the emergency, and was not engaged either by the mayor or any of his friends.

Portrait of Dr. Wyeth Presented to the New York Academy of Medicine.

On the evening of Feb. 15th a portrait by Mr. J. Campbell Phillips of Dr. John A. Wyeth was presented to the New York Academy of Medicine. The presentation was made on behalf of the Academy by Dr. Simon Baruch.

Outbreaks of Cerebro-spinal Meningitis.

Dr. Abraham Sophian, of the New York Department of Health, has returned from Texas, where an epidemic of spinal meningitis has been raging, 300 cases having occurred in one month in the city of Dallas alone. About 45 per cent., rather more than half the usual percentage, of the cases were in children. Dr. Sophian attributes the success in stamping out the epidemic to the promptness with which patients, rich and poor alike, were removed to hospitals, and to the use of the antimeningitis serum prepared by the Health Department in New York, with which he inoculated 3500 patients. The general mortality was about 10 per cent., but only from 5 to 6 per cent. in children, the percentage being raised by the large proportion of patients over 60 years of age and the many negroes infected.—Cerebro-spinal meningitis is also reported to be spreading in Oklahoma. The disease has appeared in 30 counties of the State and there have been 187 cases with 67 deaths.

Mortality among Alaska Indians.

Passed Assistant Surgeon Foster, of the Public Health and Marine Hospital Service, returning from a tour through Southern Alaska, has informed Congress that at least £14,000 will be required for additional medical work among the Indians of that section. The birth-rate for the past five years and seven months has been 72·3 per 1000, while the death-rate has been 85·4. During the last ten years there has been a decrease in the Indian population of about 14 per cent. The large mortality is due mainly to tuberculosis, which always attacks tribes recently rescued from savagery and put into civilised clothing and dwellings. If the present proportion of deaths to births is not modified, the tribes will be extinct in about 60 years.

Vaccination and Small-pox in the Philippines.

Recently-published statistics show that small-pox has been practically eradicated from the United States Army in the Philippines. In 1898, 10,000 American soldiers in the islands had 76 cases of small-pox, a case-rate of 7·67 per 1000; deaths numbered 21, a mortality-rate of 2·12 per 1000. In 1910, among 12,277 soldiers, only 2 cases of small-pox occurred, and both recovered. In the earlier years of American occupation many of the soldiers were volunteers, among whom it was difficult to enforce vaccination. Moreover, the vaccine brought from San Francisco and Japan became inactive in the warm climate. On the introduction of fresh lymph from Carabao calves in 1900 the great prevalence of small-pox among the troops quickly subsided.

March 9th.

DONATIONS AND BEQUESTS.—Among the large bequests under the will of the late Lord Wandsworth are the following:—£10,000 to be used for medical research "as my friend and doctor Sir William Bennett shall decide is best," £5000 to the Bolingbroke Hospital, Wandsworth Common, S.W., £1000 to the London Hospital, £1000 to St. George's Hospital, and £500 to the Brompton Hospital for Cancer.—The late Mr. James Cook has left a sum amounting to nearly £50,000 to be equally divided between the Taunton and Somerset Hospital, the Bridgwater Infirmary, and the Royal West of England Sanatorium.—The late Mrs. Margaret B. Swaine has left her residence, The Highlands, Bexhill on Sea, to St. George's Hospital for a convalescent home. The residue of the testatrix's estate will be used for the endowment of such home if the hospital authorities accept the bequest.

Obituary.

SIR RICHARD BRAYN, M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.,

LATE MEDICAL SUPERINTENDENT OF BROADMOOR CRIMINAL LUNATIC ASYLUM, AND HOME OFFICE EXPERT IN LUNACY.

Sir Richard Brayn, late medical superintendent of Broadmoor Criminal Lunatic Asylum and Home Office expert in Lunacy, whose death, after a short illness, in his sixty-second year, we announced last week, was the son of Mr. T. G. Brayn, of Market Drayton, Salop. He received his medical education at King's College Hospital, where he was successively first year, second year, and senior scholar, besides winning prizes in many special subjects. In 1875 Mr. Brayn was appointed assistant surgeon to H.M. Convict Prison, Portsmouth, thus commencing what was to be a distinguished career in the prison medical service, and more particularly in connexion with criminal lunacy. He later became assistant surgeon at H.M. Prison, Millbank, and in 1879 was promoted to medical officer of H.M. Prison, Pentonville; in 1882 he was moved to the invalid establishment at Woking, where he also had charge of the insane convicts.

In 1889 Mr. Brayn was appointed Governor and medical officer of the Female Convict Prison at Woking, which he retained until 1896, when he succeeded Dr. David Nicolson as medical superintendent of Broadmoor Criminal Lunatic Asylum on the latter being appointed Lord Chancellor's Visitor in Lunacy. He held this onerous and responsible post for over 14 years, becoming an acknowledged authority on criminal lunacy and one whose opinion was held in high esteem in all such matters. He was an excellent administrator and was indefatigable in his work, always having the interest of the asylum, both patients and attendants, at heart. He retired in 1910, the constant anxiety and responsibility having commenced to tell upon his health, but he was appointed, on his retirement, a member of the Council of Supervision, thus maintaining his interest in the asylum. He also continued to act as mental expert to the Home Office, which position he held up to the time of his death. He received the honour of knighthood in 1911.

He married Miss Laura Negus, daughter of Deputy Inspector-General Fysher Negus, R.N., who, with a son and a daughter, survive him, by whom, as also by his many friends, he will be greatly missed. The funeral took place at Southsea on March 15th, the first part of the service being held at St. Peter's, Somers-road. Amongst those of his old friends were Dr. Nicolson, Dr. Herbert Smalley, Medical Inspector of H.M. Prisons, who also represented the Prison Commissioners, and Dr. John Baker, the medical superintendent of Broadmoor Asylum.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Albert Schütze, of the German Red Cross Society, who had been serving in the Turkish Red Crescent Ambulance Hospital at Gharian, where he was in charge of the medical side, from typhus abdominalis, aged 39. He had distinguished himself as a bacteriologist in the Berlin Institute of Infectious Diseases, and had acquired the rank of professor of the university. During the Russo-Japanese war he served with the German Red Cross expedition, and was afterwards appointed by the Berlin city authorities head of the newly established Bacteriological Institute in connexion with the Moabit Hospital.—Dr. Windels, medical member of the Prussian judicature, aged 64. He was held in high esteem by the medical profession from his sympathetic action in its behalf.—Two German medical men have very recently died as the result of dissection wounds: Dr. Stark, of Lörrach, and Dr. Hermann Hahn, prosector of the Anatomical Institute of the University of Munich.—Dr. Andreas Mordtmann, one of the most popular medical men in Constantinople, where he had been for something like half a century. His father, who came from Hamburg, was for many years in business in Constantinople, so that when Dr. Mordtmann returned from Germany, where he had studied medicine in Berlin and Würzburg and had also acted as assistant in the Halle University Medical Clinic, he had an excellent introduction to various classes, both of Turks and foreigners, in the Turkish capital. Both he and his father were eminent linguists and orientalists.—Dr. Oskar Schreyer, railway surgeon to the Shantung line in China. He was murdered by revolutionary soldiers while endeavouring to assist the family of one of the European engineers.—Dr. C. J. van der Burcht van Lichtenberg, formerly inspecting medical officer of the Dutch army.—Dr. Triaire, of Tours, corresponding member of the Paris Academy of Medicine.—Dr. A. Stopezanski, formerly professor of chemistry in the University of Cracow.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council of the Royal College of Surgeons of England, held on March 14th, the under-mentioned diplomas were conferred upon the following gentlemen who have now complied with the by-laws of the College:—

Diploma of Fellow.—Robert Coltart Harkness, M.B., Ch.B. Edinburgh, L.R.C.P., M.R.C.S., Edinburgh and Manchester Universities and St. Bartholomew's Hospital.

Diploma of Member.—John Walter Barron Hanington, M.D. McGill, McGill University and London Hospital.

Licence in Dental Surgery.—Walter Stanley Hoare, Middlesex and National Dental Hospitals; George Matthews, Guy's Hospital; William Macqueen Potter, Charing Cross and Royal Dental Hospitals; and Sidney Thomas Taylor, Middlesex and National Dental Hospitals.

UNIVERSITY OF BRISTOL.—At the second examination for the degrees of M.B., Ch.B., held in March, the following candidates passed:—

Alan Gabriel Bodman, John Wesley Gilbert, William Kenneth Armstrong Richards, Douglas George Clutsam Tasker, and Edward Scott White.

N.B.—This list is issued subject to its approval by Council.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Dr. Mathias Makkas has been recognised as *privat-docent* of Surgery.—*Catania:* Dr. Francesco Caruso has been promoted to the chair of Obstetrics.—*Genoa:* Dr. Luigi Massini has been recognised as *privat-docent* of Internal Pathology.—*Giessen:* Dr. Erich Opitz, of Düsseldorf, has been offered the Professorship of Midwifery and Gynæcology, in succession to Dr. von Franqué, who goes to Bonn.—*Kazan:* Dr. V. Boldyreff, of St. Petersburg, has been appointed to the chair of Pharmacology.—*Leipsic:* A new clinic for diseases of the ear, nose, and throat has been opened. Dr. Paul Frangenheim, formerly of Königsberg, has been recognised as *privat-docent* of Surgery.—*Lima:* The Medical School has recently been celebrating its centenary, as the first buildings were finished and opened during the latter part of 1811. Previously, however, there had been a professor of anatomy, Dr. Don Hypolito Unanue, and it was largely through his exertions that the school was founded.—*Lyons:* Dr. Lesieur, *agrégé*, has been appointed Professor of General Pathology and Therapeutics in succession to Dr. Courmont.—*Padua:* Dr. Carlo Mariani has been recognised as *privat-docent* of Operative Medicine.—*Prague (Bohemian University):* Dr. Josef Novotny has been recognised as *privat-docent* of Hygiene.—*Toulouse:* Dr. Soulié, *agrégé*, has been promoted to the chair of Anatomy in succession to the late Dr. Charpy.—*Tübingen:* Dr. Hans Kolaczek has been recognised as *privat-docent* of Surgery. Dr. Schlayer, *privat-docent* of Medicine, has been promoted to be Extraordinary Professor.—*Würzburg:* Dr. J. Sobotta has been appointed Extraordinary Professor of Topographical Anatomy.

PRINCESS ALICE MEMORIAL HOSPITAL, EASTBOURNE.—The Duke of Devonshire on Saturday evening, March 16th, presided at a complimentary dinner at Eastbourne given to the medical staff of the Princess Alice Memorial Hospital, all the original members of which are now on the retired list, "to show the governors' and their friends' appreciation of the noble and self-sacrificing work which these gentlemen have done for so many years, not only for the healing or relief of the sick poor in the hospital, but also, as an indirect result, for raising of the standard of health, and of medical and surgical efficiency, throughout the whole community." The toast of "The Original Members of the Medical Staff of the Princess Alice Memorial Hospital" was expressively submitted by the chairman and replied to by Dr. H. Colgate and Mr. H. D. Farnell.

THE University of London has received during the week an anonymous contribution of £100,000 towards the acquisition of a site on the Bedford Estate, and an offer of £60,000 to erect upon an approved site a Senate House and administrative offices.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE (LONDON, 1913).—By a mistake the name of Professor Henri Hervieux, M.D., Laval University, Montreal, was omitted from our published list last week of the Canadian nominations to the council of the Section of Therapeutics of this Congress.

LITERARY INTELLIGENCE.—Mr. Heinemann draws attention to the fact that "Microbes and Toxins," by Dr. Etienne Burnet, of the Pasteur Institute, Paris, originally announced at the price of 6*s.* net, will be published at 5*s.* net. Professor Metchnikoff contributes an introduction to the book, which was published last week.

HUNTERIAN SOCIETY.—On Wednesday, March 27th, at 9 P.M., at the London Institution, Finsbury Circus, E.C., the annual discussion will be held, the subject being the Therapeutic Value of Alcohol. The debate will be introduced by Sir Victor Horsley, who will be followed by, among others, Dr. Fred. J. Smith, Professor A. R. Cushny, Mr. M. Cursham Corner, and Dr. J. Langton Hewer. Lantern-slide illustrations will be furnished, and all members of the medical profession are invited.

CHELSEA HOSPITAL FOR WOMEN.—At the forty-first annual general meeting of the governors of this charity, to be held at the hospital on Tuesday, March 26th, at 4 P.M., to receive the annual report, and to transact the ordinary business of an annual meeting, the important matter of the rebuilding of the hospital has been placed upon the agenda. The urgent reasons which have led the council to recommend this step and the King Edward's Hospital Fund to approve it will be submitted, and Lord Castlereagh, M.P., the president of the hospital, will supplement the statement.

NATIONAL INSURANCE ACT.—We understand that the following nominations have been made by the British Medical Association for election to the Advisory Committee under the Insurance Act: Dr. R. M. Beaton (London), Mr. E. B. Turner (London), Dr. T. M. Carter (Bristol), Dr. S. Hodgson (Salford), Dr. J. A. Macdonald (Taunton), Mr. J. Neal (Birmingham), Mr. D. F. Todd (Sunderland), Mr. T. Jenner Verrall (Bath), Dr. A. H. Williams (Harrow), Dr. John Adams (Glasgow), Dr. J. Munro Moir (Inverness), and Dr. E. O. Price.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Nurses' Registration Bill.

MR. MUNRO FERGUSON has reintroduced his Nurses' Registration Bill in the House of Commons, where it has been read a first time. The object of the Bill is to regulate the qualifications of trained nurses and to provide for their registration. It is backed by Dr. ADDISON, Mr. PERCY ALDEN, Mr. BRYCE, Mr. DUNCAN MILLAR, Mr. SCOTT-DICKSON, Mr. REMNANT, Sir GEORGE YOUNGER, Viscount WOLMER, Mr. RAMSAY MACDONALD, Mr. FIELD, and Mr. KERR-SMILEY.

The Bill follows the same lines as the measure of last year. It proposes to institute a General Council for the Registration of Nurses in the United Kingdom consisting of 21 persons. Eight of these at least must be registered medical practitioners. One each is to be appointed by the Local Government Boards for England, Scotland, and Ireland. Three are to be chosen by the British Medical Association and one by the Medico-Psychological Association. The medical superintendents of the fever hospitals which may be recognised as training schools for nurses in fever nursing under the measure are given the right to erect a medical man as their representative. Three members are to be nominated by the Privy Council. Eight representatives are accorded to registered women nurses. Registered male nurses may elect either a medical man or one of themselves, and registered mental nurses are also given a representative. A provisional council is set up by the Bill for the purpose of bringing the measure into operation.

After providing for the setting up of a Register of nurses, the Bill proceeds to define the duties and powers of the Council. Clause 10, which deals at length with this matter, is in the following terms:—

"Subject to the provisions of this Act the duties and powers of the Council shall be as follows: (1) To frame rules—(*a*) regulating their own proceedings; (*b*) regulating the issue of certificates of registration and the conditions of admission to the register of nurses; (*c*) regulating and supervising the course of training and the conduct of examinations and the remuneration of the examiners; (*d*) regulating the admission to the register of persons already in practice as trained nurses *at the commencement of this Act*; (*e*) regulating and supervising and restricting within due limits the practice of registered nurses; (*f*) defining the particulars required to be given in any notice under this Act: (2) to appoint examiners and inspectors: (3) to decide upon the places where and the times when the examinations shall be held: (4) to issue and cancel certificates of registration: (5) to publish annually a register of nurses containing the names, addresses, and qualifications of nurses who have been duly registered under this Act: (6) to decide upon the suspension or removal from the register of the name of any nurse for any breach of the rules and regulations from time to time laid down under this Act by the Council, or for conduct disgraceful in a professional respect, and also to decide upon the restoration to the register of the name of any nurse so suspended or removed: (7) to take proceedings against persons guilty of offences under this Act; and generally to do anything necessary for the due and proper carrying out the provisions of this Act. No rules made under this section shall have effect until the same shall have been approved by the Privy Council, and the Privy Council may approve the rules either without or subject to such modifications as the Privy Council think proper."

Existing nurses may obtain admission to the Nurses Register on the production of satisfactory evidence of training, coupled with three years' experience of nursing. After three years only persons who comply with the requirements of Clause 12 are to be registered. That clause is as follows:—

"At the expiration of the said term of three years any person who claims to be registered under this Act shall be entitled to be so registered, provided that such person has had not less than three years' training under a definite curriculum prescribed by the Council in the wards of a hospital or of hospitals approved of by the Council, or in an institution or institutions which the Local Government Board recommend and certify to be wholly or partly maintained out of rates, or has been trained as a nurse under regulations authorised by the Lords Commissioners of the Admiralty for the sick berth staff of the Royal Navy, or as a nurse under regulations authorised by the Army Council for soldiers of the Royal Army Medical Corps for such term as may be fixed by the Council, and that such person has passed such examination as the Council may prescribe."

The Nurses Register, according to Clause 15, will comprise (1) a general register of women nurses; (2) a supplementary register of male nurses; and (3) a supplementary register of asylum-trained nurses.

The name and description of "Registered Nurse" is specifically appropriated by the Bill to persons actually on the Nursing Register. Persons wrongfully holding themselves out as registered nurses are made liable to a fine not exceeding £10.

A clause has been inserted in the Bill laying down in precise terms that nothing contained in it shall be considered as conferring any authority to practise medicine or to undertake the treatment or cure of disease.

Feeble-minded Persons (Control) Bill.

MR. STEWART'S Bill to provide for the better care and protection of feeble-minded persons has been printed. It is an indication that the mind of Members of Parliament of all parties is being directed to this important subject.

The scheme of Mr. STEWART'S proposals is to vest in the Commissioners in Lunacy the power to license any "home, residential school, institution, colony, or house" for the purpose of the detention of persons certified as feeble-minded under the provisions of the Bill. Clause 8, which in some respects is the most important in the Bill, deals at length with the procedure for the removal of the feeble minded to these licensed institutions. Its terms are as follows:—

"Any stipendiary magistrate or justice of the peace may, upon application being made to him, order the removal of the feeble-minded person in respect of whom such application is made to any home, residential school, institution, colony, or house licensed or registered under this Act and named by the person making the application, provided always that the stipendiary magistrate or justice of the peace is himself satisfied that such feeble-minded person has attained the age of 16 years and is in need of further protection, care, and control, and is a source of injury and mischief to himself or others, and provided that the feeble-minded person in respect of whom application is made has been independently examined by two registered medical practitioners, who shall furnish certificates in writing in the form set out in the First Schedule of this Act to the stipendiary magistrate or justice of the peace to whom application is made." For the purposes of this section application may be made by the following persons, who shall give their information upon oath:—(1) The parent, guardian, or any relative, who has attained the age of 1 years, of the alleged feeble-minded person; (2) the relieving officer or overseer of the parish to which the alleged feeble-minded person shall have become chargeable; (3) any responsible person above the age of 21 years: Provided always that any stipendiary magistrate or justice of the peace, in respect of any case coming before him in his judicial capacity, although no application has been made under

this Act, or otherwise, may call to his aid two registered medical practitioners, and issue an order in accordance with the provisions of this Act for the detention of the feeble-minded person who has been brought before him, provided that the medical practitioners shall have furnished certificates in writing as set out in the First Schedule of this Act, and the stipendiary magistrate or justice of the peace may remand such feeble-minded person certified under this Act to any workhouse or home pending his or her removal to a home, residential school, institution, colony, or house licensed or registered under this Act. Any application made under this section shall be considered in private, and no one, except the applicant, the alleged feeble-minded person and his representative, and the persons signing the medical certificates accompanying the application shall, without the leave of the judicial authority, be present at the consideration thereof. The relieving officer of any parish shall apply to the stipendiary magistrate or justice of the peace for an order to be granted in respect of any person found wandering in that parish, and without care and control, if he is satisfied that such person is a fit and proper person for detention under this Act."

By Clause 9 no feeble-minded person above the age of 16 who has been so certified by two medical practitioners shall be received or detained in a licensed institution unless upon a magistrate's order. No feeble-minded person who has attained the age of 21 years shall be detained for a period exceeding 18 months from the date upon which he has attained such age unless on the written authorisation of the Commissioners in Lunacy. These Commissioners have also wide powers of inspection, visitation, and control. The rights of parents, guardians, and relatives to take charge of feeble-minded persons are maintained.

The form of the medical certificate referred to in Clause 8 is set out in the First Schedule. It reads as follows:—

"I, *A. B.*, a person registered under the Medical Act, 1858, and in the actual practice of the medical profession, do hereby certify that I have carefully examined [*name*] of [*state address*] , and am of opinion that the said [*name*] is feeble-minded, and requires detention as provided for by the Feeble-minded Control Act, 1912, for his own benefit or for the benefit of the public at large.

"I further certify that I have formed this opinion on the following grounds:—(*a*) Evidence of feeble-mindedness. (*b*) Evidence of the absence of proper care and control. (*c*) Evidence as to being a source of injury and mischief to himself or others.

"*Note.*—This may consist either of facts observed by the medical practitioner or of facts supplied by others. When the information is supplied by others it is to be so stated, together with the names and addresses of persons supplying the information.

Signed .....
Address.....
Date ....."

It should be noted that the measure is a private Member's Bill, and is one for which the Government take no responsibility.

Medical Inspection of Schools.

In the report of the Board of Education for the year 1910–11, which has just been presented to Parliament, attention is drawn to the medical inspection of schools. It is stated that the chief medical officer of the Board has dealt in a separate report with the subject as it affects elementary schools. Some comments on the matter as it relates to secondary schools are contained in the Blue-book now issued. It appears from it that systematic provision for medical inspection has been instituted in a considerable number of secondary schools. "From the reports of school medical officers, some of which are regularly printed and issued," the report proceeds, "a large body of material is being collected which will form the basis for a general review of the work, and which will be fertile both in information and in suggestion. On the whole, it appears that systems of medical inspection are based on a similar plan, but with considerable divergence in detail. The inspection is in some cases compulsory, in others optional, and it takes one or more of the following forms: (*a*) inspection on admission, (*b*) periodic inspection during school life, and (*c*) special inspection of cases calling for particular attention. Various methods are in use with regard to the keeping of records, communication with parents, and the connexion with the medical inspection of the arrangements for physical exercises, whether ordinary or remedial. It is needless to discuss the advantages of systematic medical inspection of school children. It may be specially noted that, as regards secondary schools, such inspection is largely the continuation of care for children's health after they leave the elementary schools, for the majority of them are the same children. On Jan. 31st, 1911, 88,256 boys and girls in the grant-earning secondary schools in England, or a little over 60 per cent. of the whole number of pupils in attendance, were ex-public elementary school children. Out of the 862 secondary schools in England on the grant list on Jan. 31st, 1911, there were 581 in which this proportion was over 50 per cent., and in 237 of these it was over 75 per cent. It is wasteful that the benefit of systematic medical inspection should be withdrawn from children merely because they have passed from one kind of public school into another. And the importance of this consideration is greatly enhanced by the fact that the transference takes place when the children are approaching a critical stage in their physical development—a stage in which the risk of over-pressure tends to increase, and in which continuity of treatment is more than ever necessary if the benefit of previous care is not to be largely thrown away."

HOUSE OF COMMONS.

WEDNESDAY, MARCH 13TH.

Sleeping Sickness in Nyasaland.

Dr. CHAPPLE asked the Secretary of State for the Colonies whether he could state how many deaths had taken place from sleeping sickness, how many deaths from trypanosomiasis in domestic animals, and how many trade routes been closed in Nyasaland since the Colonial Office was first advised to relax the big game laws in the interest of humanity and commerce; and whether, if he was not yet satisfied with the evidence that game was a reservoir and Glossina morsitans a carrier of the germ of the disease, he would induce the big game hunters to submit to a temporary sacrifice by yielding to a relaxation of the game laws in the interest of human life and British trade by the promise that the restrictive laws would be reimposed if game and tsetse were proved to be innocent.—Mr. L. HARCOURT replied: The total number of cases of sleeping sickness recorded in Nyasaland up to the end of 1911 was 57, of which 21 are known to have died. I am not in possession of any statistics to show how many domestic animals had died from trypanosomiasis and I am not aware that any trade routes have been closed. My honourable friend assumes that a relaxation of the big game laws is in the interest of humanity and commerce—that is to say, that the presence of the large wild animals and of these alone is prejudicial to human life and to trade, presumably by their bringing the tsetse-fly with them. But it has not been shown that if these animals were to disappear the fly would disappear also, and in any case many animals would remain on which the fly could feed. In the island of Principe, where the fly abounds, there is no big game. The Governor of Nyasaland is in communication with Sir David Bruce, who is at work in his laboratory in the sleeping sickness area in the Protectorate, and I have instructed him to furnish me with definite recommendations as to preventive measures of any kind as soon as Sir David Bruce is in a position to make them. I shall not hesitate to take any steps, however drastic, so soon as the necessity is proved.

Mr. MITCHELL-THOMSON: May I ask the right honourable gentleman whether it will be possible to lay papers on the subject on the table of the House?—Mr. L. HARCOURT: Yes, sir.

The Plague in India.

Mr. CHANCELLOR asked the Under Secretary of State for India whether he would give the latest returns concerning the plague in India, the district most affected, and whether the death-rate, compared with the corresponding period of the previous year, was declining.—Mr. H. LEWIS (on behalf of Mr. MONTAGU): The latest return of plague mortality is for the month of January, 1912. The deaths were 49,229, against 91,434 in January, 1911. The areas most affected are the United Provinces of Agra and Oudh, the Hyderabad State, and the Bombay Presidency. As far as can be judged at present the disease is less virulent than in the preceding year, but there are still two months before the period of maximum intensity will be reached.

Education (Provision of Meals) Bill.

Mr. JOWETT, in moving for leave to introduce his Education (Provision of Meals) Act Amendment Bill, stated that its object was to empower the education authority to continue the school meals throughout holidays and even on Sundays. He said that the report of Sir George Newman, chief medical officer of the Education Department, was in itself quite a sufficient reason for the passing of this Bill. Sir George Newman in his report mentioned various experiments that had been carried out by the local authorities, which showed the need for the feeding of school children being continued during the holidays. Amongst the experiments was one carried out by Dr. Ralph Crowley, of Bradford, whose experiments showed that during the time the children were on holiday, instead of receiving benefit, they became actually physically less fit because they were not having the school meals.

Leave having been granted, the Bill was brought in and read a first time.

Insanity in Ireland.

Mr. GINNELL asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state the number of the persons during the last five years in Ireland certified by medical practitioners as insane who were released as sane within 12 months; the total cost to asylums in respect of those persons; whether he was aware that a rule of the Local Government Board allowed no fee to be paid to the examiner unless he gave a certificate of insanity; and whether, in the interest of ratepayers, he would have that rule altered and a fee paid for the examination, irrespective of its result.—Mr. BIRRELL wrote in reply: It is presumed that the honourable Member's question refers to the district and auxiliary asylums. The number of persons during the five years 1906–10, the latest date for which information is available, in Ireland certified by medical practitioners as insane who were released as sane (recovered) within 12 months was 5506. The cost to asylums in respect of these persons cannot be given, as the record of their cost is not kept distinct from that of the other patients. The Local Government Board has made no rule such as that suggested in the question. The majority of admissions to Irish public asylums are effected under the tenth section of the Act 30 & 31 Vic. Cap. 118. The payment of such fee in such cases is regulated by the fourteenth section of the Act 38 & 39 Vic. Cap. 67, which leaves the matter at the discretion of the committing magistrates.

THURSDAY, MARCH 14TH.

Medical Referees in Scotland.

Mr. WATT asked the Secretary of State for the Home Department to state how many medical men had been appointed in Scotland, under the Workmen's Compensation Acts, to sit as assessors along with sheriffs and sheriffs-substitute in dealing with cases under these Acts; whether it was a condition of their appointments that they shall not act in similar cases as expert medical witnesses; and, if not, would he make it a condition in future appointments.—Mr. MCKENNA said in reply: There are 84 medical referees appointed under the Workmen's Compensation Act for Scotland, and in 1910 they sat as assessors on 192 occasions. The Act prohibits a referee from acting in any case in which

he has been employed as medical practitioner, and the Home Office regulations forbid medical referees as a general rule acting privately in any case in which the workman is receiving a weekly payment for compensation or which is otherwise likely to come before a referee in the district for which he acts. I believe that these instructions are usually observed. It has not been found practicable to impose any further restriction on the medical referees.

The Insurance Act.

Mr. ORMSBY-GORE asked the Secretary to the Treasury, whether the National Insurance Commission (Wales) had taken any steps to secure the establishment of provisional local health committees in the Welsh counties and county boroughs, in view of the number of points which must be decided by the local health committees the moment the Act came into force in four months' time.—Mr. MASTERMAN answered: The steps required to secure the establishment of local insurance committees in Wales are under the consideration of the Welsh Commissioners.

Viscount WOLMER asked the Secretary to the Treasury whether, in view of the fact that small Friendly Societies in the country were finding considerable difficulty in accommodating their constitution and management to the conditions of the National Insurance Act, the Insurance Commissioners would arrange that the Act should not come into force until the last possible date, that is, Jan. 1st, 1913.—Mr. MASTERMAN replied: The answer is in the negative. The Commissioners are offering every assistance to all societies by the supply of information through lectures, by the issue of model rules and other literature, and by correspondence and interviews in their office. There is no doubt that it is in the interest of all classes of the community, and especially members of existing Friendly Societies, that the Act should come into operation at the earliest possible moment—i.e., on July 15th, 1912.

The Marquis of TULLIBARDINE asked the Secretary to the Treasury whether any part of the contribution payable by the workman, the employer, or the State under the National Insurance Act was available for the provision of sanatorium benefit for the wives and children of insured persons; and, if not, how was such treatment to be provided.—Mr. MASTERMAN answered: Under section 17 (1) insurance committees may extend sanatorium benefit to the dependents of insured persons. In such cases the cost of their treatment may be met from the general funds available for sanatorium benefit. These include the sums specified in section 16 (2) (*a*) which are contributed jointly by employers, employees, and the State, the sums specified in section 16 (2) (*b*) which are contributed by the State, and any further sums which may be provided under section 17 in equal moieties by the State and local authorities.

MONDAY, MARCH 18TH.

Blackpool Small-pox Hospital.

Mr. SUTTON asked the President of the Local Government Board whether he had been asked to sanction the conversion of the small-pox hospital maintained by the borough of Blackpool and the districts of Fylde, Preston, and Garstang into a sanatorium for tuberculous patients on the ground that it had never once been used since its erection ten years ago; if so, whether he had given the consent requested; and whether the result of the neglect of vaccination, through the Vaccination Acts of 1898 and 1907, had been to make small-pox liability less than had ever before been known in Great Britain.—Mr. BURNS replied: With regard to the first part of the question I received an application from the joint board, who maintain the hospital referred, to for an order to empower them to treat cases of pulmonary tuberculosis at the hospital, and a local inquiry was held in regard to it. The inspector who visited the site of the hospital reports that it is not suitable for the treatment of pulmonary tuberculosis, and I have informed the joint board that I do not propose to make any order in the matter. With regard to the second part of the question I prefer to express no opinion.

Testing Milk for Tuberculosis.

Mr. MOUNT asked the President of the Local Government Board whether he was aware that samples of milk for the purpose of testing for tuberculosis had been of late taken from churns arriving in London without first mixing the milk; and whether, in view of the fact that this abstraction of the cream would prejudically affect the milk if it were afterwards tested for fat, he would give instructions that no samples should be taken in future unless the milk was properly mixed.—Mr. BURNS answered: I am advised that the method of taking the samples is such that the percentage of fat in the milk is not likely to be altered to any material extent.

Preservatives in Milk.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether he proposed in the Board's regulations for the restriction of the use of preservatives in milk and cream to prohibit the use of formalin as a preservative of cream, but to permit the use for that purpose of boric acid, biborate of soda, and other like antiseptics deemed by medical experts to have an injurious effect upon the nervous system; whether, and for what reason, his expert advisers differentiated between these various adulterants; and whether sterilisation and keeping under suitable atmospheric conditions would in their opinion render unnecessary the use of all such preservatives.—Mr. BURNS said in reply: The draft regulations which I have had prepared propose to prohibit the use of formalin in cream, but not to prohibit the use of boric acid, borax, or a mixture of those preservative substances, provided that a full declaration of the presence of the preservative and the amount added is made in the manner prescribed by the regulations. The considerations which have been taken into account in framing the draft regulations in question are dealt with in Dr. Hamill's report to the Local Government Board respecting the use of preservatives in cream.

The Adulteration of Flour.

Sir JOHN LONSDALE asked the President of the Local Government Board whether his attention had been called to the fact that materials for the adulteration of flour were being advertised and used by millers throughout the country; and whether, having regard to the fact that the introduction of many of these substances into flour was prejudicial to the public health, he would give an undertaking to introduce immediately legislation for the purpose of putting a stop to this practice.—Mr. BURNS answered: Section 3 of the Sale of Food and Drugs Act, 1875, provides that no person shall mix any article of food with any ingredient or material so as to render the article injurious to health with intent that the same may be sold in that state The penalty for a first offence against this enactment is a fine not exceeding £50, and for a subsequent offence imprisonment not exceeding six months. This section seems to me to deal with practices such as are described in the honourable baronet's question.

WEDNESDAY, MARCH 20TH.

Medical Men and the Insurance Act.

Sir PHILIP MAGNUS asked the Secretary to the Treasury whether he could state the present position of the negotiations between the Insurance Commissioners and the representatives of the medical profession; whether any reply had been sent to their letter of Feb. 29th embodying the conditions under which they were prepared to coöperate in the working of the Act; and whether the Commissioners would issue such regulations as would enable them to give effect to the requirements of the medical profession as set forth in their letter.

Mr. FELL had also on the notice paper a question to the honourable gentleman asking whether any progress had been made in the negotiations with the doctors as to their working under the National Insurance Act; and if the six points which they had asked would be agreed to by the Insurance Commissioners.

Mr. MASTERMAN said in reply: I propose to answer both these questions together. The British Medical Association have availed themselves of the opportunity afforded them by the Commissioners to recommend practitioners experienced in general practice for appointment as members of the Advisory Committee, and the gentlemen so recommended will be appointed on that committee. The letter of Feb. 29th has been acknowledged. No regulations have, however, yet been considered by the Joint Committee on this matter, as they recognise that this is essentially a subject in which the advice and assistance of the Advisory Committee is desirable.

Sir PHILIP MAGNUS asked the honourable gentleman whether in the event of the Insurance Committees or the Insurance Commissioners being unable to satisfy the requirements of the medical profession, and consequently deciding to adopt the alternative proposal of the Act—viz., to suspend medical benefit and to return to the insured person the money equivalent to such benefit—the insured person would be free to use that money for any purpose he might think fit; and, if so, whether the insured person would necessarily receive under the Act any medical benefit whatever.—Mr. MASTERMAN replied: If the normal scheme of medical benefit laid down in Section 15 is not carried out, not one, but several alternatives are provided by the Act. These include power for the Commissioners themselves to authorise the Local Insurance Committees to make other arrangements for providing medical benefit, or for themselves making such arrangements as they think fit, or for suspending medical benefit for any period and paying to each insured person an equivalent sum. Even if the last course were adopted the insured person would be free, though not compelled, to make his own arrangements for medical treatment.

Mr. FELL asked the honourable gentleman whether the appointments that were being made under the National Insurance Act were being made provisionally and were subject to determination if no agreement was come to with the doctors who were to work the Act.—Mr. MASTERMAN said in reply: The answer is in the negative. The coming into operation of the Act is not dependent upon any agreement that may be made with representatives of the medical profession.

Mr. FELL: What is the use of bringing it into operation if those who are supposed to carry it out refuse to do so?—Mr. MASTERMAN: I do not understand the question. If necessary, the Act will be worked without medical benefits as in Ireland.

BOOKS, ETC., RECEIVED.

AFRICAN WORLD, THE, LIMITED, 1, Gresham Buildings, Basinghall-street, London, E.C.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Wolston, in the county of Warwick; and at Conway, in the county of Carnarvon.

Births, Marriages, and Deaths.

BIRTHS.

THOMAS.—On March 15th, at Colston-parade, Redcliffe, Bristol, the wife of J. M. M. Thomas, M.R.C.S., L.R.C.P., of a son.
YOUNG.—On March 13th, at Stoney Stanton, Leicestershire, the wife of Graham Pallister Young, M.B., B.S. Lond., M.R.C.S., L.R.C.P., of a daughter.

DEATHS.

CLARKE.—On March 11th, at Rockleigh, Whiteladies-road, Clifton, Bristol, William Thomas Clarke, M.R.C.S., L.R.C.P., eldest son of T. W. Clarke.
RYMER.—On Jan. 11th, at Fort Resolution, Great Slave Lake, N.W.T., Canada, James Francis Rymer, M.R.C.S., L.D.S., D.D.S., aged 48 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

INCOME-TAX AND THE MEDICAL PROFESSION.

A CORRESPONDENT writes:—"I should be very much obliged for information on the following point regarding income-tax. In calculating the net income for taxation, is it permitted to deduct from the gross receipts of a practice fees paid to a locum tenens? My partner and I furnish the surveyor of taxes, at his request, with a statement at the beginning of each year of our gross income and a detailed account of our practice expenses. In former years we have always been allowed to include locum fees in practice expenses. This year the surveyor informs us that we cannot do so, and quotes a recent legal judgment to show he is right. I enclose a copy of his letter." The surveyor in his letter says: "The locum fees have been added back because they are not considered as being necessary expenses. There is no provision for the allowance of any sum paid to another man to do part of the work of the profession—in fact, it was decided in the case of Lothian *v.* Macrae that should such allowances be claimed they were not admissible as income-tax deductions." We do not know the circumstances of the case referred to by the surveyor, but our opinion is that our correspondent is justified in deducting the cost of an assistant or locum-tenent; we consider that he should appeal to the Commissioners if the surveyor insists on his view. Such deductions have always been allowed in the past, and this particular deduction was given in the model form of return published in THE LANCET of July 4th, 1896 (now out of print), which was based on an actual return produced to the Commissioners and allowed by them. We do not know what distinction (if any) is here attempted to be drawn between an "assistant" and a "locum-tenent"; but to say that the fees of the latter "are not considered as being necessary expenses" appear to suggest that a medical man may not deduct his assistant's salary.

To the Editor of THE LANCET.

SIR,—Claims for repayment of income-tax for the year ended April 5th, 1909, must be lodged before April 5th next (Good Friday), otherwise the right to claim for that year will be lost, as the Inland Revenue authorities will not extend the time under any circumstances.

Yours faithfully,

THE INCOME-TAX ADJUSTMENT AGENCY, LIMITED,
E. MONTAGUE, Secretary.

9, 10, and 11, Poultry, Cheapside, E.C., March 20th, 1912.

AN INTERESTING FACT.

To the Editor of THE LANCET.

SIR,—On Sept. 13th, 1882, I removed an ovarian cyst from a woman aged 61. The case was reported in THE LANCET, Feb. 17th, 1883. It may interest your readers to know that the patient celebrated her ninetieth birthday on Nov. 4th, 1911, and is still alive and in possession of all her faculties. The case is uncommon and may be worth recording.

I am, Sir, yours faithfully,

A. C. BUTLER-SMYTHE, F.R.C.S. Edin.

Brook-street, W., March 12th, 1912.

DOMESTIC ECONOMY FOR HOUSEWIVES.

THE Woman's Industrial Council, of 7, John-street Adelphi, W.C., is issuing a series of penny handbooks (by post 1½*d.*) in illustration of domestic difficulties. We have before us five such pamphlets by Marguerite Fedden, which should prove eminently useful to those who really desire to acquire training in methodical house work, and it is only by method that good results can be looked for. "How to Cook a Simple Meal" gives some preliminary instruction on the underlying principles of cooking, followed by detailed accounts how to proceed step by step in preparing all kinds of dishes. "How to Clean a House" is equally precise and orderly in its directions. The same remarks apply to "How to do the Weekly Mending," "How to do the Weekly Wash," and "How to do your own Upholstery and Machining."

If to these be added the "Home Handbook, Health and Hygiene" (London: The Incorporated Institute of Hygiene. Pp. 82. Price 3*d.*), which expounds the basic principles of health and hygiene in relation to diet, clothing, personal hygiene, the rearing of children, nursing, sanitation of the house, nursery, and bedroom, disposal of refuse, and prevention of fire, even the poorest will possess a library of useful information on domestic economy that, if properly studied, will enable them to become proficient in household management.

"606" IN BILHARZIOSIS.

To the Editor of THE LANCET.

SIR,—I should be glad if any of your Cairo correspondents would kindly say what benefit, if any, has been derived from the venous injection of "606" in cases of bilharziosis.

I am, Sir, yours faithfully,

"PERPLEXED."

THE CAUSES OF A MEDICAL PRACTITIONER'S BANKRUPTCY.

Mr. A. C. B. Jones, a medical man practising at Chatham, presented himself recently for public examination as a bankrupt at the court at Rochester, and in explaining the causes of his insolvency made the following statement: His assets stated on paper showed a surplus over his liabilities of £60, but this was on the assumption that the value of his practice was correctly represented at the sum of £400. He was of the opinion that at that figure it could have been disposed of but for the intervention of the National Insurance Act, the introduction of which in Parliament and its passing had rendered the sale of practices of this class a matter of extreme difficulty. He had been informed by the agent to whom he had entrusted it that the effect of the Act had been such as practically to put an end to sales, so that he had not sold one for a year. A further cause of the debtor's position was to be found in the Midwives Act, which had diminished his former income by £150 per annum. According to his experience many ladies preferred employing midwives to medical men since the status of the midwife had been raised. Mr. Jones was allowed to pass his examination. His story is not one to encourage those who contemplate entering the medical profession, and it is for the serious consideration of legislators that in this concrete instance serious financial loss to a medical practitioner should be directly traceable to the effect of two benevolently intended Acts of Parliament. That Parliament should legislate in the interest of the public health is as it should be, but the public health is in the custody of the medical profession, and it can be of no benefit to the public so to lower the possible emoluments of everyday professional practice that young men of good ability are driven to enter upon other pursuits, leaving their intellectual inferiors to fill places which should be theirs.

VENERABLE VERITIES.

To the Editor of THE LANCET.

SIR,—Some time ago there was some controversy in the medical press as to certain well-known verses, of Hudibrasian flavour, which, writing only from my memory of them, were:—

The devil was sick, the devil a saint would be;
The devil was well, the devil a saint was he.

And—

When we are ill, but not before,
God and the doctor we adore.
When we get well, both are requited;
God is forgotten, the doctor "slighted."

Is it well known that the idea of these verses—so true, alas! to our edical experience—may be found in Rabelais, who gives in his "Pantagruel," as a "proverbe lombardique," the Italian verse:—

Passato el pericolo, gabbato el santo.
(Le danger passé, est le saint moqué.)

I am, Sir, yours faithfully,

Birmingham, March 1st, 1912. JAMES SAWYER.

"*Rus*" inquires: What is the best method of treating the papered walls of rooms in which illness or deaths have occurred in such cases as death from bronchitis, cancer, or a disease not usually attributed to a micro-organism? Must sulphur or formalin be used? Or is there any dry method or wet method by spraying or washing of the paper which can be used, whereby the paper of the walls can be allowed to remain and by which no repapering will probably be rendered necessary?

*** The usual procedure recommended by health officials and sanitary officers is that the room should be emptied of all furniture, that this and the room should be thoroughly scrubbed, and that the walls should be rubbed down with dough and sprayed with formalin.—ED.L.

W. B. F.—In a hospital which possesses two resident medical officers and a resident dispenser it is neither customary nor desirable that the matron or any other unqualified person should have charge of the dispensary keys.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1912:—

March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
" 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
" 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.
" 9th–11th (Paris).—Congress of Physiotherapy for French-speaking Physicians.
April 9th (Berlin).—Eleventh Congress of the German Society for Orthopædic Surgery.
" 9th–13th (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
" 10th–13th (Berlin).—Forty-first Congress of the German Surgical Society.
" 12th–30th (London, Olympia).—Ideal Homes Exhibition.
" 14th (Berlin).—Eighth Congress of the German Röntgen Society.
" 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
" 15th–18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
" 21st–24th (Munich).—Twenty-sixth Meeting of the Anatomical Society.
May 7th–17th (Washington).—Ninth International Red Cross Conference.
" 13th (London, Guildhall).—Conference on Diet in Schools.
" 23rd (opens) (Philadelphia).—Twelfth International Congress on Navigation.
" 23rd–25th (Hanover).—Nineteenth Meeting of the Union of German Laryngologists.
" 25th–27th (Paris).—International Musical Festival.
" 26th–28th (Paris).—National Conference of the "Gouttes de Lait."
Whitsuntide (Portrush).—British Esperanto Congress
May 27th–June 1st (London).—Eighteenth International Congress of Americanists.
" 29th–31st (Berlin).—Fifteenth Session of the German Society for Gynæcology.
" (London).—International Horticultural Exhibition.
May to October (London, Earl's Court).—Shakespeare's England.
June 11th–14th (Caxton Hall, Westminster).—Second National Conference on the Prevention of Destitution.
" 24th–27th (London).—The (Biennial) Health Conference and Exhibition.
" (London).—Missionary Exhibition.
" (Atlantic City, N.J.).—Annual Meeting of the American Medical Association.
" (Birmingham).—Tuberculosis Exhibition.
" (London, Science Museum, South Kensington).—Second Optical Convention.
July 2nd–5th (London).—Congress of the Universities of the Empire.
" 2nd–6th (Doncaster).—Seventy-third Annual Show of the Royal Agricultural Society of England.
" 4th–6th (Dublin).—Celebration of the Bicentenary of the School of Physic in Ireland (Medical School of Trinity College, Dublin).
" 12th–16th (London).—Imperial Conference of Teachers' Associations.
" 17th–19th (Oxford).—Oxford Ophthalmological Congress.
" 19th–27th (Liverpool).—British Medical Association, Eightieth Annual Meeting.
" 24th–30th (University of London).—First International Eugenic Congress.
" 25th–28th (Berlin).—Royal Institute of Public Health.
" 29th–August 3rd (York).—Congress and Exhibition of the Royal Sanitary Institute.
Aug. 5th–10th (Oxford).—Second International Congress of Entomology.
" 7th–10th (Glasgow University).—Thirty-second Annual Meeting of the British Dental Association.
" 10th–Sept. 6th (Balkans, Turkey, Greece).—Ninth Annual Congress of the Association Internationale de Perfectionnement Scientifique (A.P.M.).
" 12th–17th (Boston, U.S.A.).—Ninth International Otological Congress.
" (end) (Cracow).—International Esperanto Congress.
Sept. 4th (Washington, D.C.) and Sept. 6th–13th (New York).—Eighth International Congress of Applied Chemistry.
" 4th (opens) (Dundee).—British Association.
" 9th–10th (San Sebastian).—Third Spanish Congress of Tuberculosis.
" 10th–12th (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
" 23rd–28th (Washington, D.C.).—Fifteenth International Congress on Hygiene and Demography.
" 27th–29th (Hamburg).—Sixth Annual Meeting of the German Society of Specialists in Nerve Diseases.
" (Prague).—International Congress of Radiology and Medical Electrology.
Oct. 9th–12th (New York).—Electrical Exposition and Automobile Show.
" 13th–16th (Paris).—Thirteenth French Congress of Medicine.
(Budapest).—Tuberculosis Exhibition.
(Stockholm).—Olympic Games.
(Düsseldorf).—Third International Medical Accident Congress.
(Perth, Western Australia).—(Three days.) Health Congress.
(Edmonton).—Annual Meeting of the Canadian Medical Association.

In 1913:—

(Easter week) (Berlin).—Fourth International Congress for Physiotherapy.
Aug. 6th–12th.—(London).—Seventeenth International Congress of Medicine.
" 22nd–28th (Cambridge).—International Mathematical Congress.
(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)
(Chicago).—Congress of the International Association of Refr[illegible] geration.

(Washington).—Congress of American Physicians and Surgeons.
(Paris).—Congress of Physical Education.
(Milan).—Fourteenth International Anti-alcoholic Congress.
(Buffalo).—Fourth International Congress of School Hygiene.

In 1914:—
(Vienna).—Third International Congress for Professional Diseases.
(Auckland, N.Z.).—Australasian Medical Congress.
(St. Petersburg).—Third Mendeléeff Congress of Pure and Applied Chemistry and Physics.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Dr. G. J. Burch: A Confusion Test for Colour Blindness.—Mr. C. Dobell: On the Systematic Position of the Spirochætæ (communicated by Prof. A. Sedgwick).—Mr. E. C. Snow: The Influence of Selection and Assortative Mating on the Ancestral and Fraternal Correlations of a Mendelian Population (communicated by Prof. Karl Pearson).—Mr. T. Lewis and Mr. M. D. D. Gilder: The Human Electrocardiogram: a Preliminary Investigation of Young Male Adults to Form a Basis for Pathological Study (communicated by Sir J. R. Bradford, K.C.M.G., secretary of the Royal Society).—Mr. C. Revis: The Production of Variation in the Physiological Activity in B. Coli by the Use of Malachite-green (communicated by Sir J. R. Bradford, K.C.M.G.).—Muriel Robertson: Notes on Some Flagellate Infections Found in Certain Hemiptera in Uganda (communicated by Sir J. R. Bradford, K.C.M.G.).—Muriel Robertson: Notes on Certain Aspects of the Development of T. Gambiensi in Glossina Palpalis (communicated by Sir J. R. Bradford, K.C.M.G.).—Dr. H. L. Duke: Antelopes and their Relation to Trypanosomiasis (communicated by Sir J. R. Bradford, K.C.M.G.).

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

MONDAY.
ODONTOLOGICAL SECTION (Hon. Secretaries—W. W. James, Stanley Mummery): at 8 P.M.
Paper:
Mr. Douglas Gabell: The Position of Swivels on Spring Dentures.
Casual Communications:
Mr. H. B. Dowsett: Case of General Exostosis of all the Maxillary Teeth.
Mr. T. Campbell Dykes: Models showing Variation in Number, Size, and Position of Teeth—Incisors and Canines.

TUESDAY.
MEDICAL SECTION (Hon. Secretaries—Sir John F. H. Broadbent, Bt., Robert Hutchison): at 5.30 P.M.
Papers:
Sir Lauder Brunton, Bt., F.R.S.: Abdominal Angina.
Dr. Hertz: Functional Hour-glass Stomach.

FRIDAY.
LARYNGOLOGICAL SECTION (Hon. Secretaries—W. H. Kelson. Dan McKenzie), at 11, Chandos-street, W.: at 4.30 P.M.
Cases and Specimens
Will be shown by Dr. Peters, Dr. Irwin Moore, Dr. Brown Kelly, Mr. Stuart-Low, Dr. Kelson, Mr. Waggett, Dr. E. D. Davis, and others.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., Clinical Evening. Cases will be exhibited by Dr. P. Weber, Mr. A. E. Barker, Dr. de Havilland Hall, Mr. A. Lane, Mr. Barrington-Ward, Dr. E. Wynter, Mr. H. J. Curtis, Dr. W. Branson, Dr. F. S. Palmer, and others.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—9 P.M., Discussion on the Therapeutic Value of Alcohol, to be opened by Sir Victor Horsley, followed by Dr. F. J. Smith, Prof. A. R. Cushny, Mr. M. C. Corner, Dr. J. L. Hewer, and others. (Lantern slide illustrations.)

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Dr. C. Shaw: The Material Obligations of Spiritualism and Allied Phenomena. (Harveian Lecture.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Dr. E. Fawcett: The Development of the Human Chondro-cranium and Various Cranial Bones.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. W. Fox: Clinique (Skin). 5.15 P.M., Lecture:—Dr. T. D. Lister: Some Clinical Difficulties in Sanatorium Insurance.
TUESDAY.—4 P.M., Dr. J. Parkinson: Clinique (Medical). 5.15 P.M., Dr. J. S. R. Russell: Myelitis and its Treatment (with lantern demonstration).
WEDNESDAY.—4 P.M., Mr. C. Ryall: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. A. E. Giles: Pernicious Effects of Uterine Fibroids.
THURSDAY.—4 P.M., Dr. D. W. Carmalt-Jones: Clinique (Medical). 5.15 P.M., Lecture:—Mr. Clayton-Greene: Some Bacterial Infections of the Urinary Tract.
FRIDAY.—4 P.M., Dr. G. Thompson: Clinique (Eye). 5.15 P.M., Lecture:—Dr. W. Wingrave: Some Points in the Pathology of Sputum.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham): Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).
TUESDAY.—Clinic: 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld.); Surgical (Mr. Howell Evans); Gynæcological (Dr. A. W. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Mr. H. Evans: Varicose Veins and Varicose Ulcers.
WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. W. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir Dyce Duckworth: The Varieties and Significance of Cough.
TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Mr. Gray: Some Points in the Relationship of the Nervous System to the Surgery of the Peritoneum.

LISTER INSTITUTE OF PREVENTIVE MEDICINE, Lecture Theatre of the Lister Institute, Chelsea Bridge-road, S.W.

TUESDAY.—5 P.M., Dr. W. Nicoll: Modern Aspects of Helminthology—Special Features of the Trematode Parasites of Man. (Lecture III.)
FRIDAY.—5 P.M., Dr. W. Nicoll: Modern Aspects of Helminthology—Special Features of the Cestode Parasites of Man. (Lecture IV.)

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

THURSDAY.—3 P.M., Dr. F. A. Dixey: Sexual Dimorphism in Butterflies.
FRIDAY.—9 P.M., Prof. Sir J. J. Thomson: Results of the Application of Positive Rays to the Study of Chemical Problems.
SATURDAY.—3 P.M., Prof. Sir J. J. Thomson: Molecular Physics (Lecture VI.)

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., A Demonstration of Medical and Surgical Cases will be given by Members of the Honorary Staff. (Post-Graduate Clinic.)

MANCHESTER ROYAL INFIRMARY.

TUESDAY.—4.30 P.M., Dr. Murray: The Clinical Significance of Hæmorrhage as an Early Sign of Disease. (Post-Graduate Clinic.)

SALFORD ROYAL HOSPITAL.

THURSDAY.—4.30 P.M., Mr. R. Ollerenshaw: Some Common Deformities and their Treatment. (Post-Graduate Course).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (27th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (28th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (30th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1911 were given in THE LANCET of Dec. 30th, 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

ON

PARATYPHOID FEVER AND MEAT POISONING.

Delivered before the Royal College of Physicians of London

BY F. A. BAINBRIDGE, M.A., M.D. CANTAB., F.R.C.P. LOND., D.P.H.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF DURHAM.

LECTURE III.[1]

Delivered on March 7th.

I.—B. SUIPESTIFER.

MR. PRESIDENT AND GENTLEMEN,—The following account is based on 40 outbreaks of meat poisoning in which B. suipestifer was obtained. In 28 of these the bacillus was obtained from the patients, twice from the blood, eight times from the spleen and other viscera, and in the remainder from the stools. In 21 cases it was obtained from the meat which was regarded as the cause of the outbreak. In 26 cases the serum of the patients gave a positive reaction for the bacillus which was isolated. In all these outbreaks the illness was definitely attributed to the consumption of some particular article of food. According to the evidence the illness was confined to those who ate the sample of meat, although not every one who partook of it was ill.

There are also one or two instances in which acute gastro-enteritis has followed directly on the accidental ingestion by the mouth of strains of so-called B. typhi murium which were probably identical with B. suipestifer. Shibayama described a case in which a family mixed a culture of B. typhi murium with food for the purpose of destroying mice, and subsequently prepared their own supper in the same bowl. On the following day they were all ill with symptoms of acute gastro-enteritis. The bacillus was recovered from their stools and their serum gave a positive reaction for it. Similar cases of infection have been recorded by Mayer and by Trommsdorf.

DISTRIBUTION OF B. SUIPESTIFER.

(*a*) *England.*

The bacillus has been isolated from the patients in at least six outbreaks of meat poisoning in this country; in some of these it was also obtained from the meat which caused the illness. It has also been found by Murray, Williams, and Rundle in seven cases which clinically were summer diarrhœa, and once or twice by Morgan in similar cases.

Apart from these cases, B. suipestifer has rarely, if ever, been met with in man. Nor has it been isolated either from food of various kinds or from the alimentary canal of pigs. (Savage, Bainbridge.) The bacillus is not infrequently obtained, however, from guinea-pigs (Petrie and O'Brien), and is occasionally present in mice (Bainbridge, Savage). In these animals it occurs both in health and as a cause of epizootic disease.

(*b*) *Germany.*

There is a widespread belief among German writers, of whom Hübener is the most prominent, that it has a wide distribution and is commonly present in the alimentary canal of healthy men and animals and also in food which has been subsequently eaten without causing disease. Although these writers describe the bacilli which they find as "paratyphoid" bacilli the examination of some of the strains by the absorption method makes it clear that in many, if not in all, cases they were really dealing with B. suipestifer. It has further been shown by Uhlenhuth and by Seiffert that B. suipestifer can be obtained from the fæces in from 5 to 8 per cent. of healthy pigs. An active controversy has taken place in Germany between the upholders of this view, and those who find the organism almost entirely confined in its distribution to outbreaks of disease. Without going into the details of this controversy it would appear that Hübener's view has been largely discredited.

1. *Man.*—It has been shown, in the first place, that the occurrence of B. suspestifer in healthy men is practically confined to certain areas of Germany and is not universal. Even in those districts in which its presence has been demonstrated the bacilli have been obtained in very scanty numbers from any given person, and often only once from the same individual even after repeated examination of the stools. In several districts in Germany careful and extensive examination of human excreta has failed to demonstrate the presence of the bacillus except in association with meat poisoning. Among such investigations may be mentioned those of Aumann, Sobernheim, and Seiffert. Aumann concludes that the bacillus is not more widely distributed apart from disease than other organisms such as B. typhosus or the diphtheria bacillus whose pathogenic power is undoubted.

2. *Food.*—Secondly, the earlier statement of Mühlens, Dahm, and Fürst as to the frequent presence of B. suipestifer in food has not been confirmed. The authors fed mice on a large number of samples of uncooked meat (chiefly ham and goose), which appeared healthy and were subsequently eaten by men without ill effects. Many of the mice died and B. suipestifer was obtained from their organs, although it could not be isolated directly from the meat. The conclusion was drawn by these writers that B. suipestifer was often present in sound meat and that it had therefore no causal relation to meat poisoning. The fallacious character of these observations was pointed out by Holth and by Zwick and Weichel. They found that the high mortality among the mice was chiefly due to their being fed upon an unaccustomed diet, which caused enteritis. A contributory factor was the partial starvation of the animals owing to their dislike of the food. They also ascertained that B. suipestifer was a common inhabitant of the mouse's alimentary canal, and was frequently present in the tissues of mice whatever the cause of death. Apparently the effect of this strange diet so modified the conditions of the alimentary canal of mice that B. suipestifer was enabled to make its way from the intestine into the general circulation, and there was no evidence that the bacilli were introduced by the food. Aumann has also carried out a very extensive investigation of various foods, including meat, sausages, milk, fish, bread, and vegetables, involving the examination of 707 samples. Only 5 of these yielded bacilli of the suipestifer type, and in all of them the food had given rise to disease in man.

3. *Animals.*—Thirdly, the bulk of evidence goes to show that B. suipestifer is not widely distributed among domestic animals. Two hundred samples of fæces from healthy pigs, cattle, sheep, and calves were examined by Aumann, who did not find it on a single occasion. Müller, Edenhuyzen, Portet, and Sobernheim were all almost equally unsuccessful.

It is probable, therefore, that this organism is not very widely distributed either in this country or in Germany, and that its occurrence, either in man, in food, or in the domestic animals, is infrequent except in association with meat poisoning. An exception to this statement may perhaps be made as regards pigs; although the evidence is not unanimous it undoubtedly occurs from time to time in the pig and is relatively frequent in this as compared with other animals. It is also commonly present in the intestine both of mice and of guinea-pigs.

The evidence as to the distribution of B. suipestifer may be summarised as follows:—1. Its normal habitat is the alimentary canal of mice, guinea-pigs, and of pigs; it is rarely obtained from other domestic animals. 2. In meat poisoning in man it has been frequently isolated from patients and from meat. 3. Apart from such outbreaks, it is rarely obtained either from the human alimentary canal or from food.

THE RELATION OF B. SUIPESTIFER TO MEAT POISONING.

The foregoing facts as to the distribution of B. suipestifer furnish good grounds for regarding it as a cause of meat poisoning. Confirmatory evidence is afforded by the fact that the patients not only excrete the bacillus but elaborate agglutinins for it. While admitting the frequent association of this bacillus with outbreaks of meat poisoning some have supposed, however, that it is not the true cause of the disease, but is merely a secondary invader. The view has been put forward that meat poisoning (like swine fever) is

[1] Lectures I. and II. were published in THE LANCET on March 16th (p. 705) and 23rd (p. 771), 1912, respectively.

caused by a filter passer. But attempts to demonstrate the existence of a filter passer in cases of meat poisoning have been unsuccessful. It is, further, necessary to assume, if this view be correct, that B. suipestifer occurs very often either in the human intestine or in food; and this assumption is not in accordance with the facts.

It may be fairly concluded, therefore, that B. suipestifer causes meat poisoning. This conclusion is not invalidated by the observation that the bacillus may occasionally be ingested in small numbers by man without producing evil effects. This happens in the case of admittedly pathogenic organisms; it is known, for instance, that B. typhosus is occasionally taken into the body and excreted without giving rise to clinical symptoms of disease. Indeed, the capacity of almost every organism to produce an infection must always depend in part upon the number of bacilli entering the body and upon the susceptibility of the individual.

EPIDEMIOLOGY.

One of the most striking features of outbreaks due to B. suipestifer is the frequency with which the meat to which the illness was attributed was derived from the pig. The analysis of 28 outbreaks shows the following to be the sources of the food: pig, 16 cases; cow, 9 cases; horse, 3 cases. In eight cases the animal was ill at the time when it was slaughtered, and in several, probably all, of these cases it was suffering from infection with B. suipestifer. In the other outbreaks there is no evidence that the animals whose flesh was eaten were diseased, and in several instances they are stated to have been perfectly healthy when slaughtered.

Meat may become infected with this bacillus in one of two ways. On the one hand, the organisms may reach the tissues and the muscles during life as a result of a septicæmia. The outbreak at Aertrycke, for example, followed the consumption of meat from a sick calf, and B. suipestifer was isolated from its bone marow, which clearly indicates the existence of a blood infection during life. On the other hand, post-mortem contamination of the meat may follow careless handling in the slaughter-house: we may probably regard as examples of this mode of infection cases of meat poisoning in which one part of the animal (e.g., a leg) causes disease, whereas the remainder of the carcase is eaten without ill effect.

Illness in man caused by meat infected *intra vitam* is more serious but less common than that due to the post-mortem contamination of meat. It is less frequent because the routine inspection of meat and the laws against emergency slaughter minimise the probability of the consumption of food from a diseased animal. It is more serious because the bacilli are liable to occur throughout the substance of the meat; and it has been shown, more than once, that the ordinary process of cooking does not necessarily kill the bacilli in the centre of a joint of average size or even in a sausage.

In the pig the most important cause of intravital infection with B. suipestifer is swine fever, in which it makes its way into the blood. And Mayer and Tiberti have noticed the simultaneous prevalence of swine fever and of meat poisoning. No such relationship, however, has been observed in this country.

POST-MORTEM CONTAMINATION.

In two only of the outbreaks caused by food derived from the pig was the animal diseased; in most, if not all, of the others the meat must have been contaminated after the animal was killed. It is not difficult to understand the relative frequency of post-mortem contamination in pigs as compared with other animals. They are the only domestic animals used for food in whose intestine B. suipestifer occurs with any frequency. The contamination of the meat with the contents of the pig's intestine through careless handling in the slaughter-house must therefore offer opportunities for its occasional infection with this bacillus. Another possible source of contamination is mice, which not only at times excrete B. suipestifer, but may also be a means of conveying infected (fæcal) material directly to meat in the slaughter-house or elsewhere.

These modes of contamination will affect in the first instance only the superficial layers of the meat, and unless this has been kept long enough to allow of extensive multiplication and spread of the bacteria cooking will destroy the organisms. This point is of considerable importance, since if meat is kept for some days before being cooked and the organisms have penetrated deeply into the meat, which is an admirable culture medium, they are more likely to escape destruction when the meat is eventually cooked. It has been noticed, in fact, that meat infected with B. suipestifer, which was harmless when cooked and eaten at once, caused illness when the remainder was cooked and eaten two or three days later. This is possibly the explanation of the fact that in this country pork pies and sausages have been responsible for many of the outbreaks of meat poisoning caused by B. suipestifer. But the processes involved in the preparation of these foods further tend to a uniform distribution of the bacilli, and therefore increase their chance of escaping destruction by cooking.

The difficulty of tracing the infection of the meat to its source is often very great, as is shown in a report by Pick and Thomson on a recent outbreak at Chesterfield. The illness was caused by the consumption of pork pies, and B. suipestifer was obtained from the pies and the patients. The pies appeared good, and the conditions of manufacture were excellent; but the premises used for slaughtering and gut-cleaning and those used for preparing the pies and jelly were not completely separated. The only opportunities for the contamination of the food were the infection of the jelly, either while being prepared or when placed to cool. The authors believe that the jelly was contaminated when it was cooling; during that time it was placed in a passage joining the slaughter-houses to the premises in which the pies were made. They trace the infection of the jelly to contamination by hand or by dust.

We may conclude that post-mortem contamination of meat with the contents of the pig's intestine is probably the usual cause, although the actual method of infection in any given case is often difficult to ascertain. The possibility that mice and flies may contaminate meat cannot be excluded, but definite evidence on this point is lacking. The infection of meat by human carriers of B. suipestifer is unknown.

II.—B. ENTERITIDIS (GAERTNER).

Gaertner's bacillus has always been accepted as a cause of meat poisoning. This belief is fully confirmed by more recent evidence as to its distribution and by two cases of infection which are almost comparable with laboratory experiments. In one instance sausages had given rise to symptoms of meat poisoning. The inspector of the slaughter-house did not believe that the illness was caused by the sausages, and in order to demonstrate their harmless nature he consumed a considerable quantity of them. Within a few hours he was seized with acute gastro-enteritis and died; B. enteritidis was isolated from his organs and from the sausage. In a second case a cow was injected intravenously with B. enteritidis (Gaertner) which was isolated from a recent epidemic of meat poisoning and was killed 20 minutes later. A portion of the meat was kept for three days at room temperature and was then found to contain the bacillus in large numbers. This meat was deliberately eaten by 53 people, of whom 15 became ill; fortunately no deaths occurred.

DISTRIBUTION.

The difficulties which have been discussed with regard to the distribution of B. suipestifer hardly arise in the cases of B. enteritidis (Gaertner), since it can be readily identified by its agglutination reactions. It occurs very rarely either in the excreta of healthy men or in those of individuals suffering from diseases other than meat poisoning. In this country Savage examined the fæces of 58 persons, some healthy, others suffering from enteric fever. From one of the latter B. enteritidis (Gaertner) was isolated; the remaining 57 cases were negative. It was also isolated on four occasions by Morgan in the course of his inquiry into the causation of summer diarrhœa, in which over 300 samples of fæces were examined. Quite recently Dean has obtained it from the gall-bladder and from the stools of a patient suffering from gall-stones. With the exception of these cases it has not been obtained in man apart from meat poisoning; and the investigation by Bainbridge and O'Brien of the organisms isolated from the fæces of about 300 enteric convalescents yielded a completely negative result. The careful work of Aumann indicates that B. enteritidis (Gaertner) is equally infrequent in Germany. He found it on 18 occasions during the examination of 765 samples of human excreta. In many of these the presence of the bacilli was associated with the symptoms of meat poisoning.

It cannot be regarded, therefore, as a normal inhabitant of the healthy human alimentary canal.

Nor is it present at all frequently either in the excreta or tissues of domestic animals or in food. Müller showed, for instance, that although pyæmia and septicæmia are quite common in domestic animals these conditions are hardly ever caused by B. enteritidis (Gaertner). There is, indeed, little or no evidence that this organism passes a saprophytic existence even in the domestic animals, since, as a rule, it has been found only in animals definitely suffering from disease. A large proportion of the animals were either calves or cows, and in many of them the illness of the animals, as far as could be observed, was caused by it. The distribution of the bacillus in other than domestic animals is very imperfectly known. There seems no doubt, however, that it may give rise to epizootics in guinea-pigs (Bainbridge and O'Brien) and in rats and rabbits (Bainbridge, Boycott, Durham). It has occasionally been isolated from mice, and is also a very frequent inhabitant of the alimentary canal of healthy grey rats, being met with whenever any large body of rats is examined bacteriologically. According to Uhlenhuth, indeed, B. enteritidis (Gaertner) is normally and constantly present in rats. It may well be that the rat's intestine is the true home of this organism, and that it reaches the alimentary canal of cattle and other domestic animals through the contamination of their food or bedding by rats. The fact that when B. enteritidis (Gaertner) is found in the domestic animals the latter are usually ill, and that it is seldom isolated from healthy cattle lends colour to this hypothesis, the more so as the bacillus is distinctly pathogenic, at least for calves. But the matter needs fuller investigation.

These points may be summarised as follows: 1. B. enteritidis (Gaertner) is frequently present in the alimentary canal of grey rats. 2. It is seldom isolated from the alimentary canal of healthy men or of the domestic animals or from food.

Occurrence in Meat Poisoning.

The total number of outbreaks of meat poisoning in man caused by B. enteritidis (Gaertner) is probably very large. There are at least 30 in which it has been definitely isolated either from patients or from the infected meat. Many of the strains isolated by earlier workers are still in existence, and their identity with the original strain of Gaertner has been confirmed in recent years. In 21 of these the organism was isolated from the patients—twice from the blood, 19 times from the spleen or other organs or from the excreta. In 22 it was isolated from the meat which caused the illness. In 9 cases the patient's serum gave a positive reaction for the bacillus.

Epidemiology.

It is impossible to deal fully with the epidemiology of these outbreaks, but attention may be called to one or two important points. I have records of 24 outbreaks in which the origin of the meat causing the outbreak and the condition of the animals from which the meat was derived are definitely stated. In 16 of these the meat was derived from cattle, in 4 from horses, and in 4 from pigs. In 16 instances (cow 13, horse 3) the animal whose flesh was consumed was either stated to be ill or was slaughtered in emergency; the latter may be regarded as tantamount to evidence of illness. The more frequent forms of disease among the cattle were either fever after calving or calf diarrhœa. In one or two cases definite evidence of the existence of septicæmia was afforded by the isolation of B. enteritidis (Gaertner) from the bone marrow of the animals. Intravital infection of the meat seems, therefore, to be more common than post-mortem contamination. In this respect outbreaks of meat poisoning caused by B. enteritidis (Gaertner) differ from those caused by B. suipestifer, since in the latter the meat is generally infected post mortem. This difference may, perhaps, account for the higher mortality (already referred to) observed in outbreaks caused by B. enteritidis (Gaertner). It is not unreasonable to expect that, owing to the more uniform distribution of the organisms throughout the meat, and therefore to increased opportunities for multiplication in intravital infection, the number of ingested bacilli would be greater than in a superficial post-mortem infection of the meat. It may be, however, that B. enteritidis is always more pathogenic for man than B. suipestifer. It is clear that the most usual source of infection is meat derived from diseased animals, but other possible modes of infection of the meat may be briefly considered. They include the post-mortem infection of the meat either by careless handling in the slaughter-house or by human carriers of B. enteritidis (Gaertner) or by animal carriers. It seems unlikely that meat is often contaminated post mortem with B. enteritidis (Gaertner) through being allowed to come into contact with animal excreta containing this organism, since it is so rarely present in healthy domestic animals, but this possibility cannot be entirely excluded.

Human Carriers.

Nor is there any evidence that illness has ever been caused by meat infected by human carriers of B. enteritidis (Gaertner). Gaertner and others have recorded secondary cases of illness arising in the course of an epidemic of meat poisoning, and apparently caused by contact with patients who had eaten the infected meat. These contact cases occurred among people who had not eaten the meat, but were associated with the patients originally attacked. But infection of this kind has been met with only during the course of the epidemic; and the infection of meat by convalescents or by chronic carrier cases has never been observed. The existence of human carriers of B. enteritidis (Gaertner) is, in fact, practically unknown at present, the only definite instance being that recently described by Dean. In a case of suppurative cholecystitis due to gall-stones he obtained B. enteritidis (Gaertner) from the bile and from the gall-stones, and also from the stools one week and again three months after the operation. The patient's serum agglutinated this bacillus at a dilution of 1 in 40. There seems no reason for supposing that this patient had ever been the source of any infection in other people. A case of this kind undoubtedly indicates the possibility that infection by B. enteritidis (Gaertner) may take place through human agency as well as from meat; but such an event has not been observed.

Animal Carriers.

The occurrence of B. enteritidis (Gaertner) in healthy rats, and to a less extent in mice, and the occasional epizootics observed in these animals raise the question as to how far they are responsible for the post-mortem contamination of meat. Their frequent presence in slaughter-houses and places where food is stored seems to offer opportunities for infection of this kind. No definite proof of such infection has as yet been brought forward, possibly because it has not been carefully sought for. We have seen, however, that the rat is an important reservoir for this bacillus; and it ought to be taken seriously into consideration as a factor in the infection of meat. It is not known with certainty, however, that the strains of B. enteritidis (Gaertner) occurring in the rat are pathogenic for man, although there is a strong presumption that this is the case. Boycott has made some observations on the relative pathogenicity of strains of this bacillus isolated from animals of one species for animals of the same or of another species. He found, on the one hand, that a strain of B. enteritidis (Gaertner) isolated in the course of an epizootic among rats was highly pathogenic for rats, but only slightly so for guinea-pigs; on the other hand, a strain of the same organism isolated during an epizootic among guinea-pigs was extremely pathogenic for guinea-pigs, but much less so for rats. He is disposed, therefore, to regard the strain of B. enteritidis (Gaertner) which occurs in a given animal species as possessing more or less specialised pathogenic power for that species. This observation is clearly of extreme importance, but it does not follow that man is insusceptible to organisms of animal origin—indeed, it is certain that he is in some cases susceptible to such organisms. The variable pathogenicity of a given organism for different lower animals has very little bearing on its possible pathogenicity for man. The increased pathogenicity for rats of the organism isolated during an epizootic among rats may well be a specialised effect resulting from the repeated passage at short intervals through animals of the same species. In this connexion it may well be mentioned that the study of epizootics in the lower animals caused by B. enteritidis (Gaertner) seems to show the mode of the spread of infection in them differs from that in man.[2]

Although the mortality in such epizootics is extremely high, the way in which infection spreads is not clear; the organism isolated from the animals is often intensely virulent

[2] This is true also as regards B. suipestifer.

for healthy animals when injected intraperitoneally, but hardly at all pathogenic when given by the mouth. In one such epizootic occurring in guinea-pigs B. enteritidis was isolated from the animals which died. One cubic centimetre of a 24-hour broth culture when given with food failed to kill healthy guinea-pigs, whereas 1/10000 c.c. of the same culture given intraperitoneally caused death within a week. It is difficult to believe, therefore, that in these cases infections spread by way of the alimentary canal, although no alternative mode of infection has yet been demonstrated. On the contrary, in epidemics in man caused by B. enteritidis (Gaertner) infection appears invariably to take place through food.

Further, bacterial viruses have been extensively employed during the last few years for the destruction of rats; many of the viruses are either pure cultures of B. enteritidis (Gaertner) or consist of foodstuff containing this bacillus. Handson and Williams have reported an outbreak of acute gastro-enteritis which they regard as caused by food which had been infected by one of the viruses. No *direct* evidence of such infection was obtained, but the epidemic occurred among persons who took their meals in the room in which the virus had been placed, the presumption being that infected animals (mice) had contaminated the food. Outbreaks of disease in man traceable to infection by a virus are, however, very infrequent, although the distribution of the viruses by unskilled persons must almost inevitably expose those who handle them to some risk of infection. The actual mode of contamination post mortem is therefore very difficult to demonstrate in any given case, although it undoubtedly occurs from time to time; animal carriers are probably the most important factor.

Finally, reference must be made to milk as a cause of meat poisoning (using this term in the broad sense already indicated). An outbreak recently occurred in which more than 100 persons were almost simultaneously affected. The symptoms were those of acute gastro-enteritis and in some cases were very severe, although no deaths occurred. The illness was confined to those who drank the milk from a cow which had recently calved and was ill at the time of the outbreak; it died a few days later. Gaertner's bacillus was twice isolated directly from the milk and also from the patients. There was a strong presumption that the cow was suffering from infection with this bacillus which reached the milk either through the mammary gland or from the animal's excreta. This outbreak is unique in being, so far as I know, the only instance in which B. enteritidis (Gaertner) has ever been isolated from cow's milk.

The main facts regarding meat poisoning may be summarised as follows:—

1. B. suipestifer and B. enteritidis (Gaertner) are rarely found in the healthy human alimentary canal. Their usual habitat is the intestine of certain of the lower animals; B. suipestifer occurs chiefly in pigs and at times in mice, whereas B. enteritidis (Gaertner) is found frequently in rats, occasionally in cattle, and rarely in other animals.

2. In outbreaks of meat poisoning caused by B. suipestifer the meat has usually become infected after death; in the majority of cases it is derived from pigs. Intravital infection also occurs.

3. In outbreaks caused by Gaertner's bacillus the meat has frequently been obtained from animals which were ill when slaughtered. In some cases the contamination of the meat doubtless occurs after death. In 16 out of 24 outbreaks the meat was derived from cattle.

4. There is but little evidence that ptomaines play any important part in meat poisoning; the majority of the outbreaks are due to meat infected either with Gaertner's bacillus or with B. suipestifer.

OTHER DEFINITIONS OF PARATYPHOID FEVER.

We may now consider two other definitions of paratyphoid fever—namely, that accepted in Germany and that recently suggested by Firth.

1. At the present time the term is used by German writers in a sense widely different from that in which it has been employed in these lectures. It is applied to all forms of disease in man which are associated with the presence of any member of the Salmonella group (with the exception of B. enteritidis (Gaertner)). Some workers even describe the illness caused by B. enteritidis (Gaertner) as "Gaertner paratyphus." Those who accept this definition entirely ignore the varying nature of the clinical symptoms which may be present, and describe as paratyphoid fever, on the one hand, an acute outbreak of acute gastro-enteritis obviously caused by the consumption of infected meat, and, on the other hand, an illness not caused by food and clinically indistinguishable from enteric fever.

This definition, therefore, is based solely on bacteriological grounds, no account being taken of the clinical or epidemiological characters of the illness with which the bacilli are associated. The fundamental fact underlying this conception of paratyphoid fever is that German writers do not recognise the distinction between B. paratyphosus (B) and B. suipestifer. They have made practically no use, certainly no systematic use, of either the absorption or the complement deviation methods which are essential for the identification of these two organisms. Consequently they use the term "paratyphoid" bacillus to describe organisms which can be readily shown to be either B. paratyphosus (B) or B. suipestifer.

Since they do not admit the distinction between these two bacilli, and do not use the methods necessary for that purpose, German writers have naturally failed to notice that they have a very different distribution in nature and give rise to dissimilar clinical symptoms. These writers, in point of fact, include under the term "paratyphoid" bacillus two organisms, and under the term paratyphoid fever two diseases. The unsatisfactory nature of this definition has been partially admitted by some German workers. Hübener, for instance, describes two forms of paratyphoid fever—one caused by the consumption of meat, and one not so caused. But this classification is very inadequate, and the foregoing definition seems to have no advantages and many drawbacks. It has tended to obscure the whole subject, and might with advantage be abandoned.

[Reference ought perhaps to be made to a form of "paratyphoid" fever which is said to be caused by B. paratyphosus (C). In some cases the symptoms resembled those of enteric fever; in others they were those of acute gastro-enteritis. The bacilli which were isolated resembled B. paratyphosus (B) in their cultural characters, but were not agglutinated by B. paratyphosus (B) serum. The fermentation reactions of the organisms do not appear to have been very thoroughly examined, and those who described them do not seem to have realised that the human alimentary canal normally contains organisms which in their cultural characters closely approach the members of the Salmonella group. This fact has been demonstrated very clearly by Morgan in a careful examination of the non-lactose fermenting bacilli present in human stools. He found that many of the cultural characters of these organisms differed very slightly from those of B. paratyphosus (B), although they could at once be distinguished from it by agglutination tests. This observation has been confirmed by Savage. It is possible, therefore, that the organisms which have been described as paratyphosus (C) had no causal relation to the illness with which they were associated, and were merely normal saprophytic inhabitants of the human alimentary canal.]

2. Another definition of paratyphoid fever has recently been advocated by Lieutenant-Colonel R. H. Firth, R.A.M.C., who suggests that the term should be limited to the disease caused by B. paratyphosus (A). His reasons for this definition are, first, that in Europe the term paratyphoid fever is often applied to cases of acute gastro-enteritis following the consumption of infected meat, and, secondly, that B. paratyphosus (B) does not belong to the "paratyphoid" group, but causes the symptoms of meat poisoning. He appears, therefore, to be of the opinion that the cases which clinically resemble enteric fever are invariably caused by B. paratyphosus (A), and that the statements made as to the presence of B. paratyphosus (B) in such cases are erroneous. It is perfectly clear, however, from Savage's description that B. paratyphosus (B) can cause an illness clinically indistinguishable from enteric fever, or from the disease caused by B. paratyphosus (A). Similar cases have been described by Boycott, Schottmüller, Conradi and Jürgens, Sacquepée and Bellot, Rolly, and many others. Moreover, almost every complication which follows paratyphoid (A) fever has been observed in the course of the illness caused by B. paratyphosus (B). Lieutenant-Colonel Firth has apparently been misled by the confusing connotation of the term paratyphoid bacilli used by German writers;

and all the evidence goes to show that paratyphoid fever can be caused by either of these bacilli.

SUMMARY AND CONCLUSIONS.

The evidence which has been placed before you makes it clear, I think, that meat poisoning and paratyphoid fever are distinct diseases (Table IV.). In the first place, they are

TABLE IV.

—	Paratyphoid fever.	Meat poisoning.
Causal organisms	B. paratyphoid (A) and (B)	B. suipestifer and B. enteritidis (Gaertner).
Latent period ...	8 to 18 days.	Usually 12 to 48 hours.
Clinical picture...	Resembles enteric fever.	Acute gastro-enteritis.
Habitat of causal bacilli	Human alimentary tract.	Alimentary tract of certain lower animals.
Mode of infection	Human carriers.	Contaminated meat.
Human carriers...	Common.	Practically unknown.

caused by different bacilli, which (though closely allied) can be distinguished by appropriate methods. Secondly, the distribution of the organisms which cause paratyphoid fever is quite unlike that of the organisms which cause meat poisoning. Thirdly, paratyphoid fever is spread by human bacillary carriers, whereas meat poisoning results from the consumption of food which is derived from infected animals or is contaminated by animal agency. Finally, the clinical pictures of the two diseases are usually quite dissimilar. It is true that, on the one hand, B. paratyphosus (A) and (B) have, although very rarely, been met with in cases of acute gastro-enteritis, and that, on the other hand, the illness following the consumption of meat infected with Gaertner's bacillus or B. suipestifer may take the form of pyrexia lasting two to three weeks. But I do not attach much importance to these exceptional cases, partly because they are exceptional, but still more because abdominal infections seem unusually liable to variability in their clinical manifestations, a case in point being enteric fever. It may, however, be admitted that the boundary-line between meat poisoning and paratyphoid fever is less well defined in regard to their clinical character than in regard to their epidemiology, and possibly they may eventually prove to be more nearly akin in some respects than now seems to be the case. In these lectures the differences rather than the resemblances between these two diseases have been emphasised, because at the present time this point of view appears the more likely to yield fruitful results in their treatment by preventive measures.

THE DIFFERENT FORMS OF THE HUMAN ELECTROCARDIOGRAM AND THEIR SIGNIFICATION.[1]

BY PROFESSOR WILHELM EINTHOVEN, M.D.,
OF LEYDEN.

THE application of electrocardiography to clinical examination gives valuable data in two different ways. In the first place, it shows the time relations between the action of the ventricles and the auricles. The difference in time between the contraction of these two parts of the heart can be measured easily and accurately. Diseases such as Stokes-Adams's, in which the auricles have a rhythm different from that of the ventricles, and which sometimes give difficulties when examined by the older methods, are always immediately recognised, electrocardiographically. And further may be mentioned that a new insight has been obtained into several other diseases, among which auricular fibrillation takes a prominent place.

But this evening we shall pass over this first group of symptoms, and we shall limit our attention to the second one, which is concerned with the form of the EKG. If this form is perfect, it must be the exact expression of the changes in potential difference which take place between two parts of the human body. It is self evident that a perfect form can only be obtained by means of a perfect instrument, and it need not be mentioned that such an instrument does not exist. The capillary electrometer is not rapid enough when made sufficiently sensitive, and therefore not suitable for clinical purposes. The oscillograph suffers from the same fault, although in a less degree, and has, moreover, the great disadvantage that the movements of the recording mirror are oscillatory. On the contrary, the string galvanometer is in general sufficient for clinical purposes, and by means of this instrument we are able to approximate the exact form of the EKG. so closely that the remaining divergences from it become practically imperceptible.

Not every model of the string galvanometer is equally suitable. Even if we have at our disposal a good instrument in all other respects, the correctness of the work done with it depends in a high degree upon the qualities of a small part of the apparatus, the string, and we have further to take into consideration the magnification and the sensitiveness used.

How is the clinician to know if the curves which he has obtained with the instrument are reliable reproductions of the electrical variations under investigation? He can, it is true, correct the curves obtained by means of data determined from the properties of the instrument, and which are to be found by means of control curves. But such a correction requires a fairly detailed calculation and a reconstruction of the curve, for which reason he will be loth to apply it. And happily this is unnecessary in most cases. It is only necessary to record a control curve in such a way that an equal resistance from a rheostat is introduced into the galvanometer circuit in place of the body resistance, which usually has a value of from 1000 to 2000 ohms.

The tension of the string must be so regulated that an excursion of the image of the string of 1 mm. is equal to 10^{-4} volts. At a given moment a constant potential difference is thrown into the circuit. If the string reaches its new position of equilibrium within about 0·01 second or less, the instrument is rapid and at the same time sensitive enough for recording EKG.'s with sufficient accuracy. The deviations from an ideal EKG. which a curve recorded under these conditions exhibits are so small that in the great majority of cases they may be neglected.

To prove this we reproduce in Figs. 1 and 2 two EKG.'s which were taken from the same person by lead I. The sensitiveness of the galvanometer was accurately adjusted in both records, so that 1 scale division corresponded to 10^{-4} volts. All other conditions were also kept the same as nearly as possible, with the one exception that in recording Fig. 2 a magnification was used twice as large as in Fig. 1. Therefore the string was stretched twice as much in Fig. 2, and in accordance with this the duration of a deflection was reduced to half.

It is possible to determine the duration of a deflection to a certain degree by means of Fig. 3, which was recorded immediately after Fig. 2 upon the same photographic plate. A resistance of 2300 ohms was introduced into the galvanometer circuit from a resistance box, this resistance being equal to that found for the body of the person investigated under the conditions of the experiment. The introduction of a potential difference of 3×10^{-3} volts causes a deflection of 3×10 scale divisions, and each deflection is completed in about 0·5 scale divisions—i.e., 0·01 second. The control curve for Fig. 1, which is not reproduced here, shows deflections requiring twice as much time for their completion—i.e., 0·02 second.

Notwithstanding this important difference in deflection time, Figs. 1 and 2 show EKG.'s whose forms agree in all details, and whose various peaks have the same absolute heights within the errors of adjustment—i.e., within a few tenths of a scale division.

We are now justified in making the following conclusion. If the movements of the string could be made 10 or 100 times faster, the sensitiveness remaining the same, or even if, theoretically spoken, an instrument were available with an infinitely small deflection time, the form and dimensions of the recorded EKG.'s would not be thereby perceptibly changed.

On the other hand, if the movements of the string are sufficiently retarded, the form of the EKG. will also be altered. This is illustrated by Fig. 4. This reproduces the EKG. of the same person taken under the same conditions. The sensitiveness of the galvanometer is, just as in Figs. 1 and 2, accurately regulated so that a deflection of the image of the string of 1 mm. corresponds to 10^{-4} volts. But the

[1] A paper read before the Chelsea Clinical Society on March 19th, 1912.

string moves much more slowly, and we now see that all the peaks of the EKG. are reduced in size, whilst the ratio of the peaks to one another is markedly changed.

Allow me to make a comparison here of the requirements to be demanded of the galvanometer and the accommodation of the eye. A definite adjustment of the eye corresponds to a definite distance from an object that must be focussed sharply. Therefore two objects at different distances from the eye can not form absolutely sharp images at the same time, but the physician knows that if the image of an object at 6 metres distance is sharp, the diffusion circles caused by points farther removed are so small that they may be neglected. The accommodation for infinite distance does not differ practically from the accommodation for 6 metres. In the same way we may say that an EKG. recorded with a galvanometer, of which the deflection time is about 0·01 second, does not differ practically from the same EKG. recorded with a galvanometer whose deflection time is infinitely small.

Within these limits the form of the EKG. is independent of the instrument used, and every EKG., when and where it may have been recorded, is immediately comparable with every other EKG.

A parallel can be drawn between image formation in the eye and the recording of the EKG. in still another direction. Suppose that the accommodation of the eye is faultless in a certain case. Even then the retinal image will not be absolutely sharp and exact. The errors of spherical and chromatic aberration, and of defective centration inherent in all optical systems are also found in the eye; and, moreover, the diffraction of the light rays suffices to exclude the formation of an exact image. In the same way there are sources of inaccuracy in the recording of the EKG.; their influence may be decreased, it is true, but can never be completely avoided. I have here in mind not so much the dexterity of the observer, who must regulate the tension of the string exactly, so that the curves may be recorded in absolute measure, as the unavoidable changes in resistance, which the human body offers to the electrical current.

We must make a distinction between the real and the apparent resistance in measuring the resistance of the body. The real resistance is measured by means of an alternating current, in the same way as the resistance of an electrolyte is determined, whereas the apparent resistance is found by making use of a constant current. Under certain conditions the apparent resistance can have a value of more than twice as much as the real resistance, and the question arises, which resistance are we to take into account when regulating the tension of the string. For example, we wish that a deflection of the image of the string of 1 cm. shall exactly represent 1 millivolt, when the human body is in the galvanometer circuit. If the body resistance is large, the string must be relaxed a little; if on the other hand the body resistance is small, the string must be stretched somewhat more tightly, all other conditions remaining equal.

In case the difference between the apparent and the real resistance of the body reaches an important value, the sharp peak R of short duration will be too high in relation to the slow wave T, this being an error which is just the opposite of the error produced by a slow instrument.

How can we best reduce these errors and how large is the error remaining finally? In the first place we must make the resistance of the body as small as possible by putting those parts from which the current is lead off, the hands and the foot, deeply into a strong salt solution. Under these conditions the difference between real and apparent resistance is also reduced to a minimum. Further we must use an instrument with a thin string, thus with a comparatively large internal resistance, so that the variations of the body resistance will only have a small influence upon the current strength.

In regulating the tension of the string we can make use of a rheostat resistance, the value of which is the mean of the real and the apparent body resistance. The difference between these two values need not be larger than 400 ohms under the above-mentioned favourable conditions, so that the deviation from the mean will not be more than 200 ohms. If we take the resistance of the string to be 10,000 ohms the maximum error in the dimensions of the curves is 2 per cent.

These errors are much less in reality, because peak R is not recorded in an infinitely short time and peak T not in an infinitely long time. Moreover, an error of 2 per cent. in the absolute values of the potential difference is so small that it may as a rule be neglected in physiological as well as in clinical investigations. The error would be 0·4 mm. for a large peak R of 20 mm. height, and only 0·1 mm. for a large peak T of 5 mm.

Although we cannot attain an absolute accuracy at present, yet we may consider an EKG., when properly recorded, the exact expression of the changes in potential difference, just as we may consider the retinal image an exact reproduction of the object observed.

The Form of the Curve in Connexion with the Different Leads.

It is desirable to apply three leads in electrocardiographic investigations: (1) from the two hands, across the body; (2) from the right hand and left foot, obliquely; (3) from the left hand and left foot, lengthwise. The galvanometer must be connected to the human body in such a way that the image of the string is deflected upwards when the base or the right half of the heart is negative in respect to the apex or the left half.

Each of the three leads produces an EKG. of special form so that each has its own peculiar value. Lead I has the advantage of being applied easily in the clinic. The curve obtained is of especial value in judging peak T and certain atypical EKG.'s. With lead II the peaks are usually larger. Especially the auricular peak P is clearly shown and may therefore be best studied with this lead. In judging the wave T in cases of cardiac insufficiency lead II has the same importance as lead I. On the other hand, many atypical forms of the EKG. can be studied better with lead I than with lead II.

Lead III is most suited for diagnosing hypertrophy of the right or left ventricle. Atypical EKG.'s are also well shown by lead III. On the other hand, the wave T obtained by this lead is of no value in drawing conclusions as to the functioning of the heart. T_{III} has different heights in normal EKG.'s, is often negative, and often practically absent.

The Connexion between the Forms Obtained with the Three Leads.

From the nature of the case there must be a connexion between the curves obtained by the three different leads from the same person. If two forms are known, the third may be calculated from them. The difference between the electrical tensions of leads I and II must be equal to the electrical tension of lead III. This may be formulated: lead II − lead I = lead III. The formula holds good only in case the current which is flowing through the galvanometer exercises no influence upon the tensions present at the extremities. As a matter of fact, this influence is so small that we may neglect it without making a perceptible error. For the total resistance of the circuit containing the galvanometer and the human body is very large when compared to the resistance of the heart muscle. We may therefore assume *a priori* that the formula is exact.

We might attempt to make use of this formula when examining patients, for the sake of simplicity contenting ourselves with the recording of two leads. The curve of the third lead would then be constructed from the other two. Although the construction seems to be easy, yet its execution gives difficulties, the main cause of which lies in the fact that the peaks, which we generally indicate by means of the same letters, do not occur in identical phases of a heart's revolution. It is possible to show this in various ways—e.g., by comparing the distances between the peaks P, R, and T in the curves obtained by lead I with the corresponding distances in the curves obtained by lead II and lead III. It then appears that the peaks mentioned stand closer to one another in lead I.

A superficial examination of certain curves—for example, those of Fl. (Figs. 5, 6, 7), in which the three leads exhibit fairly large differences—might appear to favour a doubt as to the practical validity of the formula. But it is not difficult to show that the rule is also in accordance with the facts.

The simplest way to do so would be to record two or three curves by the various leads immediately under one another. Two or three large string galvanometers should be used and the images of the three strings should be projected by means of mirrors upon the same photographic plate. It seems to me that the use of a small model of the galvanometer, in which two or more strings are placed in the same magnetic

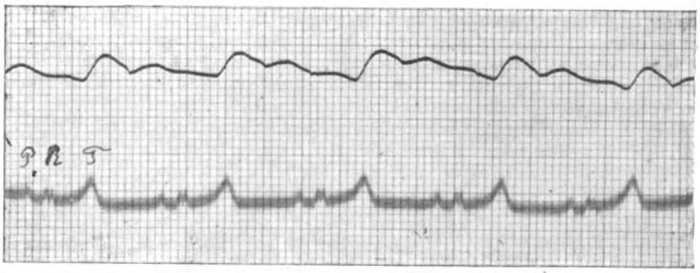

FIG. 9.—Wi. Lead I. A remarkable *QRS*-group.

* If not otherwise mentioned the abscissæ and the ordinates in all figures have the same value as in Fig. 5.

field, or the use of an oscillograph containing a number of mirrors, is not suited to this purpose, because these instruments do not reproduce the form of the EKG. accurately, whereas it is especially desirable in this case to have the form as exact as possible.

Another method has been applied by Fahr and de Waart. They have recorded the EKG., together with the heart sounds, according to the method of Kahn. The EKG.'s obtained by the three leads were taken from the same person under exactly the same conditions, the curve of the heart sounds being combined with each EKG. By this means a fixed point falling always in the same phase of a cardiac cycle could be marked, and corresponding phases in the curves of the various leads could be accurately identified.

The investigation of Fahr and de Waart shows that the ventricle EG. when obtained by leads II and III begins, as a rule, a little earlier than when obtained by lead I, whereas the summit of R_I is reached a little earlier than the summits of R_{II} and R_{III}. If we make use of these data it is not difficult to show the validity of the formula, even in complicated forms of the EKG. To illustrate this we have reproduced in Fig. 8 QRS-group of the EKG.'s of Fl. shown in Figs. 5, 6, and 7. The three curves are constructed in the same system of coördinates. The abscissæ have been increased 4 times more than the ordinates, so that the whole figure has been stretched in the direction of the abscissæ; one scale division of the abscissæ represents 0·01 sec., one scale division of the ordinates 10^{-4} volts. Each vertical line corresponds to one phase of a cardiac cycle and the formula lead II − lead I = lead III holds good for every phase. We see that the peaks Q_{II} and Q_{III} begin 0·01 sec. before R_I and fall in the anacrotic branch of this peak. The whole peak S_I falls in the catacrotic branch of R_{II} and R_{III}, whilst the whole of peak S_{II} only corresponds with the anacrotic branch of S_I.

Similar constructions can be made, as a rule, without great difficulty and can be applied to peaks P and T as well, but it is often difficult to attain a great degree of accuracy. This is especially true when the height of a small peak must be determined from the difference in the heights of two peaks of nearly the same size. If T_I and T_{II} are of approximately the same height, as is often the case, then the value of T_{III}, calculated by means of the formula, is very inexact.

It is thus evident that we should not content ourselves with taking only two leads, for the dimensions of a curve constructed by calculation can be determined not only more simply but also more accurately by directly recording it by the third lead. The great advantage of a construction as in Fig. 8 is the better insight obtained into the QRS-group.

QRS-group.

This group deserves a closer examination because it forms the beginning of the ventricular EG. and shows the path by which the excitation wave is conducted from the auricles to all parts of the ventricular wall. This group takes very different forms in normal hearts, so that it is sometimes impossible to point out the peaks Q, R, and S. The examination of even a small number of curves will show that the inconstant peak Q fails in some EKG.'s, the inconstant peak S fails in others. In some EKG.'s S is as large as R, and in some others both Q and S fail so that only R remains.

We reproduce here an EKG. of Wi. (Fig. 9), who possesses a normal heart. The curves obtained by leads I and II show large peaks R, as is often the case with normal hearts. The curve reproduced above and taken by lead I exhibits an entirely different form of the QRS-group. This group is here represented by a slight elevation, about as high as P and about one-third as high as T. On closer examination it is seen to consist of two small upwardly directed peaks, placed close beside one another. It is impossible to say whether they are Q, R, or S. The same is true of many normal as well as of many pathological curves taken with lead III. A single example of such a $(QRS)_{III}$-group may suffice (Fig. 10).

We have here again two upwardly and two downwardly directed peaks, no one of which may possibly be distinguished as Q, R, or S. T_{III} is negative in the EKG. of this person.

The explanation of the ventricular EG. is based upon this great variability in the QRS-group. As soon as the excitation wave has reached the ventricular walls through the atrio-ventricular bundle and the Purkinje fibres, the ventricular musculature begins to contract in many places at the same or nearly the same time. The atrio-ventricular bundle, according to the investigations of Aschoff-Tawara, consists of a system of muscle fibres, well likened to a tree with its branches. From their origin in the auricular septum to their arborisation in the walls of the lower chambers of the heart, these fibres are separated from the rest of the heart muscles by connective tissue. The bundle does not enter into connexion with the heart musculature excepting with its end ramifications, which are spread over a large surface in the walls of the ventricles, fusing with them at many points. The great variety of forms of the QRS-group is caused by small variations in the architecture and the conductivity of the bundle and the Purkinje fibres, so that the excitation wave in some hearts reaches the right side 0·01 second sooner than the left, or the base sooner than the apex, whereas the opposite sequence occurs in other hearts.

The contraction wave spreads over the whole ventricular musculature within a few hundredths of a second, and all changes in potential disappear temporarily. This happens in the time between group QRS and the beginning of the T wave.

The potential difference indicated by the galvanometer in any given moment is the resultant of the joint potential differences existing at that moment between the various parts of the heart. If we consider the phenomena from this point of view we may agree with Selenin, who regards the EKG. as the algebraic sum of the changes in potential, caused by the contraction of the right and left chambers. We also may agree with Eppinger and Rothberger, who assume that the EKG. is the resultant of the forces in the constrictor fibres and in the longitudinal fibres of the heart musculature. Neither is there any objection to the idea of the EKG. being the expression of the antagonism between base and apex. For we may divide the heart into two arbitrary parts, and the EKG will always be the resultant of the changes in potential differences in these parts. The curve must represent, under all circumstances and in every moment, the algebraic sum of all the potential differences which at that moment are developed in the heart.

Peak U.

We must now point out two peculiarities of the EKG. which up to the present have been considered worthy of only slight consideration. In the first place, the existence of a wave, which comes after the T wave and may have a considerable height in pathological cases. This wave U is also present in the curves from normal hearts, but in these cases it is very low as a rule. Lewis estimates that wave U is present in three-quarters of all EKG.'s taken by lead II. After an examination of my collection of EKG.'s I also conclude that the presence of peak U is very common, at least in half of all persons.

Figs. 11 and 12 are illustrations of EKG.'s with fairly high peaks U, obtained from persons with normal hearts. Fig. 11 is from a sportsman, aged 37 years, with a strong musculature; Fig. 12 is from a well-built young man, 19 years of age, of somewhat more than the average height. Wave U reaches a value of about $0{\cdot}5 \times 10^{-4}$ volts in both curves, but is not of equal height in all heart beats. This wave must be regarded as an inconstant one.

The significance of it and the reason for its inconstancy are for the present not known with surety. The method of recording the heart sounds, together with the EKG., has shown that the second sound is produced almost immediately after peak T is finished. The end of U lies after the second sound, so that there is no doubt that wave U falls wholly or partly in that phase of the cardiac cycle which follows the closing of the semilunar valves. The heart is in diastole after the closing of these valves. But the heart muscle, which does not begin to contract at all points at the same time, does not relax at all points at the same time either. A large part of the heart can have already relaxed, so that the pressure in the heart's cavities may be practically diminished to zero, and at the same time a few fibres may still be in the condition of contraction. Peak U will not have reached its end until these latter fibres are fully relaxed.

The Interval between Auricular and Ventricular Contraction.

In the second place, we wish to direct attention to the position of the galvanometer in the interval between P and the QRS-group. In many cases the string takes the same position here as that held during diastole, so that a horizontal line is recorded at the level of the line of diastole. But in many other cases there is a perceptible difference in the positions of the lines. We wish to illustrate this with only one example (Fig. 13). We see in this figure that the curve between P and the QRS-group lies about 1 mm.—i.e., 10^{-4} volts lower than during diastole. To what must this be ascribed?

Is the conduction through the atrio-ventricular bundle accompanied in this case by the development of a perceptible electrical current, or is a potential difference developed even during the diastole? Have we perhaps to consider a generation of electricity effected by the same causes that produce peak U? For the present we shall not choose between the possibilities mentioned, but shall content ourselves with the information that curves like Fig. 13 are often obtained from persons with normal hearts.

The Influence of the Position of the Heart.

The position of the heart influences the form of the EKG. In electrocardiographic investigations we are chiefly interested, however, in getting a better insight into the *functioning* of the heart, and it is easy to understand that a difficulty must arise in drawing conclusions as to this point from the form of the curve, if a displacement of the organ is sufficient in itself to produce a change in the EKG.

The difficulty is best solved by making ourselves accurately acquainted with the effects of a shifting and a rotating of the heart. The easiest and at the same time the most striking example of the influence of the position of the heart upon the form of the EKG. is offered by a case of situs inversus viscerum. Waller was the first to investigate such a case, and since then a number of other cases have been published. I permit myself here, moreover, to publish a curve taken by Dr. Fahr from a boy aged 7 years by lead I. We see immediately that the peaks of Fig. 14 are exactly the reverse of a normal EKG. If we interchange the conducting wires to right and left hands we obtain a curve which cannot be distinguished from a normal EKG., as is shown in Fig. 15.

Whereas the EKG. in situs inversus may be very easily explained and gives no cause for a more extended discussion, other cases of change in position of the heart are accompanied by more complex phenomena, and these require a more detailed analysis for their understanding. We shall here discuss in particular the deviations in the position of the heart which accompany the movements of respiration.

Movements of the diaphragm participate to a greater or less extent in the respiratory movements of women as well as of men, and the heart must be displaced in the thorax whenever the diaphragm takes a higher or a lower position.

Even before the construction of the string galvanometer Samojloff demonstrated to his classes that increased respiratory movements had a perceptible influence upon the oscil'ations of the mercury meniscus of the capillary electrometer connected with the human body. By lead I the oscillations became larger in the phase of expiration and smaller in the phase of inspiration. Many other investigators have examined the same phenomena. In our description we shall make use of curves which were taken with the help of Vaandrager and later with the help of Fahr and de Waart. In Figs. 16 and 17 we see pieces of a curve which was taken from Bl. by lead I. The upper curve is the pneumogram.

The pneumogram was obtained by recording the movements of a Hutchinson spirometer into which the person under investigation breathed. A movement of the recording lever upwards corresponds to an inspiration, a movement downwards to an expiration. Each scale division of the ordinates represents 250 c.c. inspired or expired air; the amplitude of the oscillations of the pneumogram vary between 11·3 and 11·5 scale divisions—i.e., 2·8 to 2 9 litres. The vital capacity of the person amounted to 4·4 litres; thus the respiratory movements during the recording of the curves were about two-thirds of the vital capacity. These movements were sufficient for our purpose, and at the same time the subject could execute them with ease.

The pneumogram reproduces the changes in the volume of the thorax without practically any delay. This may be shown by means of the trembling of the subject at the height of inspiration. The effect of this trembling caused by the strong muscle contractions necessary for the excessive movements of inspiration is to be seen clearly in the EKG. As soon as the inspiration is ended the oscillations in the EKG. disappear, for the muscles relax and passive expiration begins. We may say that the end of the trembling coincides with the top of the wave of the pneumogram, if we neglect small differences in time—as, for example, differences of five scale divisions, or 0·2 second.

Apart from the form of the EKG. and the height of its peaks there is a striking variation in the heart's frequency during the movements of respiration. I should like to point out that the maxima and minima of the heart's frequency do not correspond with the crests and troughs of the pneumogram. For instance, the longest pause in the heart's action is found at the end of Fig. 16, the shortest pause at the beginning of the same figure, whereas the volume of the lungs is about the same in both places. The volume of the lungs is also the same at the beginning and at the end of Fig. 17, whereas the heart's frequency differs markedly in these places.

The explanation of this phenomenon is generally known; during very slow and deep respiratory movements the gases of the blood change sufficiently to influence the tonus of the vagi, especially at their origin in the medulla. As the maximum and minimum of vagus tonus do not correspond to the extreme positions of inspiration and expiration, the time of the greatest and the time of the least frequency of the heart will also be displaced in respect to these positions. This displacement varies largely from person to person. We have mentioned this circumstance here because it must be taken into account whenever the influence of the respiratory movements upon the form of the EKG. is discussed. For we know that the form and magnitude of peak P as well as of wave T can be materially changed by the action of the vagi.

In Figs. 18 and 19 we reproduce two pieces of a curve, which was taken from the same person by lead III. The influence of the vagi upon the form of peak P is shown very clearly in these figures. After long heart pauses P is small, sometimes diphasic, other times totally negative, whereas P has its normal form and magnitude after small pauses—i.e., with increased frequency and decreased vagus tonus.

The above mentioned facts make it evident that we meet with a difficulty when estimating the influence upon the form of the EKG. of a displacement of the heart caused by the respiratory movements. Peak P is influenced by two factors, and it is not easy to separate them from one another nor to estimate the magnitude of each alone. We shall therefore concentrate our attention upon some other peaks of the curve.

We see from Figs. 16–19 that the peaks of lead I are larger during expiration, whereas by lead III they become smaller during the same phase of respiration. If we consider these facts in connexion with the formula, lead III = lead II —lead I, we must conclude that the changes in the peaks of lead II will be very slight. And this is, in fact, the case with Bl. and with the majority of the persons investigated. The practical result of this is that we must apply this lead when examining a patient if we wish to investigate the form of the EKG. as free from the influence of the respiratory movements as possible.

Further, we wish to remark in the above figures that peaks R and T are both decreased or both increased in the same degree as well in lead I as lead III during the various phases of breathing. Thus the relative heights of the peaks remain the same, so that the curve retains its form.

But similar changes are not observed in all persons. In some persons we find differences which upon superficial examination seem to be wholly irregular and thereby puzzling. We shall first describe some of these differences separately, and shall then try to unite them all under one point of view.

In the first place we shall direct attention to the fact that the changes which peak R undergoes are, in many cases, materially larger than the corresponding changes in T. Figs. 20, 21, 22, and 23 are examples of this. Figs. 20 and 21 reproduce the EKG. of Bak. by lead I. Two pieces have been cut out of the original curve in such a way that Fig. 20 renders that portion of the record taken in inspiratory position, and Fig. 21 renders that portion taken in expiratory position. In this latter figure we see that the enlargement of peak R is materially greater than that of the T wave, whereby the curve receives quite another shape.

An even greater disparity is brought to light in Figs. 22

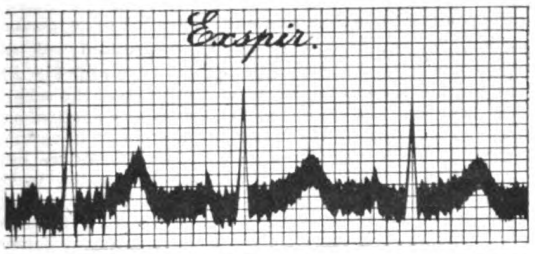

FIG. 21.—Id. Lead I during expiration.

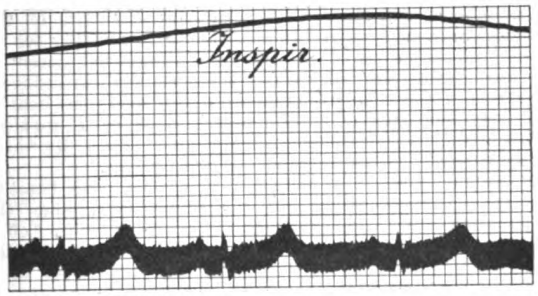

FIG. 22.—Wi. Lead I during inspiration.

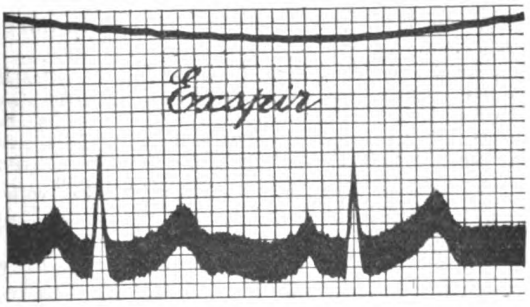

FIG. 23.—Id. Lead I during expiration.

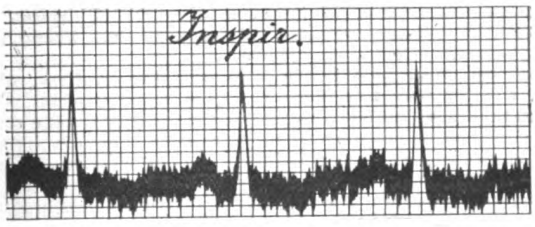

FIG. 24.—Bak. Lead III during inspiration.

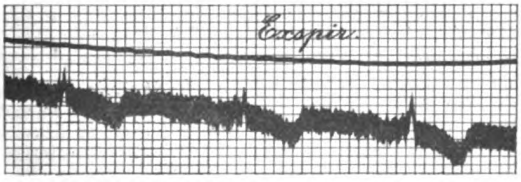

FIG. 25.—Id. Lead III during expiration.

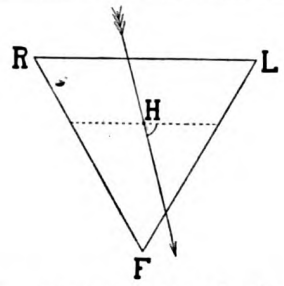

FIG. 26.—Schema of the equilateral triangle. *R* corresponds to the right hand, *L* to the left hand, and *F* to both feet. The heart, *H*, is in the centre. The arrow indicates the direction of the potential differences in the heart. $\alpha = 76°$.

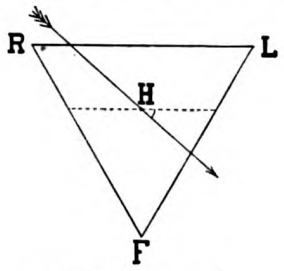

FIG. 27.—Id. $\alpha = 40°$.

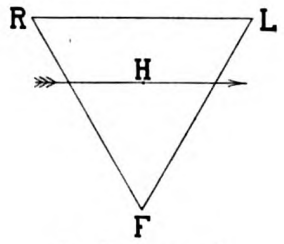

FIG. 28.—Id. $\alpha = 0°$.

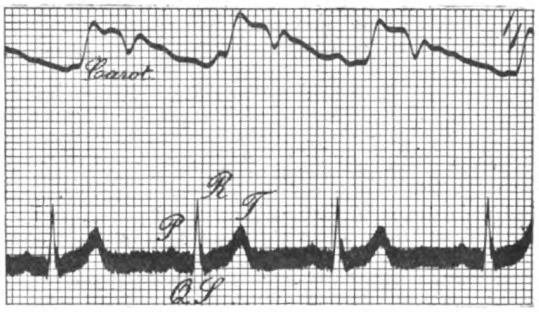

FIG. 29.—Fl Lead I, lying on his left side.

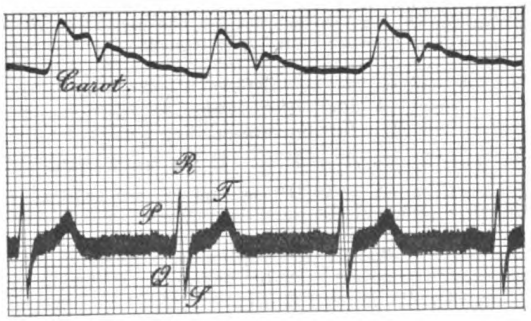

FIG. 30.—Id. with same lead, lying on his right side.

and 23, which were obtained from Wi. Here we have again two pieces of a curve taken by lead I; Fig. 22 corresponds with the inspiratory, Fig. 23 with the expiratory position of the person under investigation. In the first position R is larger than T, in the second the relation is reversed.

Another difference found is that a peak which becomes larger in lead I also increases in lead III. This phenomenon occurs whenever the peaks have opposite directions in the above-mentioned leads. Figs. 24 and 25 furnish an example of this. They reproduce the EKG. in lead III of the same person whose EKG.'s in lead I were shown in Figs. 20 and 21. Wave T is negative in lead III and we see that T_{III} has increased as well as T_I. Phenomena similar to those described above are to be observed in the *QRS*-group.

But we shall now try to explain the apparently so irregular effects of the respiratory movements upon the form of the EKG. In the first place we exclude the possibility that such potential differences as are shown by our curves might be due to accidental causes—as, for instance, the muscle contractions necessary for the respiratory movements, or to a displacement of the electrodes. For if such secondary causes should exercise an influence synchronous with the movements of respiration, then the curved line which reproduces a series of EKG.'s would have to rise and fall in the same rhythm as the movements of breathing. But we see that the line drawn through the heart pauses does not show such a rhythm. On the contrary, it has in many curves an absolutely straight course, as may easily be seen with the aid of the system of square millimetres.

As a second possibility to be taken into account we may mention the influence of a changing body resistance, a hypothesis pointed out by Samojloff. The electrical resistance of the organs surrounding the heart must show during breathing rhythmic changes due to changes in the blood and air content of the chest, and these changes in resistance must necessarily influence the heights of the peaks of the electrocardiogram. But this influence is obviously small, for the curve of lead II shows only slight changes as a rule, whereas the changes produced in lead III are as a rule the opposite of those in lead I. Moreover, the fact that the relation between the heights of the peak is often changed cannot be explained by a change in the resistance of the body.

As a third cause we may mention that the manner in which the heart contracts depends upon the pressure in the thorax. The negative interpleural pressure, which increases during inspiration and decreases during expiration, mechanically influences the circulation perceptibly. But this influence is also insufficient to explain the phenomena described.

The difficulties are solved at once, however, if we apply a schema in which the human body is represented by a plane, homogeneous plate in the form of an equilateral triangle, RLF. (Fig. 26.) From its corners the current is lead off to the galvanometer. R corresponds to the right and L to the left arm, while F indicates the potential of both feet. Thus, a lead from R and L corresponds to lead I, from R and F to lead II, and from L and F to lead III. A small spot H in the middle of the triangle represents the heart. We assume that in a given moment the potential differences in the heart are so distributed that their resultant takes the direction of the arrow drawn in the figure. This direction indicates the direction of the current in the heart. The angle which the arrow forms with the side RL is called α. We shall call the angle positive if, when looking towards the front wall of the chest of the patient, the arrow rotates with the hands of the clock; negative if it rotates in the opposite direction.

We now suppose that the EKG. of a patient has a simple form in each of the three leads, so that the peaks R_I, R_{II}, and R_{III} fall in corresponding phases of a cardiac cycle, and $R_{II} - R_I = R_{III}$. If we transfer the values found with the patient to the schema we are able to determine the direction of the potential difference which has been present in the heart during the recording of R.

The EKG. of Bak. in the position of inspiration may be taken as an illustration. In his curves the following values are found for R: $R_I = 3{\cdot}2$, $R_{II} = 12{\cdot}5$, $R_{III} = 9{\cdot}3$ millivolts. In the homogeneous triangular plate with the heart in the centre these values can only be produced by a potential difference, having the direction of the arrow drawn—i.e., that $\alpha = 76°$.

In the position of expiration we find for the same person: $R_I = 9{\cdot}2$, $R_{II} = 11{\cdot}2$, $R_{III} = 2{\cdot}0$; wherefrom we can calculate that under the circumstances $\alpha = 40$. (*Vide* Fig. 27.)

Thus we are able to demonstrate by means of the schema that the heart has rotated in the chest around a sagittal axis during the movement of expiration. The amount of rotation according to the schema is $\alpha_1 - \alpha = -36°$. As we have reason to believe that the real amount of rotation in the body corresponds sufficiently well for practical purposes with the amount of rotation in the schema we shall hereafter simply consider the direction of the potential difference in the body as parallel to the direction of the arrow in the schema. The way in which α can be calculated from the potential differences recorded need not be explained in details. It may suffice to state that the calculation is simple and can be executed very quickly.

The schema can show more than the direction of the potential difference only. It also makes it possible for us to compare the values of the potential differences present in the heart itself. To make this clearer we shall introduce a new term, "the manifest potential difference in the heart," and when speaking of certain peaks, P, R, or T, we shall indicate them with the figures Pm, Rm, or Tm. By these figures is meant the manifest values of the peaks.

We define the manifest potential difference in the heart as the amount shown in one of the three leads, when the direction of the current between the points of leading off is parallel to the direction of the potential difference in the heart. We here consider only potential differences in a frontal plane. Suppose that a given potential difference in the heart forms the peaks T_I, T_{II}, and T_{III}, and that the direction of the current in the schema is represented by an arrow parallel to the side RL (see Fig. 28), then T_I is the largest of the three peaks, T_{II} and T_{III} being opposite to one another, and each equal to one half of T_I. In this case $Tm = T_I$.

The manifest value of a peak can always be calculated from the height of the recorded peaks and thus can always be expressed in absolute measure—e.g., in tenths of a millivolt. This calculation is also easily and quickly made. If we apply it to peak R of Bak., the dimensions of which have already been given, we find $Rm = 13 \times 10^{-4}$ volts in the position of inspiration, $Rm = 12 \times 10^{-4}$ in the position of expiration.

In another person a rotation of the heart of $-12°$ was brought about by expiration, Rm amounting to 27×10^{-4} volts in a position of inspiration and to 26×10^{-4} volts in a position of expiration. In a third person a rotation of $-20°$ was found, whilst Rm kept the constant value of 20×10^{-4} volts. In all persons examined till now the rotation takes place in the same direction in expiration, whilst the manifest height of R keeps constant within the limits of the errors of the method.

We can investigate the direction and the manifest value for T in the same way as for R. As is to be expected, T is always rotated by the movements of respiration in the same direction as R, but the amount of rotation is not exactly the same. Moreover, the manifest value of T changes—a fact which points out that other factors besides the rotation of the heart are active in the formation of T during respiration. The vagus tonus is one of these factors.

There are good reasons for assuming that the most prominent peaks of the ventricle electrogram, T and R, are brought about by potential differences localised in approximately frontal planes. This is proved by the behaviour of peak S in lead I. When a person lying horizontally upon the left side turns over upon the right side whilst his EKG. is taken, we obtain the striking phenomenon that peak S_I, which is often very small or not present at all in the first position, becomes visible and sometimes reaches a prominent height in the second position. Figs. 29 and 30, both of which were taken by lead I, furnish an illustration of the production of a large peak S_I by the turning of the body on to the right side. Fig. 29, which was recorded while the patient was lying upon the left side, shows a small peak S, which may almost be neglected, whereas Fig. 30, which was

obtained while the patient was lying upon the right side, shows a peak S so large that we are inclined to be astonished that both curves have been obtained from the same person, with the same lead, and with the exception of the body position, under quite the same circumstances.

The most satisfactory explanation of this, upon superficial examination, so puzzling phenomenon is to be found in the assumption that the heart rotates in the chest about the longitudinal axis of the body, when the body itself turns from the right upon the left side. If there is a potential difference in the heart having a sagittal direction, then a slight rotation of the organ about the longitudinal axis of the body can produce a material change in the height of the corresponding peak, and this will be especially well shown by lead I. If the potential difference has exactly the sagittal direction the peak entirely disappears. It is probable that the large differences in S in different persons, as well as its inconstancy, must, as a rule, be explained by this circumstance.

We direct attention to the fact that in Figs. 29 and 30 the peaks P, R, and T undergo hardly any change. If we conclude from the enormous change in S that a rotation of the heart has taken place round the long axis of the body, then we must also assume that the peaks P, R, and T are developed in approximately frontal planes, or in other words, in planes making relatively large angles with the sagittal plane, for thereby it can be most easily explained that under these circumstances the changes in these peaks are so small.

The application of the schema of the equilateral triangle accounts for a number of phenomena here treated of. First it is immediately obvious from the schema that a comparatively large displacement of the heart parallel to itself will only slightly affect the heights of the peaks recorded. This explains the fact that the EKG. of many persons is hardly perceptibly changed or is not changed at all during the ordinary movements of breathing. It also explains the fact that with the exception of peak S, there are only slight changes produced in the EKG., when the body is turned from one side to the other, although we must expect from the anatomical conditions that the heart has hereby taken a lower position in the chest.

The schema explains easily and satisfactorily how the various peaks of the EKG. are often unequally increased or decreased by a change in the position of the diaphragm, and why the curve of lead II shows slighter changes than the curves of leads I and III. A potential difference which is present in the heart and has a direction which in the one position of the heart makes an angle of 80°, and in the other position an angle of 40°, according to the schema, causes the formation of a peak which remains unchanged in lead II, but which is very much altered in lead I as well as in lead III. If this peak in lead II has the value $9{\cdot}4 \times 10^{-4}$ volts in the first position of the heart, it keeps this value in the second position. It increases in lead I from $1{\cdot}7 \times 10^{-4}$ volts in the first position to $7{\cdot}7 \times 10^{-4}$ volts in the second. It decreases in lead III from $7{\cdot}7 \times 10^{-4}$ volts in the first position to $1{\cdot}7 \times 10^{-4}$ volts in the second.

It is equally clear why a peak which has the same direction in leads I and III undergoes opposite changes by a displacement of the diaphragm, whereas it is either increased or decreased in both leads if it has a positive value in lead I and a negative in lead III. This is the case when α has a value between $-90°$ and $+30°$.

With the aid of the schema we are in a better position to judge the form of the EKG. under all circumstances. For instance, it is possible therewith to show that an increased frequency of the heart brought about by bodily exercise is always accompanied by a positive rotation of T and by an increase in the manifest value of this peak. In myodegeneratio cordis and in many cases of auricular fibrillation T is small in all three leads. It need not be said that Tm must also be small under these circumstances.

In cases of hypertrophy of the left ventricle we sometimes find the most prominent peak of the QRS-group in a direction represented by $\alpha = 40°$, whereas in normal hearts the value of α for this peak lies between $+40°$ and $+90°$. We see from these figures that the deformation of the EKG. in this heart affection is not, or not chiefly, caused by a change in the position of the heart. The manifest value of the most prominent peak of the QRS-group in hypertrophy of the left ventricle can reach the enormous value of 26×10^{-4} volts. In hypertrophy of the right heart we obtain, as is well known, EKG.'s of an entirely different form, to which, however, similar considerations may be applied. By means of the schema we can in general differentiate the real changes in the heart's action from the apparent ones, which are only caused by variations in the position of the heart.

Atypical contractions may also be examined with the aid of the schema. They are of great importance in the clinic, and are worthy of a special, detailed discussion, but I must conclude now.

It gives me an especial pleasure to bring to remembrance here that the human EKG. was first recorded by a London physiologist, Augustus D. Waller, who also introduced the term "electrocardiogram" into science; and that Dr. Thomas Lewis, whose extensive researches have been crowned with such exceptional success, was the first man in England who applied electrocardiography to clinical investigations.

The method of electrocardiography is still a young plant. We may reasonably expect that it will continue to bear good fruit.

A CASE OF RUPTURED KIDNEY.

BY A. ADAMS, M.B., CH.B. LIVERP.,
LATE HOUSE SURGEON, LIVERPOOL ROYAL INFIRMARY.

RUPTURE of the kidney is such a rare condition that it becomes a duty to report a case, especially when accompanied by conditions of peculiar interest. Morris collected 26 cases from American and English authors from 1884 to 1896 inclusive, of which 14 died and 12 recovered; and Keen, in 1896, reported 118 cases of subparietal rupture published since 1878. The causes are usually crushes, direct blows, falls from a height, or forcible flexion of the trunk antero-posteriorly or laterally, the most common being by direct violence, by buffer accidents, the passage of wheels over the ilio-costal space, or falling over a hard object, or by a fractured rib penetrating the organ, usually occurring between the ages of 20 and 40 years; it is rare at other ages, being due to occupation risks. A more rare cause is by indirect violence, or simple muscular contraction, and Morris quotes three cases which resemble the case which came under my notice. A man, walking behind a wagon loaded with sacks, observing one falling off, attempted to catch it, and was seized with sudden pain followed by hæmaturia (Clement Lucas). A girl of 14 doubled up her body in jumping, and was seized with severe pain, collapse, and hæmaturia (Caldwell). A soldier when boxing was suddenly seized with pain in his loin and died from ruptured kidney. The cause of the lesion in this type of case has been variously explained, and, as usual, the explanations are unsatisfactory in proportion to their number. Küster showed by experiment that it was due to the hydraulic pressure acting through the full vessels and pelvis causing the kidney to burst; but this explanation does not explain a case of a completely torn across kidney, like the case quoted below, nor the cases where only the fibrous capsule or cortex is torn.

Another explanation given by various authorities is that the kidney is caught between the ribs and crest of the ilium or between the ribs and vertebræ. This should give injuries of the muscle and various other organs as well and it is not generally accepted as a sound theory. Again, some authors say that the kidney is attached to the psoas muscle and in cases of a sudden strain thrown on it, the kidney being unyielding, is torn across, whilst the muscle stretches; but this would not account for the great majority of cases where the kidney lies loosely embedded in the perinephric fat.

The lesion is usually subparietal in adults, due, no doubt, to the bed of areolar tissue and fat in which the kidney lies; but in children the perinephric fat is not developed till after 10 years of age, and the kidney being separated from the peritoneum by the perinephric fascia the peritoneum is almost invariably torn in the rupture of the kidney, thus adding to the complications by opening up the abdominal cavity and increasing the mortality, as shown by the fact

that in Morris's statistics six out of seven cases under 10 years of age died. The symptoms are collapse, vomiting, local pain and tenderness, attacks of ureteral and renal spasm, and disturbance of renal function, hæmaturia, and diminution of urine. The collapse is usually profound and of long duration. The face is pale and drawn and covered with sweat. Temperature is subnormal, the pulse quick and small, and the extremities cold. The aspect of the patient for some hours is discouraging in the extreme. In some cases ecchymoses appear at the root of the penis and over the external abdominal ring (Morris). Testicular retraction due to the severe hæmaturia and the passage of clots in the ureter have been observed. A tumour from the extravasation may occur rapidly, rounded in form and dull to percussion, and fluctuation may be felt. Hæmaturia may be due to simple contusion of the kidney or by transudation. After the effects of the shock have worn off the local pain continues and is increased on respiration. The pulse becomes sharp and rapid, the skin hot and feverish, the tongue furred, and there is nausea with vomiting. The complications are numerous and dangerous: (1) continuous and excessive extravasation of blood, (2) peritonitis, (3) inflammation and suppuration of the perinephritic tissues, (4) occlusion of the ureter, (5) traumatic nephritis, and (6) extravasation of urine. Of these, hæmorrhage is the most common cause of death.

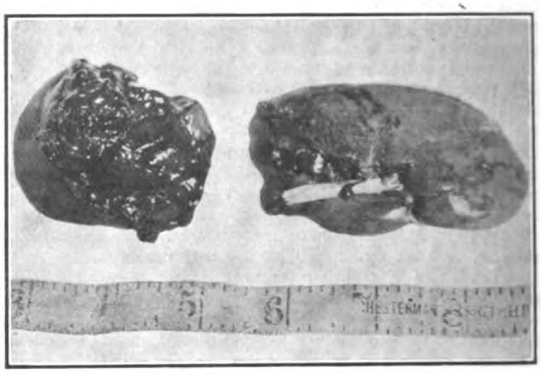
Treatment.—The effects of the shock must be combated by absolute rest, and the patient kept warm; stimulants and solid food avoided and fluids limited. The bowels should be well moved by enemata and morphia given to relieve pain. Ergot is sometimes given to relieve the hæmorrhage, but its use is of more than doubtful efficacy. No attempt should be made to at once remove the blood-clot from the bladder, as the urine has a solvent action on it. As regards operation, each case must be decided on its merits; but Morris advises early interference. In this connexion it is interesting to note that the first recorded case of nephrectomy for ruptured kidney was by the late Dr. Rawdon of Liverpool, on a boy of 12 years, who fell down steps, sustaining a bruise over the right ilium, when it was found that the kidney was almost completely torn across. He died later from cystitis due to attempts to remove the blood-clot from the bladder.[1]

A schoolboy, aged 12 years, was admitted to the Royal Infirmary, Liverpool, on the evening of July 20th, suffering from injuries caused by a fall. While returning to school after dinner in crossing a field he slipped on the wet grass and fell, his side coming into contact with the ground and (perhaps) a small stone. He was shortly afterwards picked up and carried home, being unable to walk, and seen by Dr. G. Gunn, of Neston, who found him in a state of collapse, with a frequent pulse and cold sweats. Vomiting set in and he was put to bed and kept warm. Later a couple of ounces of urine were passed, darkly stained with blood, and a diagnosis of "injury to the kidney" was made, and he was transferred to the infirmary by a motor, a distance of ten miles.

On admission at 9.45 P.M. he was conscious, absolutely blanched, bathed in a cold perspiration, pulse 108 per minute, small and weak, temperature 96·8° F., and respirations 28 per minute. The only injury apparent on examination was a small abrasion on the right side in the anterior axillary line, corresponding to the eighth, ninth, and tenth ribs, and about half an inch wide. There was no hæmorrhage from the skin nor sign of fractured ribs, and the abrasion was evidently caused by the stone. The abdomen, but more especially on the right side, was absolutely rigid and tender, and he complained of pain if touched there, the symptoms being most pronounced in the right hypochondrium. The right flank was absolutely dull on percussion, but there was no swelling or distension. He only complained of pain on being touched. There were no symptoms of renal or ureteral cramp, no ecchymosis at the root of the penis or over the external ring, and no testicular retraction. His condition was so serious that operation was deferred to see if there should be any improvement and ⅓th grain morphia was administered hypodermically, while he was packed round with hot bottles and blankets. He complained of severe thirst. At 12 P.M. he was sleeping. At 2 A.M. the pulse had risen to 120 per minute and the temperature to 100·6°. At 3.30 A.M. he was in a critical condition, with symptoms aggravated; and Mr. T. C. Litler Jones being called, decided on immediate operative interference.

[1] Vide THE LANCET, May 26th, 1883.

An anæsthetic (open ether) was administered and an incision was made 1 inch below and parallel to the twelfth rib through the muscles, and on cutting through the transversalis fascia the kidney was found buried in an enormous blood effusion invading the pelvis, diaphragm, and neighbouring organs. On turning out this clot the lower half of the kidney was found completely torn off and lying loose in the clot. (See figure.)



Reproduction of photograph of the specimen after removal.

The vessels attached to the upper portion were at once clamped and ligatured with Van Horn No. 1. catgut and the remainder of the kidney removed. The peritoneum covering it was found intact, and the blood effusion extending behind it over the diaphragm and down into the pelvis was removed as completely as possible, the cavity packed with dry sterile gauze, the muscle layers sutured with Van Horn catgut and the skin with silkworm gut, leaving an opening for the packs. He was then returned to bed, ⅓th grain of morphia was administered hypodermically and 4 oz. of salines hourly per rectum. The temperature and pulse-rate dropped immediately after the operation, but later steadily rose till 6 P.M., when they reached a maximum of 101·6° and 156 per minute. He was given small quantities of fluid by the mouth, and first passed urine (4 oz., deeply blood-stained) at 2 P.M. Morphia was again administered at 2 P.M. and at 7 P.M., and the saline continued hourly for 48 hours. The packs were removed 36 hours after operation, under gas, and the wounds repacked.

The after-history was uneventful. The wound healed without any sign of sepsis, and the boy quickly recovered his loss of blood; as the other kidney improved in tone more food was administered. He was discharged from hospital a month later apparently quite strong and well, and since then his progress has been good.

I would like to express my indebtedness to Mr. Litler Jones for permission to publish this case, and his kind assistance and advice on these notes.

Liverpool.

SALVARSAN IN SYPHILIS.

BY DUDLEY KENNARD, F.R.C.S. EDIN.,
HONORARY SURGEON, WESTMINSTER GENERAL DISPENSARY;
AND
W. HENRY GORDON, L.P.S.I., M.P.S.

WE have been using salvarsan, "606," in the treatment of syphilis for over a year, and we think that a short account of our experience may be of value. We have treated and followed up 200 cases which were in the primary, secondary, and tertiary stages.

A Wassermann reaction was always taken before commencing treatment, and again in six months, nine months, and a year. All cases under treatment have given a negative reaction, the reaction having been positive previous to the first injection. Two intravenous injections of salvarsan, "606," have been given in all primary and secondary cases, the injections being at an interval of three weeks, because if "606" injections are given at shorter periods there is great danger, as has been recorded in the French journals (Gaucher, Caravan, and others).

The urine has been examined daily in 20 cases, and this

has shown that arsenic is eliminated after intravenous injection for four days, and in cases of intramuscular injection arsenic is still present up to the twelfth day. Between the first and second injections of salvarsan the patients have been ordered a mercurial inunction, this being continued after the second injection for 20 days in each month for a period of six months. The preparation prescribed is "crème de mercure" (Gordon), as it is easily absorbed and is more cleanly than the official ointment.

None of the cases so treated has had a relapse or has shown symptoms of syphilis, but although at present their Wassermann reaction is negative it is impossible until further time has elapsed to regard them as cures.

We have had no serious accidents to report. In one case soon after the second injection there was an eruption of herpes round the chin and lips and on the tongue, which yielded to the ordinary treatment. Some of the cases presented slight induration at the site of the injection which soon disappeared.

In women we observed that the regular period following the injection appeared a week earlier than usual, and was sometimes profuse in character. In one patient with severe ulceration of the leg iritis occurred, but it was not due to the treatment. The dose administered has varied from 0·4 to 0·6 gramme, according to the condition of the patient.

The injections were done in three ways:—(1) *Subcutaneous.*—This method was quickly discarded as it proved too painful. (2) *Intramuscular.*—(*a*) In neutral solution; this method also proved painful and caused a good deal of induration. (*b*) In the form of an oily emulsion; this proved more satisfactory. (3) *Intravenous*—This method if properly performed is much the best way of administering salvarsan, except in those exceptional cases where it is impossible to find a suitable vein.

The apparatus we used in the intravenous method consisted of a glass cylinder of a capacity of 300 c.c. To this is attached indiarubber tubing fitted with two glass windows. The whole having been sterilised by boiling, a cannula and needle (previously sterilised in oil) are then attached. The apparatus having been filled with saline solution, it is impossible for air to enter at any time during the operation. The salvarsan solution must be prepared *immediately* before use and kept at a temperature approximating blood heat during administration. Chemically pure sodium chloride and caustic soda must be employed for the solutions. The technique is as follows.

Into a narrow-necked graduated glass cylinder of a capacity of 250 c.c., containing about 40 sterile glass beads, 40 c.c. of distilled water at a temperature of 104° F. are measured. The salvarsan, 0·6 gramme, is then gradually added, the tube being vigorously shaken to aid solution. The solution must not show (even when examined by transmitted light) any drop-like or gelatinous particles. To this are added 20 drops of a 15 per cent. caustic soda solution. A precipitate forms which redissolves on the addition of a few more drops of caustic soda solution. The clear yellow liquid is then filled up to 240 c.c. with a 0·5 per cent. saline solution prepared from sterile freshly distilled water. Each 40 c.c. of the solution now contain 0·1 gramme of salvarsan, 200 c.c. contain 0·5 gramme, so the dose required may be accurately ascertained.

An elastic band having been placed on the upper part of the arm the most prominent vein is selected at the bend of the elbow. The site of the puncture is then painted with iodine solution. The apparatus being filled with saline solution care must be taken that all air is expelled. The needle is then run into the vein, when blood will be seen to flow back by the glass window. The elastic bandage is then removed and the saline solution allowed to pass into the vein. If this takes place readily with no swelling at the site of the injection, the salvarsan solution is then slowly added to the saline until the required amount is given. Saline solution is again added until the liquid entering the vein is quite clear.

If swelling occurs at the site of injection it is caused by the needle having pierced the side of the vein; in that case it is advisable to remove the needle and select another vein. The presence of salvarsan solution in the tissues will cause painful induration and sloughing might occur. It may happen that the liquid does not flow freely, the point of the needle having come in contact with the wall of the vein; this is obviated by either raising or depressing the point of the needle.

There should be no local reaction. A general reaction nearly always occurs and varies in intensity according to the condition of the patient and the amount of salvarsan given. During the injection the cheeks generally become pink and some patients complain of a metallic taste in the mouth. An hour or two after the injection there is likely to be a rigor and the temperature may rise to 101°–102° F., with, perhaps, headache and vomiting. This condition quickly passes and the patient feels well soon afterwards. During the last few months we have observed that cases of vomiting have occurred less frequently. Whether this is due to an improvement in technique or the salvarsan supplied by Ehrlich being purer we cannot say. It is hoped by the particular combination of salvarsan and mercury to attain a means of preventing the development of tabes and paralysis.

There can be little doubt that Professor Ehrlich by his recent work has added a most valuable drug to our Pharmacopœia.

CLASSIFICATION IN GYNÆCOLOGY.[1]

BY W. E. FOTHERGILL, M.A., B.Sc., M.D. EDIN.,
HONORARY ASSISTANT GYNÆCOLOGICAL SURGEON, ROYAL INFIRMARY AND ST. MARY'S HOSPITALS, MANCHESTER; CLINICAL LECTURER IN GYNÆCOLOGY, UNIVERSITY OF MANCHESTER.

CLASSIFICATION marks the transition of any subject of inquiry from being a mere collection of observations and theories into being a science. In other words, no subject becomes a science until it is sufficiently well known to admit of the logical and orderly arrangement of its details. If this test be admitted, gynæcology is still a very young science, if, indeed, it has yet reached the scientific stage. As an art it has, of course, reached a high level.

The first attempts to give an orderly account of the diseases of women in this country seem to have been made in the later third of the nineteenth century. Thus the third edition of West's "Lectures," published in 1864, and the third edition of Grailey Hewitt's book, published in 1872, both contain traces of arrangement into diseases of the vulva, vagina, uterus and other organs. In 1877 Lawson Tait published a small book with a definite anatomical classification, and the same arrangement was used by Barnes, whose second edition appeared in 1878. From this date until the present time most books on the diseases of women have been arranged on the same plan, though some are conspicuously free from any attempt at logical classification. The object of the present paper is to examine the nature and results of this anatomical classification, and to find out if it is the best that can be made now, as it doubtless was when it came into use.

Though it may have been useful as a "preliminary effort," it is not only an artificial division, but a bad one of its kind, and it has been made worse by faulty application. For a number of conditions which are not conditions peculiar to women have been brought in. Such are the various skin diseases described under the headings "Vulva" and "Mons Veneris"; symptoms like pruritus, and affections of the bladder, urethra and rectum. Naturally the gynæcologist has to treat them; but when he is trying to give a scientific account of diseases of the female reproductive organs he might at least relegate other matters to an appendix. Conditions do not always appear in the appropriate anatomical division. Thus cystocele and rectocele are often called diseases of the vagina, prolapse and retroversion being placed amongst diseases of the uterus, while all four are really abnormalities of the pelvic connective tissue. These are all avoidable errors in the application of the system.

But the division itself is to blame for splitting up and multiplying diseases. Gonorrhœa, for example, is one condition; but in books it is described in different sections under vulva, urethra, vagina, cervix, uterus, tubes and ovaries. Thus facts which should be together are scattered abroad. Further, local pathological processes are made into separate diseases, and names are given to them such as

[1] A paper read before the North of England Obstetrical and Gynæcological Society on Feb. 17th, 1912.

vaginitis, endocervicitis, endometritis, metritis, parametritis, perimetritis, salpingitis, ovaritis. These are described, each with its symptoms, signs, diagnosis, prognosis and treatment. "It is a dull and obtuse mind," said Calvin, "that divides in order to distinguish; but it is a still worse which distinguishes in order to divide." The older gynæcological writers may not have distinguished between ovaritis and salpingitis with the conscious intention of dividing them, but their writings have effectively separated these processes in the minds of their followers. Nor can the use of the anatomical system be said to be successful in practice. Senior students and young graduates constantly remark that while they can make useful progress in medicine, surgery and midwifery, they are in despair about the diseases of women. Interest, intellect and industry are not wanting; the method is alone at fault. The subject presents no unique mystery. It is badly taught simply because writers and teachers persist in using the anatomical arrangement. How can the student grasp the connexion between vulvitis and salpingitis when they are separated by hundreds of pages in text-books and by the lapse of weeks in lecture-rooms? How can he help regarding ovaritis as a disease when it is described as one? How can he escape the conclusion that prolapse is a uterine trouble when it is placed among diseases of the uterus? Various other bases might be taken for the main divisions of a new system, but what is required is a natural arrangement.

The word "cancer" at once calls to mind a number of resemblances between all cases of cancer; but the term "disease of the uterus" does not suggest to the mind any resemblances between diseases of the uterus except that of place. The word "infective" conveys a number of facts concerning all cases of infection; but the word "vagina" tells nothing about any case of disease of the vagina except the site of the lesion. In short, the knowledge that a condition affects the broad ligament, the uterus or the ovary conveys much less information than the knowledge that the condition is an injury, a tumour or a malformation. In general terms, the important feature of a disease is not its site, but the way in which it departs from health—namely, its pathology. The word pathology must not be taken in its narrow sense of morbid anatomy, but must include function as well as structure, morbid processes as well as lesions. Does it not follow that the main divisions of any natural classification of diseases should be based on pathological resemblances and differences, minor features, such as the position of lesions, being used only in the subdivisions of the system?

Attempts to bring into use pathological main groups of diseases of women have been made in this country by four authors: David Berry Hart, J. W. Ballantyne, W. Blair Bell, and the present writer. In 1893 Hart read a paper to the Edinburgh Obstetrical Society on the Pathological Classification of the Diseases of Women, with a Plea for the Revision of Current Views.[2] He suggested 11 headings as follows: (1) Congestive (vascular ruptures included); (2) Hypertrophy; (3) Atrophy; (4) Traumatism; (5) Simple Inflammations; (6) Micro-organismal (includes pathological versions); (7) Herniæ (prolapse, &c.); (8) New Growths; (9) Displacements (inversion only); (10) Developmental Errors; and (11) Neuroses.

Ballantyne published his "Essentials of Gynæcology" in 1905. His classification of the diseases of women was in 10 headings. He put hypertrophic and atrophic states together, although they are opposite in nature. He included extra-uterine pregnancy, which is midwifery; and also sterility and menstrual anomalies, which are symptoms rather than primary conditions. Hart and Ballantyne both include "neuroses," which would generally be regarded as disorders of the nervous system, rather than of the female reproductive organs.

In his "Principles of Gynæcology," published in 1910, Dr. Blair Bell also uses ten headings. One of these is "Disorders of the Normal Physiological Conditions in Relation to Menstruation," and this, like Ballantyne's "Menstrual Anomalies," deals with symptoms, not with primary conditions. Another heading is "Disorders of the Normal Conditions in Relation to Conception," which, again, is midwifery. Various conditions which are not primary disorders of the female reproductive organs are included under the heading, "Allied Morbid Conditions."

Thus Ballantyne's and Blair Bell's arrangements are not faithful to their main basis of division, and they poach on obstetrical ground. Hart's plan, if the heading "neuroses" be omitted, is free from these defects; but it suffers with the others from the fact that the student cannot easily keep in mental view so many as ten groups of conditions.

For some years I have been using six main divisions both in clinical teaching and in my own systematic work.[3] They were suggested by the arrangement of specimens introduced by Professor Lorrain Smith into the pathological museum of the University of Manchester, and thus have the sanction of professional pathologists. They are: (1) Developmental Errors; (2) Vascular Changes; (3) Mechanical Conditions; (4) Results of Infection; (5) Progressive Conditions; and (6) Retrogressive Conditions.

1. "Developmental Errors" must, for gynæcological purposes, contain two sub-groups: (*a*) congenital errors; and (*b*) errors in development at puberty, for the reproductive organs have two phases of development, one embryonic and fœtal, the other occupying the years immediately preceding and following puberty.

2. "Vascular Changes" includes active and passive hyperæmia as recognised at first by symptoms and later by hypertrophy and fibrosis respectively. This group also includes varicosity of the veins in the pelvis and hæmorrhage into the pelvic organs, the pelvic cellular tissue, and the peritoneal cavity.

3. "Mechanical Lesions" is a large and obvious group containing injuries, displacements, and herniæ.

4. "Results of Infection" is a main division which should be subdivided according to the organisms present in each case. In this group the few cases of primary pelvic parasitic disease may be included without gross impropriety.

5. "Progressive Conditions" includes overgrowths, cysts and new growths. Perhaps this group should be divided. But it is hard to draw the line between hypertrophy and adenoma of the endometrium or between innocent and malignant new growths.

6. "Retrogressive Conditions" occur mainly in connexion with the menopause, but the reproductive organs share in the general changes of senility.

Further, there are errors in the retrogressive changes which are characteristic of normal menstruation, ovulation and involution. I have found that the use of these main groups has certain advantages. The division is logical and is based on the most important resemblances and differences between morbid conditions—namely, the pathological. It is familiar to students of medicine, and the headings are so few that they can easily be remembered. If the student is able to place a case in one of these groups, he has made a definite step towards a complete diagnosis and has gained some useful information about the patient. But it is, of course, a division of conditions, not of patients, for a woman can have two or more conditions at the same time (infection and new growth, for example).

Such a division has the further advantage that it does not magnify symptoms and pathological processes into diseases. Nor does it lead to confusion between primary conditions affecting the reproductive organs and general diseases such as phthisis, rickets, anæmia, and myxœdema, which often lead to the appearance of gynæcological symptoms. Such symptoms of general diseases may well, like diseases of the female bladder, urethra, and rectum, be mentioned by the gynæcologist in teaching; but it is better that they should be kept out of any classification of diseases of the female reproductive organs which aims at being scientific and logical.

Those who have written text-books and arranged courses of lectures according to the anatomical plan can hardly be expected to approve of the changes now advocated, though the use of pathological main groups saves much space and prevents much repetition. Again, students taught to use a pathological main division, unless well informed and agile in mind, might easily fail to please examiners of the anatomical generation. Thus mental inertia and the fear of the examiner tend to perpetuate the anatomical grouping. But it cannot last much longer, and the writer hopes to see the day when it will not be used in any course of lectures delivered in this country nor in any book which holds a place on the British market.

THE SEX OF THE LARVÆ OF MOSQUITOES
AND OTHER EXPERIMENTAL WORK.

BY H. A. ADIE.

(From the Malaria Laboratory at Lahore.)

THOSE interested in medical entomology have not been able, in spite of the large amount of work done on anophelines alone, to distinguish male from female larvæ in the case of mosquitoes. Working with anophelines I have succeeded in solving this difficulty.

On each side of the sixth abdominal segment of the anopheline larva can be made out, in males, a brownish oval tumidity. This can be seen with a two-thirds or a hand lens; with practice the latter is sufficient for a fair-sized larva. With a two-thirds it can be recognised on the third day. The brownish oval tumidity is the pear-shaped testis with its hard sac. On dissection it is found to be connected by a vas with a vesicula and ductus. It contains spermatozoa both formed and undeveloped. This test decides the question of the male sex. Twenty-four prognostications have come out correct on completion of metamorphosis. On dissection ovaries and spermatheca are quite clear in the female pupa, and in the case of the female larva rudimentary ovaries can be seen.

In the culex larva the testis has not the conspicuous brown colour or the hard sac, and therefore is not so recognisable.

The question has arisen, Are M. culicifacies and M. listoni distinct species or races? It is known that in some localities—e.g., Punjab plains—pure culicifacies is very common, and pure listoni only met with occasionally (Gujrat and Amritsar). In other localities, such as the Kangra and Kulu Valleys, pure listoni is very common and culicifacies a curiosity. The higher valley (Kulu) has no culicifacies. Where both are met with, as in the lower parts of the Kangra Valley, forms were obtained which diverged from their type markings, and it was sometimes difficult, if not impossible, to say to which species a particular specimen belonged. James and Liston, in their standard work on Indian anophelines, recognise this. "Indeed, it would seem that in a few places (e.g., Bombay) the prevailing variety is almost exactly intermediate between the two species." Both breed in running water and are malaria carriers, but there are some small differences in the larval characters, and in the resting attitude of the adults. In this connexion reference might be made to the African malaria carrier, M. funesta, which closely follows the description of the above two species.

From the ova of the adult listoni from the Kangra Valley and adult culicifacies from Ferozepore male and female imagines were bred out. Then from the hatched-out insects males and females of culicifacies and listoni were kept with females and males of listoni and culicifacies under as suitable conditions as possible in the cold weather. It might be pointed out that the necessary arrangements for artificial temperatures, feeding, and watching generally, required the strictest attention day and night. The mean temperature in Lahore at the time was about 55° F.

About 17 days after pairing a female culicifacies, which had been kept in a jar with a male listoni, was found to have died during the night. She was immediately dissected and seen to contain ova of apparently full size but less than the usual number. As far as could be made out they had the characters of culicifacies ova. The spermatheca did not show spermatozoa. The coming-on follicles were at figure 4 of Christophers's scale.

On Dec. 29th, 26 days after pairing, a female listoni, which had been kept in a jar with two male culicifacies in succession, was accidently killed and immediately dissected. She had less than the full number of apparently full grown ova, and concerning these a most interesting point was observed—viz., while the majority of the ova were of the listoni type, the upper surface having two fringed oval areas, a few were of the culicifacies type, the upper surface being one continuous fringed area; also one intermediate form was observed. In this case as well the spermatozoa could not be recognised. The coming-on follicles were at figure 4, Christophers's scale.

In a third experiment, male listoni and female culicifacies, the female after 22 days was found sprawled and dissected. She had only about 30 ova of culicifacies character, and not full size, but floats were present. The spermatheca was apparently empty.

Of course, it was unfortunate that the eggs could not be hatched out, but other experiments are in progress. The presumption of mating is probable, especially from the evidence of the ova in the second experiment.

The objections still outstanding are the apparent absence of spermatozoa from the spermatheca, and the possibility of parthenogenesis. In the consideration of the former objection I might point out that it has often been the experience in routine dissections in this laboratory to find, in the case of insects bred in captivity, less than the full number of ova and no spermatozoa. As regards the latter objection, so far as dissections of anophelines here have shown, we have not found egg formation in virgins.

Lahore.

ABSCESS OF THE LUNG AND LIVER:
SIMPLE CURE OF A CHRONIC CASE BY THE UPSIDE-DOWN POSITION.

BY W. E. MCKECHNIE, M.B., CH.B. EDIN.,
MAJOR, INDIAN MEDICAL SERVICE.

THE following case is recorded to show how a serious and dangerous condition of long standing may be cured by very simple means.

A boy of 14 had coughed up pus day and night for five years. He had had some acute illness previous to the establishment of this condition. When I saw him he was stunted in growth and much smaller than his younger brother, having grown very little since the beginning of his illness five years previously. The parents had given up hope of cure, as he had undergone much treatment without any benefit. The amount of pus coughed up in 24 hours averaged about a teacupful. It was of creamy consistency and varied in colour from a brownish-liver colour to a darkish yellow; it had only a faint smell. On physical examination the base of the right lung was dull, the dulness being continuous with that of the dome of the liver; breath sounds were nearly absent, but moist râles were heard higher up; the diaphragm moved only slightly on the affected side.

From the character of the pus, the practically aseptic condition, and the physical signs, I diagnosed liver abscess with perforation of diaphragm and pleura and secondary abscess in the base of the lung, with adhesion of lung, liver, and pleura to the diaphragm in the neighbourhood of the perforation; with intermittent partial evacuation of the cavities in the liver and lung *viâ* the bronchi and trachea. Fig. 1 shows the condition diagnosed, and it is evident that

FIG. 1.

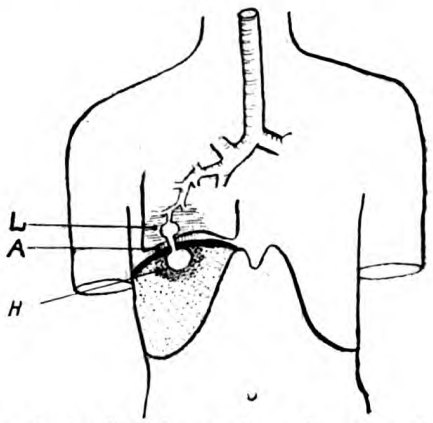

Diagram showing site of abscess cavity. L, Lung surrounding abscess. A, Adhesions between pleura and diaphragm. H, Liver surrounding abscess, adherent to diaphragm.

if such was truly the actual condition there could be little hope of such cavities healing under ordinary circumstances, as the force of gravity would prevent complete evacuation of so complicated a cavity at such a hydrostatic depth by the simple act of coughing, especially if the diaphragm were anchored to the lung and liver so as to diminish its squeezing

expulsive force. It appeared then that the cavities were only partially emptied by fits of coughing when, after filling up, the pus began to rise in the bronchi, causing irritation by its hydrostatic pressure on the lung and liver and its presence in the healthy parts of the bronchi. That this surmise was probably correct was shown by the fact that when I began treatment by inverting the patient at once a very large quantity of pus was evacuated, a full breakfast cupful—a quantity greater by far than he had been in the habit of evacuating by any one spasm of coughing.

Acting on these beliefs my treatment was simplicity itself. I made the boy hang suspended over the edge of a table, head downwards, the whole body hanging vertically upside down, the legs and thighs lying on the table at right angles to the body and thus supporting him. The position is shown in Fig. 2. In this position he was made to cough and squeeze

FIG. 2.

Postural drainage.

his chest till no more pus came out. By this means the abscess cavity was completely emptied, and he was made to repeat the process five or six times a day. At first he got rid of large quantities of pus, but it rapidly diminished, and in about six weeks he ceased to have pus and was cured. His progress was remarkable. The whole boy altered, and a year afterwards he had grown several inches and caught up his younger brother. He became active, bright, and cheerful, and was able to do his lessons with ease, instead of being very backward as he had been before. I think this is a good example of a simple application of the principle that we should allow the force of gravity to drain abscesses. This simple procedure cured in six weeks, without operation or pain, a condition which had lasted five years, had baffled other modes of treatment, threatened the life of the patient, made it a misery, and prevented his growth. No other treatment was employed by me.

I suggest that this postural method of treatment should be tried in abscess of the lung and bronchiectasis before resorting to the more formidable surgical procedures.

PULMONARY EMBOLISM AS A SEQUEL OF DIPHTHERIA.

BY D. STEWART, M.B. GLASG., D.P.H. CAMB.,
LATE MEDICAL SUPERINTENDENT, MIDDLE WARD HOSPITAL, MOTHERWELL.

PULMONARY embolism has been so rarely recorded as a sequel of diphtheria that the following notes of a case which was under my observation in the Middle Ward Hospital, Motherwell, may be interesting.

A female, aged 4, was admitted to hospital with mild faucial diphtheria, and progressed favourably till after a fortnight's residence in hospital, when she became moderately feverish, very restless, and with signs and symptoms pointing to pulmonary trouble. Alteration of the respiratory murmur was made out over the right upper lobe, though from the increasing restlessness examination was difficult. Pneumonia was provisionally diagnosed, but the child grew very rapidly worse, with increasing lividity, restlessness, and respiratory embarrassment. Death took place within 24 hours of the first appearance of symptoms.

Noteworthy points in the case were the mildness of the primary angina and the suddenness of the onset of the fatal sequel—the pulse-rate rising from 108 to 140, and the respiratory rate from 24 to 40 in an hour. Also the temperature was not raised proportionately to the pulse and respiration rates. These points and the quick fatal issue combined to make me doubt the accuracy of the provisional diagnosis, especially as thorough auscultation had been impossible. Permission for a post-mortem examination was obtained, and a large infarction implicating the upper right lobe was found. Some dilatation of the right side of the heart was present but no gross valvular lesion.

Ransome and Corner in an article in THE LANCET of Jan. 14th, 1911, p. 94, reviewed nine recorded cases of gangrene of limbs during convalescence from diphtheria. In one of these cases, recorded by Poupon,[1] embolus in the popliteal artery was revealed by the necropsy and pulmonary embolism was diagnosed during life, but permission was not given to examine the lungs at the necropsy.

Cerebral embolism secondary to endocarditis of the left side of the heart and causing hemiplegia has been recorded fairly often in diphtheria (69 cases in literature according to Rolleston, *Practitioner*, January, 1909, p. 114), but pulmonary embolism resulting from right-sided endocarditis is rarely heard of in this connexion.

ROYAL SOCIETY OF MEDICINE

CLINICAL SECTION.

Electrocardiograms.

A SPECIAL meeting of this section was held on March 20th, Dr. SAMUEL WEST, Vice-President, being in the chair.

Professor EINTHOVEN (Leyden) gave a demonstration based on Observations of the Movements of the Heart by Means of Electrocardiograms. This was illustrated by lantern slides of the records of actual cases. He pointed out that muscular contraction and action current are dissimilar, but related to one another. Contraction is a mechanical action, but action current an electrical phenomenon. Electrocardiograms showed that the pulse is an imperfect guide to cardiac action. Differences in magnitude of the pulse do not necessarily correspond to differences in the strength of the contractions of the heart. The ventricles might contract forcibly, and yet a feeble or no pulse be produced by that contraction, because at the time the left ventricle is insufficiently full. This is the case when the ventricular contraction is not preceded by a contraction of the auricles. It could be shown also that in auricular fibrillation the irregularity of the pulse is not caused by irregularity of the ventricular systoles, but by irregularity of those of the auricles. The *pulsus alternans*, in which every second beat is small and feeble, is probably explained by slight changes in the strength of the ventricular contractions. A negative auricular effect, as shown on the electrocardiogram, is probably quite as valuable as a positive one. Tachycardia may exist, and be demonstrable by the electrocardiogram, but the pulse may not be rapid. The work of the heart cannot be judged by the pulse. By experiments on dogs, by which he had estimated the ventricular pressure, he had shown that this is related more closely to the electrocardiograms obtained than to the state of the pulse. The differences in the degree of contraction of the heart may be small, while the differences in the size of the pulse may be very great. It is possible to judge the condition of the heart muscle with greater accuracy by means of the electrocardiogram than by pressure curves obtained from the pulse.

Dr. FLORENCE BUCHANAN gave a demonstration on certain experimental observations which she had made on the heart movements of hibernating animals by means of electrocardiograms. In 11 dormice she had found that during awakening from hibernation there was dissociation of the auricular and ventricular contractions. When the animal was very torpid, showing no signs of respiratory movements for several consecutive minutes and having a pulse-frequency of from 12 to 30 a minute, the records showed only ventricular effects recurring at irregular intervals, the more irregular the lower their frequency. Apparently when the

[1] Le Progrès Médical, vol. clxiii., p. 100.

animal was in its deepest sleep only the ventricles were beating. When the ventricular frequency increased to 40 per minute auricular extra-systoles started, appearing at long irregular intervals, and each well marked and of long duration. These gradually increased in frequency and became more regular, and usually by the time the ventricular systoles had reached 100 per minute the auricular extra-systoles were equally frequent. At the time during which the auricular effects were overtaking those of the ventricles the ventricular effects were apt to become irregular, one or more being dropped, giving records like those of complete heart-block produced by vagus stimulation in other mammals. These auricular extra-systoles did not influence ventricular frequency. True auricular systoles only became visible as the season advanced, or perhaps as the number of times the animal was roused from hibernation increased. They had never occurred while the ventricular frequency was less than 58 per minute. At first they did not always regularly precede each ventricular systole. Experiments on bats served to show that evidence of heart-block, complete or incomplete, was likely to be forthcoming in those animals during hibernation.

Dr. JAMES MACKENZIE said that electrocardiograms had afforded an admirable means of accurate diagnosis in cardiac disease, and had led to great advances in our knowledge of many obscure affections of the heart. Some years ago he had attempted to explain certain forms of arrhythmia by ascribing them to contractions starting in unusual positions, and it had been very gratifying to him when Dr. Lewis had demonstrated by electrocardiograms that the auricle in such cases had gone into fibrillation. This method had also explained some cases of tachycardia, when the auricles were beating faster than the ventricles. It had helped with regard to the management and treatment of patients. He regarded the *pulsus alternans* as a condition which is not rare but always of very grave significance.

Dr. THOMAS LEWIS paid a high tribute to Professor Einthoven's work. He said that the profession was indebted to Professor Einthoven for a perfected instrument and for a method of unrivalled precision. First upon the list of their indebtedness to this instrument he would place the almost universal corroboration it had given to the findings by another method which was also new and was devised by Dr. James Mackenzie. The importance of this corroboration could scarcely be exaggerated, for the method to which he referred—the analysis of venous pulse curves—was one which could be applied by all who practised medicine. He illustrated his contention by reference to the interpretation of such irregularities of the heart's action as were produced by premature contractions or extra-systoles and by heart-block. The analysis of cardiac irregularities was a chapter of medicine fast reaching its close. It was but rarely that the galvanometer failed to disclose the nature of a disordered heart action. In the majority of instances its answer was immediate and decisive. Of cardiac irregularities one had been spoken of by Dr. Mackenzie, which, on account of its frequency and its important influence upon the life-history of the patient, had commanded close attention. He referred to auricular fibrillation. Among the first electrocardiograms of auricular fibrillation were those taken by Professor Einthoven, and it was his instrument which introduced us to auricular fibrillation as a clinical phenomenon. We were indebted to this galvanometer for our knowledge of the site of origin of the heart beat. It had shown us that in pathological states other centres of impulse formation were active in the muscle, and it had located these centres in a remarkable fashion. It was possible to-day to state, not only that a new impulse arose in auricle or ventricle, but, within certain limits, the part of the individual chamber in which the impulse had its birth could be defined. The new method had very materially advanced our knowledge of paroxysmal tachycardia; it had shown us that those crises arise, not as the result of simple disturbances of innervation, but as an outcome of new and rhythmic impulse formation in portions of the heart remote from the pacemaker. It had transpired that the galvanometer could detect not only functional disturbances of the main auriculo-ventricular bundle, but also similar defects in the main branches of it. This was a discovery of fundamental importance in the study of heart affections. In his original paper Professor Einthoven had pointed out certain relations between electrocardiographic curves and right- and left-sided ventricular hypertrophy. A great deal of evidence was now forthcoming in support of his original contention that the relative weights of the two ventricles could be estimated by this means. It would be needless for him to emphasise the importance of these observations. The examples he had given would suffice to illustrate the unquestionable and far-reaching value of the method. Electrocardiography was a growing science. Instruments were being installed in all lands where pathology and clinical medicine were actually studied. The value of the method had received immediate and universal recognition. Curves were shown to illustrate the various points.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Exhibition of Specimens.—Extra-peritoneal Dermoid Cyst.—Cæsarean Section in a Case of Dystocia.—Pathological Classification of the Diseases of Women.

A MEETING of this section was held on March 7th, Dr. AMAND ROUTH, the President, being in the chair.

The following specimens were shown:—

Dr. H. A. LEDIARD (Carlisle): (1) Sacral Teratoma in an Infant two days old—Operation and Recovery; and (2) Large Warty Fibroma of the Labium.

Dr. H. BRIGGS (Liverpool): (1) Fibroid of Uterus of Unusual Character; and (2) Large Placenta in a case of Ectopic Gestation Three Months beyond Term.

Dr. CLIFFORD WHITE: Fœtus with Congenital Hereditary Graves's Disease.

Dr. C. HUBERT ROBERTS: (1) Demonstrations under the Epidiascope of a Three Months' Abortion, the Placenta undergoing marked Calcareous Degeneration; and (2) Sections of Ovarian Concretions (Hæmatoliths) and of the cyst wall in which they were contained.

Dr. LEDIARD read a short communication on a case o Extra-peritoneal Dermoid Cyst, which had suppurated, occurring in a patient, aged 26. who was operated upon in 1906. The tumour was of the size of a six months pregnancy and had been felt for four months. The peritoneum was raised by the growth, and incision of the abdomen revealed a silvery-surfaced tumour. The cyst contained sterile pus to the extent of two pints. Traction and finger dissection sufficed to extract the cyst without damage to the ureter or other organs. The cyst was thick-walled for the most part, and contained four teeth, nodules of cartilage, and some hairs. The patient made an easy recovery and was at present in good health—i.e., six years after operation.

Dr. HENRY BRIGGS read a short communication on Cæsarean Section in a case of Dystocia due to Loops of Cord round Fœtus at Term. He remarked that a short umbilical cord, whether absolutely short or relatively short, by being coiled round the fœtus may arrest descent and prevent engagement of the head in the pelvic brim. Such extreme cases were very rare. In Dr. Briggs's case the patient, a young woman aged 22, was admitted to the Liverpool Maternity Hospital at the full term of her third pregnancy at 10.30 A.M. on Jan. 28th, 1912. Labour had been in progress 10½ hours, and the cervix admitted the finger. Pains were slight. On the following day the membranes ruptured spontaneously, and at midday the cervix was half dilated. At 11 P.M. the same day the cervix was still incompletely dilated and the head was still above the brim. The general condition of the patient remained good, violent expulsive pains being relieved by an injection of scopolamine and morphine. The patient was first seen by Dr. Briggs after she had been 43 hours in labour, and up to the completion of the fifty-second hour the conditions seemed consistent with the birth of a living child when the cervix was fully dilated and the head engaged. After the patient had been 52 hours in labour she was examined under an anæsthetic, and the fœtal head palpated with the hand in the vagina. The sagittal suture lay nearer the pubes (Leitzmann's obliquity); the disengaged head receded readily above the brim, as if its ascent were easier than its descent; the manipulation of the head elicited the sensation of its being held from above, and the head persisted in lying transversely high up and inaccessible. The fœtal heart was beating normally. The obstruction within the uterus was beyond any safe method of attack from below. Patience in awaiting natural efforts had been adequate, if not excessive. It was therefore decided to effect delivery of the child by Cæsarean section. It was then found that there were three complete collar-like, and appreciably tight, coils round the

neck. From the navel to the neck the cord passed under the right shoulder and across the back of the chest and over the left shoulder. The pallor of the child when first delivered was alarming. After loosening the coils of cord the child began to breathe, and was still thriving. Dr. Briggs was of opinion that delivery by forceps or version would have been difficult, if not impracticable, and that the life of the child entirely rested upon the treatment by Cæsarean section.

Dr. W. E. FOTHERGILL read a short communication entitled "A Plea for the Use of Pathological Classification of the Diseases of Women."

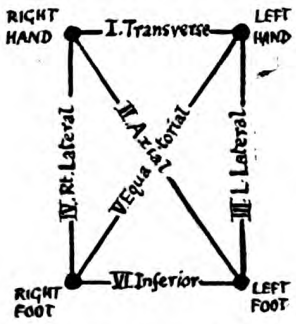
CHELSEA CLINICAL SOCIETY.

The Human Electrocardiogram.

THE annual clinical debate of this society, dealing with Disorders of the Circulatory System,[1] was continued on March 19th at the Physiological Laboratory of the University of London, South Kensington, Dr. MANSELL MOULLIN being in the chair.

Professor WILHELM EINTHOVEN, of Leyden, read a paper on the Various Forms of the Human Electrocardiogram, which will be found fully illustrated in this issue of THE LANCET.

The discussion was commenced by Professor A. D. WALLER, who said: It has been a great pleasure to all of us, and to me especially so, to listen to Professor Einthoven's lucid description of his state of mind and knowledge in this matter of the electrocardiogram. We all know the great share that he has taken in the development of our knowledge of this subject, and how his beautiful instrument, the string galvanometer (I wish it had a more beautiful name), has transformed the electrocardiogram of the laboratory into a common object of the hospital, where it is called to play its part among the time-honoured methods of clinical diagnosis. Like all new methods it has its detractors who know too little, and its zealous advocates who say too much. But in spite of both kinds of extremists I think this method will render real service to clinical medicine; indeed, as you have just heard, it has already done so. Obviously, time will not allow me to consider all the developments that have entered into Professor Einthoven's exposition. But I should like to take advantage of his visit to clear up a difference between us as regards the relative effectiveness of the several possible leads from the heart by means of the hands and feet. There are six such leads—viz.,[2] I, transverse; II, axial; III, left lateral; IV, right lateral; V, equatorial; and VI, inferior—summarised diagrammatically in the schema shown. In my first description of 1887 I classified



these six leads into two groups of three, "favourable" and "unfavourable," according as the electrical pulse was large or small. Obviously in a first survey of the matter, when the task before me was to demonstrate the physiological origin of these various derivation effects, it was necessary to review all of these six cases. But at a later stage, the facts and their common principle having been established, it became possible and necessary to simplify the six original premises. Professor Einthoven, proceeding from the observed fact that the difference in case VI (inferior) is very small, and that there is accordingly a very small difference between III and V and between II and IV, treats that difference as negligible, and reduces the experimental cases from six to three by treating the two lower limbs as equipotential. In this way, regarding the two lower limbs as one limb, he eliminates cases VI, IV, and V, leaving cases I, II, and III, which afford three cardinal magnitudes from which he calculates the position of the heart. This simplified scheme may be represented by a triangle thus, or thus, and for purposes of calculation as well as for clinical investigation is obviously convenient, although it does not take into account the small difference of potential between right and left foot.[3] In Einthoven's first account of the matter in 1895[4] he agreed with me in every particular, but a few years later, in 1908[5] he demurred to my reckoning the left lateral—i.e., III—as an "unfavourable" lead. He selects it as one of the three positions I, II, and III, and presents as a law that the magnitudes II − I = III, or I + III = II—i.e., he decomposes the axial difference of potential into its transverse and longitudinal components. I accept this mode of stating the case as being theoretically correct, but I also adhere to my own statement of "favourable" and "unfavourable" combinations, reckoning the left lateral with the latter. In the great majority of normal cases I have found the left lateral III much smaller than the right lateral IV, and the equatorial V much smaller than the axial II. Otherwise stated, I present in accordance with my diagram of 1887 the left hand in combination with either foot as the "bad hand," and the right hand as the "good hand." The two unfavourable cases, left lateral and equatorial, are approximately equal and of smaller magnitude than the two favourable cases, right lateral and axial, which likewise are approximately equal. It is hardly necessary to add that VI, the inferior, is smaller than any other. Einthoven gives the following example of his equation—the numbers express voltages of R:—II (0·0013) − I (0·0009) = III (0·0004). Obviously in this case the left lateral III was much smaller than either the transverse I or the axial II. My own numbers, obtained this year (1912), as well as the first tentative numbers of 1887–90. are of a similar order. They bear out my first statement as to the favourable and unfavourable trio in 1887–90, and bear out the statement contained in Professor Einthoven's trio. Thus in the subject now under observation the values of R in Einthoven's trio are:—I (0·0010), II (0·0014), III (0·0004). Cases are indeed to be met with in which this first ventricular spike (R or QRS) is larger in III than in I; others in which it is negative instead of positive, and if time permitted I should have an explanation to offer of this which would further justify my placing case III in the unfavourable group. Einthoven has said that I probably did so from having mistaken T for R—i.e., a second for a first ventricular wave. But I can assure him that there was never the smallest risk of my falling into this error—the double ventricular movement was clear to me from my very first observations; what troubled me at that time with the capillary electrometer was the *direction* of the first phase, which sometimes appeared to be positive, sometimes negative. Thanks to his "string galvanometer" this has been cleared up; we see readily enough on the records that the first phase is sometimes positive, sometimes positive-negative, sometimes negative, and that this is especially the case in left lateral records (III). Lead III is, I believe, Professor Einthoven's favourite lead, and it is also mine, for the reason that it is a borderland case and the most variable in form of all the six normal cases. And it is the case of most importance to study

[1] THE LANCET, March 23rd, 1912, p. 795.

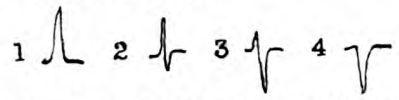
[2] I take the order as above in order that my numbers I, II, III should correspond with Professor Einthoven's I, II, III. Otherwise I should have preferred to make the right lateral III and the left lateral IV.

[3] This difference varies with the conditions of derivation of the heart—variations of the surface of contact with the diaphragm—state of the lungs, stomach, and liver. Sometimes it is too small to be estimated numerically. Sometimes it (i.e, V_I or R) amounts to a tenth of the value found for the transverse effect

[4] Pflüger's Archiv, vol. lx.

[5] Ibid., vol. cxxii., p. 552

under normal conditions as a preliminary to the study of pathological records. The first ventricular wave (Einthoven's wave *R* or *QRS*) in lead III presents the following varieties of form in various normal subjects—



and with a rather slow-moving string this last form may appear, i.e., purely negative, in striking contrast to the first form in which it is purely positive. I do not stop for any explanation, but go on to say that clinically this apparently negative response of the left lateral position has been given as characterising (1) cardiac neurasthenia; (2) hypertrophy of the left heart; and (3) a lesion of the right limb of the auriculo-ventricular bundle of Kent and His. Now it may mean any or all of these lesions—that is not for me to say; I only enter a caveat against concluding too hastily what it means, since it commonly presents itself in perfectly normal subjects. Of half a dozen random cases recently tested in this laboratory, three present it and three do not. And I am convinced that those three first cases are not cases of cardiac neurasthenia, or aortic disease, or lesion on the right limb of the *a.-v.* bundle, and I know that at least one of the three persons who do not present it has well-marked hypertrophy of the left side. I have learned to recognise when to expect this pronounced negative effect; it occurs in any case where the transverse is larger than the axial effect; it does not occur when the transverse is smaller than the axial effect, and I think that Professor Einthoven will be disposed to recognise in this an illustration of his normal equation I + III = II. I do not forget that this is a *clinical* meeting in a physiological laboratory; I have therefore confined my remarks to a particular physiological item—the varying character of the first ventricular wave *R* in lead III—because its consideration strikingly illustrates the necessity of a physiological basis as a preliminary to clinical judgment. I shall not trespass upon the clinical domain, which is to be dealt with by other speakers, Dr. Lewis, Dr. S. R Wells, Dr. Halls Dally, who have special knowledge of special aspects of this manifold problem viewed from the clinical side. I have been particularly gratified by the presence here to-day of Dr. Thomas Lewis. I have not forgotten the zeal and ability with which he first addressed himself to Einthoven's string galvanometer in this laboratory, and the acumen with which he has followed it up in the hospital. The extension of the method as a clinical method will have been principally due to the enthusiasm of Dr. Lewis, and to the special clinique which he conducts at the University College Hospital. Auricular fibrillation, or, as I should have preferred to hear it called, auricular asystole, as everyone knows, thanks to Dr. Lewis, is now as familiar on the human subject in hospital as it is upon animals in the laboratory.

Dr. THOMAS LEWIS said that it had been a peculiar pleasure to him to have seen and heard Professor Einthoven expounding his methods and his views to an audience of his countrymen. Professor Einthoven had given them a splendid address, and had provided them with much food for reflection. Continuous advance in knowledge was slow; the chief progress was in steps, and a step was the result of the introduction and application of a new method. Einthoven was one of those rare workers who had devised such a method. He wished to speak more especially of the assistance which the new method had given to students of disordered heart action. In the study of arrhythmia it had proved invaluable, so much so that this chapter of clinical medicine was rapidly closing. It was only in the rarest instances that the galvanometer failed to provide an exact analysis of the sequence of cardiac chamber contraction. Professor Waller had uttered certain warnings in regard to the value of the method in the examination of hearts which beat regularly, and had especially criticised conclusions which dealt with the variations in the shape of the ventricular complex. He concurred with Professor Waller, in that he fully recognised the necessity of a full study of the normal electrocardiogram before dogmatic assertion in respect of the abnormal curves could be justified. Rash statements had undoubtedly been made, but not by clinicians working in this country. Nevertheless, and after a close study of the subject which had lasted for four years, he could speak with confidence of the value of electrocardiograms taken from patients with regularly beating hearts. Supposing that the limits of the several peaks and depressions were ascertained in a series of 50 or more subjects, and supposing that in a patient who presented no other signs of cardiac trouble these limits were surpassed in three, four, or more directions, it could be confidently asserted that the heart was abnormal, and that it was abnormal was borne out by his clinical experience. He referred to the curves which were held to represent damage of one or other branch of the auriculo-ventricular bundle, of which Professor Waller had also spoken. He maintained that the evidence which associated these curious curves and the corresponding lesion was considerable. If the right branch of the bundle was destroyed the impulse would travel to the left and apical portions of the ventricle and give rise to a curve similar in outline to that of a premature contraction arising in this region. That might be considered all very well in theory, but it had been proved experimentally, and in cases in which the lesion had been diagnosed before death, such lesion had been found post mortem. Dr. Lewis emphasised the frequency of this sign and the importance of its association with widening of the *P–R* interval; for the two together were evidence of a widely diffused muscle damage, which probably affected not only the main bundle and its branches but also more silent areas of the heart; a parallel was drawn between the condition and the similar nervous phenomena in disseminated sclerosis. A prominent physician, speaking but a little while ago at a large London hospital, a physician who weighed his words before he uttered them, declared that an examination of the heart was incomplete to-day until the electrocardiographic examination had been undertaken. Dr. Lewis actively supported this view. The fame of Einthoven's method had spread to all parts of the world. Instruments were installed, or were being installed, at several London hospitals. There were a number in New York, and many in Germany and other countries. He looked forward to the day when Einthoven's instrument would be a part of the equipment of all large hospitals, and had no doubt that the time when this would happen was fast approaching. In conclusion, Dr. Lewis thanked Professor Waller for his kind references to his own work at University College Hospital, and for the cordial manner in which he had expressed his appreciation of the new clinical method.

Dr. J. F. HALLS DALLY made a few remarks upon the case of Adams-Stokes syndrome to which reference had been already made. The case was that of a man, aged 64, first seen in the out-patient department on May 4th, 1911. There was no history of rheumatism or of any acute specific infection. Syphilis was denied, and a Wassermann reaction proved negative. The patient was a moderate smoker and drinker. During the previous year he had occasional attacks of giddiness apart from exertion, with brief periods of unconsciousness once or twice a week, preceded by dimness of vision. These syncopal attacks had become more frequent, and were followed by dyspnœa lasting for about a minute; there was no headache or pain in the chest, but palpitation, exhaustion, and shortness of breath, together with slight cough and expectoration, were his chief symptoms. On examination the man appeared older than his years. A well-marked arcus senilis was present in both eyes. The brachial and radial arteries were thickened and tortuous, but not the temporals. The blood pressure (Pachon) registered 210 mm. Hg in systole, 105 mm. Hg in diastole. He had an apical systolic murmur communicated to the anterior axillary fold; there was some œdema of the ankles and slight albuminuria. Nothing abnormal was found in the abdomen or nervous system. A skiagram (exhibited) showed enlargement of the heart to the left, with some dilatation also of the right auricle. On screen examination the auricles were seen beating independently of the ventricles with a rhythm of their own. When first seen the pulse was of moderate volume, with occasional dropped beats and a rate of 60 per minute. Within the next month the rate diminished to 48 beats per minute, four months later to 30 per minute, and a fortnight before the meeting was as low as 28 per minute, the patient, nevertheless, being better able to get about and do ordinary light work than he was in the earlier stages of the malady. This fact coincides with the general experience that when heart-block has become complete the patients usually suffer less discomfort than during the period in which the interference with conduction is only partial.

Tracings were shown from apex and radial pulse, in many of which the beats due to auricular contraction could be distinguished, but the value of the electrocardiographic method was evidenced by a series of electrocardiograms taken with different leads (thrown upon the screen), all of which showed clearly auricular beats occurring at regular intervals of time but quite independently of the first and second ventricular waves. Leads I, II, and III showed these especially well, the tracing with axial leads showing the varying relation of one of the auricular beats to the second ventricular (*T* of Einthoven). In the early stages, in the absence of the electrocardiogram, diagnosis would have been with difficulty positive, since in this case, where one most wished to get venous curves in the neck, they were difficult to obtain. Dr. Halls Dally, after referring to the brilliant work of Professor Einthoven, said that he considered this case as an example of the usefulness of electrocardiographic methods in accurate diagnosis of various disturbances of the circulation, and thought that it might be of interest to members of the society if he quoted the concluding paragraph from a personal letter recently received from Dr. Lewellys Barker, the associate professor of medicine in Johns Hopkins University: "It seems to me," said Professor Barker, "that sphygmography and phlebography have now in practical work little more than historical interest provided arrangements are made for electrocardiography."

OPHTHALMOLOGICAL SOCIETY.

A Distinctive Conjunctival Papule.—Operative Treatment of Conical Cornea.—A New Cell Proliferant.—Relief of Tension in Chronic Glaucoma.—Exhibition of Specimens.

A MEETING of this society was held on March 14th, Mr. J. B. LAWFORD, the President, being in the chair.

Mr. H. HERBERT read a paper entitled "A Distinctive Conjunctival Papule." He described a somewhat prominent defined painless papular swelling found on the inter-palpebral ocular conjunctiva, fairly common in India, and apparently rare in Europe. It occurred in adults, chiefly in males, and most often at the inner side of the cornea. It was generally of a pale pink colour, paler than the immediately surrounding injected conjunctiva, and there were a few enlarged blood-vessels running to it. It might stain feebly with fluorescin. It might last two or three weeks only or considerably longer. Its chief histological features were great epithelial proliferation, more or less inflammatory infiltration, and elastic tissue degenerative changes. In the more active cases the epithelial cells were much enlarged, and multinuclear epithelial giant cells were to be found. Where epithelial downgrowths were unable to form, owing to firm supporting fibrous tissue, the nutrition of the epithelial mass was served by the penetration of thin-walled blood-vessels running into it. It was doubtful whether the elastic tissue changes were an essential feature, since they were well developed in the otherwise normal neighbouring conjunctiva. They were the changes which had been described in pingueculæ. Some of the broken-down elastic tissue was carried by the lymph stream into the epithelium, more particularly in the more inflammatory cases. Some of the degenerate material was taken up by the epithelial cells and thus disposed of. Its presence appeared to stimulate the multiplication of the cells. Portions of it, by causing localised proliferation, led to the formation of "cell nests." This observation should be tested as to its possible application to epithelial pearls in other affections, as in epithelioma of the skin. Much of the hyalin degenerate elastic material no longer stained specifically, but showed some newly acquired selective staining affinity, which aided in its recognition. In one case particles of broken-down tissue were also found in the epithelium.

Mr. C. A. WORTH read a paper entitled "Operative Treatment of Conical Cornea," describing a new operation for the condition. In most cases needing operation there was a very high degree of myopic astigmatism, sometimes as much as 15 or 20 D., with little spherical error, and even with the most accurate combination of correcting lenses vision was usually very poor. At the apex of the cone there was usually what looked like an opacity, but examination with oblique illumination and a loupe often showed this appearance to be merely a refraction effect. Most surgeons operated on conical cornea by applying the actual cautery to the apex, whether with or without complete perforation. Some surgeons say that to operate without perforation is to produce a large opacity, and small effect upon the refraction. Those who do not burn a hole completely through the cornea say that the presence, for several days, of a sloughy fistulous opening into the anterior chamber would be a source of grave danger to the eye. The instruments required for Mr. Worth's operation are a platinum thermo-cautery and spirit lamp, and a broad needle and spatula for tapping the anterior chamber. The platinum cautery has a flat surface of an elongated oval shape. The eye is cocainised, and a drop of eserine instilled. A spot is selected on the cornea in the meridian of greatest curvature, nearly midway between the summit and the margin of the cornea. The cautery is heated in the spirit lamp and held over the eye until it almost ceases to glow in daylight. It is then applied to the cornea at the selected spot with its long axis at right angles to the meridian of greatest curvature. It should only be left in contact with the cornea for an instant. Two or three applications are required, the cautery being heated each time. It is endeavoured to make a cavity about 4 mm. long and 2 mm. wide, with steep edges, and extending nearly down to Descemet's membrane, but very great care should be taken to avoid opening the anterior chamber. Descemet's membrane appears to be more resistant to burning than the substance of the cornea, or perhaps the aqueous protects it in the same way as water protects a tin kettle. With care one can continue the cauterisation until the membrane is seen bulging at the bottom of the wound. Then the anterior chamber is tapped near its periphery and the aqueous evacuated. This is done on each of the following three or four days, and after that on alternate days until the ulcer is healed. The main points of the operation are—the dangers of a communication between the wound and the interior of the eye are avoided; the frequent evacuation of aqueous promotes rapid healing of the wound and greatly increases the effect of the operation; by concentrating the effect of the operation chiefly upon one meridian, and so reducing the myopic astigmatism, one gets better visual results than could otherwise be hoped for; no subsequent iridectomy is required. Mr. Worth said the operation was so safe and satisfactory that he would not hesitate to recommend it in a case of non-progressive myopic astigmatism of very high degree.—The paper was discussed by Mr. ERNEST CLARKE, Mr. C. WRAY, Sir ANDERSON CRITCHETT, Major G. F. ALEXANDER, Mr. ARNOLD LAWSON, and Mr. T. HARRISON BUTLER.—Mr. WRAY, in his remarks, expressed surprise at hearing Mr. Worth say that so many cases of the kind were corrected by means of myopic cylinders. The last seven cases he had himself had were corrected by plus cylinders.—Sir ANDERSON CRITCHETT'S observations consisted of a defence of his operation by means of the galvano-cautery.

Mr. A. R BRAILEY read a contribution, entitled "A New Cell Proliferant." He called attention to a new drug, named allantoin, which he termed a cell proliferant. Its action was not that of an antiseptic; indeed, it actually encouraged the growth of organisms; but its great use was that it encouraged the proliferation of the cells of the tissue. He mentioned the case of a small corneal ulcer, which, after cauterising and the application of various remedies, did not get well. Drops of allantoin quickly caused a marked improvement. He mentioned several similar cases, and said it acted by causing extra nourishment to be received by the cornea. The drug was, he said, well worth a trial in long-standing keratitis, and possibly scleritis.

Mr. A. B. ZORAB read a paper on the "Relief of Tension in Chronic Glaucoma: A Preliminary Report on a New Operation." After briefly reviewing the existing operations, he indicated that the guiding principle in each was drainage of the interior of the globe. He then described his own procedure, based on the same guiding principle. He described two methods, of which the second was, in his opinion, the better. Originally he passed a threaded needle subconjunctivally into the anterior chamber, piercing the sclerotic coat at the angle. The needle was then brought out at a corresponding point through the angle and out again subconjunctivally. The ends of the silk were cut short and a little manipulation ensured their being covered by conjunctiva. He found, however, that the conjunctiva was very frequently torn by the fixation forceps, and also there was some risk of pricking the

iris and lens capsule with the point of the needle. Acting on the suggestion of Mr. J. F. Bullar, he modified the operation thus: A large flap of conjunctiva was raised—at the upper part of the globe for choice—leaving a crescentic attachment along the limbus. A small incision was then made under this flap into the anterior chamber. A piece of sterile silk thread, about a third of an inch long, was doubled on itself, and the loop was pushed gently through the sclerotic incision into the chamber. The conjunctival flap was then replaced and stitched in a couple of places, great care being taken to see that the distal ends of the bight of silk did not come near the margin of the conjunctival incision. Mr. Zorab claimed for this procedure that it was quite devoid of manipulative risk, that it established efficient drainage which promised to be permanent, and that it was simple to perform. The only danger, in his opinion, was from sepsis, but he did not regard this as being any greater than the other operations involving opening the eyeball. The greatest emphasis was laid on ensuring a complete covering of the silk by healthy conjunctiva. As the oldest case only dated back to July, 1911, he was careful to state that the operation was only on trial, but he was firmly convinced that it held out good promise. He had so far restricted it to cases of chronic glaucoma, as acute cases did well with iridectomy. He concluded his paper with notes of the cases already operated on.—Mr. M. STEPHEN MAYOU mentioned some cases on which he had tried a similar procedure somewhat before Mr. Zorab.—Mr. ZORAB replied.

The following card specimens were shown and discussed:—

Mr. R. R. CRUISE: (1) A Case of Tuberculosis of the Conjunctiva; and (2) Scotometer for Testing Central Colour Vision.

Mr. WRAY: A case of Subretinal Cyst.

Mr. H. B. GRIMSDALE: Acquired Hypermetropia with Rupture of Choroid.

Mr. G. COATS: Pigmented Cyst lying Free in the Anterior Chamber.—Mr. HERBERT said he saw a similar case to Mr. Coats's in Bombay, but there was no deposit on the lens capsule.

Mr. L. V. CARGILL showed a case of Osteoma of the Frontal Sinus.

Mr. J. F. CUNNINGHAM showed a case of Episcleral Nodule, probably Tuberculous.

Mr. N. BISHOP HARMAN exhibited a case of Guttate Iritis.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Concealed Accidental Hæmorrhage.—Diverticulitis.

A MEETING of this society was held in Sheffield on March 15th, Mr. RICHARD FAVELL, Vice-President, being in the chair.

Dr. D. G. NEWTON showed a specimen of Chorion-Epithelioma.

Mr. A. W. CUFF reported a case of Extreme Vesical Incontinence, associated with prolapsus uteri, successfully treated by laying bare the urethra, putting in some puckering stitches, then doing a very thorough anterior and posterior colporrhaphy and Gilliam's operation.

Dr. G. W. FITZ-GERALD showed: 1. A Mucoid Polypus of the Cervix removed from a patient aged 31. The patient, who had been married for 12 months, complained of dyspareunia, pain in the back, occasional menorrhagia, and a persistent offensive leucorrhœal discharge. The tumour when removed was of the size of a tennis-ball, and was brought before the society on account of its unusual size and the similarity of its structure, naked-eye and microscopical, to that of a malignant adenomatous growth of the cervix and uterus recently shown by Dr. Fitz-Gerald. This tumour showed no indication of malignant change. 2. A Dermoid of the Right Ovary and a Pedunculated Fibroid Tumour, which was attached to the posterior wall of the uterus, removed from a patient aged 70. An interesting feature in the history of the case was that two years before she had suffered from an acute illness, which was attributed to a pelvic tumour. Her condition at that time had been so grave that it was feared she would not survive. She, however, got well. The dermoid showed at its upper end a blood clot of the size of a ping-pong ball, which no doubt was the result of torsion of the pedicle having occurred at the time of the previous illness. She complained of constant pain in the right iliac fossa, and low down in the back.

Mr. MILES H. PHILLIPS (Sheffield) reported a case of severe Concealed Accidental Hæmorrhage, which had been successfully treated by Cæsarean section followed by hysterectomy. The patient was 33 years old. During the previous 13½ years she had had nine full-time labours, and one miscarriage. Until one morning a fortnight short of full time she had been in good health. She was then awakened by severe abdominal pain. She fainted two or three times. There was no external bleeding. Dr. E. T. K. Walker, of Tinsley, recognised the condition, and at once sent her into the Jessop Hospital. On admission she was very pale, with drawn features, and a feeble pulse of 120. The uterus was tense and tender; the child could not be felt. The cervix was thick and firm and just admitted the tips of two fingers. On attempting to rupture the membranes a gush of blood poured down the vagina as if from a tap. A speculum was at once inserted and the vagina tightly packed with gauze. Blood soon began to escape freely through the packing and the pulse became uncountable. Considering that an immediate hysterectomy might give her a chance, the house surgeon, Dr. J. Chisholm, promptly had the theatre got ready and telephoned for the surgeon on duty. On opening the uterus a large quantity of blood and clot escaped. The child was as dead-white as the mother. The placenta was found loose on the posterior wall of the fundus, completely separated from the placental site, which was on the anterior wall. The membranes were intact. The uterus was thin and perfectly flabby. It was at once amputated at a level slightly above the cervix. No hæmorrhage occurred from any of the cut edges. The patient was too bad to move from the hot operating theatre for several hours. Pituitary extract, oxygen, saline infusions, strychnine, and digitalin were used. For 36 hours recovery was very doubtful. Thereafter she made steady progress, which was delayed in the third week by a slight paracervical cellulitis.

Dr. C. OLDFIELD read a paper on Diverticulitis as a Cause of Pelvic Inflammation, with a report of three cases. The disease, he said, was fairly common and well known to surgeons. Although the lesion was usually pelvic, the disease had apparently escaped the notice of gynæcologists. The two chief clinical varieties were: (1) left-sided "appendicitis"; and (2) chronic obstruction. The former might assume various forms just as appendicitis did, and not uncommonly cause pelvic abscess or even general peritonitis. The latter variety resembled obstruction from malignant disease of the pelvic colon, and on exploration, and even after resection of the portion of bowel involved, the disease was usually taken for carcinoma. In nature it was inflammatory and arose in connexion with small multiple diverticula from the colon, particularly the sigmoid. On dissection these diverticula were found to be hernias which took the form of little pockets varying in size from a pea to a hazel nut. The mucosa was herniated through slits in the muscular coat of the bowel and generally projected into the sigmoid mesentery or the epiploic appendages. It would be readily imagined how concretions or foreign bodies came to lodge in these pockets and, further, that inflammatory diseases would result. In operating for pelvic inflammation it was necessary to be mindful of the existence of this disease because, while it simulated left tubo-ovarian disease, its operative treatment was both more difficult and more dangerous. Indeed, the death-rate from operations in chronic cases was very high and was mainly due to the fact that the true nature of the condition had not been determined until after death.

EDINBURGH OBSTETRICAL SOCIETY.

Transplantation of the Ovary.—Lateral Incision of the Perineum.—Measuring Internal Diameters of the Female Pelvis.

A MEETING of this society was held on March 13th, Dr. J. HAIG FERGUSON, the President, being in the chair.

Dr. HUGH S. DAVIDSON read notes on three cases of Transplantation of the Ovary in women in whom palliative measures had failed. As all the women were under 30 homoplastic grafting was attempted, in order to obviate the symptoms following the early menopause. One case was a complete failure. One was a comparative success but was

complicated by the appearance of a fibroid of the uterus; the patient, however, had not shown any menopausal symptoms. The third began to menstruate three months after the operation and had menstruated ever since. None of these patients suffered any return of menstrual pain, nor any pain at that time at the site of the transplantation of the ovary in the rectus abdominis muscle. A mere slice of ovary was embedded into a slit in the muscle. Dr. Davidson considered this method of treating pathological ovarian conditions superior to attempts at conservative surgery, as the transplanted portion had shown no signs of further change in its new situation, whereas pieces of ovary left *in situ* tended to become pathological and thus to require a second operation. While the grafts might not prove permanent, they produced a slowly appearing and consequently milder menopause.—Dr. A. H. F. BARBOUR asked whether the return of hæmorrhage after the removal of the two ovaries was considered as a menstruation. This occurred without transplantation. Had the cases described gone on menstruating for a year? Could the same results be expected from a portion of ovary engrafted into a muscle as from ovaries in the normal position? Did secretion from an engrafted ovary get into the system in the same way? Was there any evidence that ovulation was taking place? However, this transplantation was easily done, and might be practised in many cases and the results watched.—Dr. J. W. BALLANTYNE remarked that the results of transplantation experiments in animals had not so far been successful, but suggested possibilities. The ideal site would be transplantation into the wall of the uterus, and so to continue their secretion and ovulation, with possibly impregnation, as in a case of removal of the tubes.—Dr. F. W. N. HAULTAIN asked whether the menopausal symptoms were equally kept off if menstruation was not established. He always removed the uterus when removing both ovaries. Was this essential in the prevention of the symptoms of artificial menopause? He believed the results attending the removal of the ovaries to be much exaggerated. He had found that of women in certain asylums only 0·5 per cent. had had their ovaries removed, whereas 5 per cent. were without their appendices; so that one was more justified in saying that insanity followed removal of the appendix than of the ovary. He believed the results of the artificial menopause depended wholly on the sexual temperament of the woman.—Mr. E. W. SCOTT CARMICHAEL related the results of transplanting the ovary in 21 rabbits. In 15 there was success and 6 completely failed. Success depended on the site; it was more successful when implanted into muscle than into the broad ligament or on the parietal peritoneum. Transplantation in the human subject should be into muscle. He believed that in women only a slice of the ovary could be transplanted, and that the tendency would ultimately be to complete atrophy; yet even this would temporarily diminish the symptoms. If part of an ovary was left normally attached it would certainly hypertrophy.—The PRESIDENT said that when the ovaries and part of the body of the uterus had been removed he had known menstruation to occur from the lower part of the endometrium, which kept the patient comfortable. Transplantation was an alternative to resection of the ovary, which he had found unsatisfactory, as the portion left tended to become cystic.—Dr. DAVIDSON, in reply, said that the wall of the uterus seemed the best part for the transplantation. Conservative surgery of the ovary was a failure; in every case he had seen a second operation had been required in from 12 to 18 months.

Dr. R. ROBERTSON, in a paper on Lateral Incision of the Perineum and its immediate repair after labour, advocated lateral incision with scissors whenever there seemed probability of rupture. It was required specially in primiparæ, in occipito-posterior cases, and in rigidity of the perineum. Right lateral incision was practised from the vagina to 1 inch outside the anus and for 2 inches up the vaginal wall. There was often free bleeding. After the child was born, and before the placenta came away, the incision was carefully stitched up in layers with catgut, bringing the cut ends of the muscle together, the skin edges being joined with silkworm gut. The incision, if carried out in time, saved detachment of the levator ani from the symphysis, and by preserving the perineum prevented prolapse of the anterior vaginal wall. The stitching was easily carried out.—Dr. HAULTAIN said he had tried lateral incision, but had given it up after a fair trial with varying success.—Dr. B. P. WATSON said he adopted Lapthorn Smith's method. When the patient was under chloroform the thumb was passed into the rectum and the fingers into the vagina, and three silkworm-gut sutures were inserted, passing closely below the mucous membrane of the vagina, the ends of the sutures being held by forceps. If the perineum tore, the sutures were in place for tying; if no tear occurred they could easily be withdrawn.—Dr. J. M. BOWIE considered two small lateral snips better than one large one.—The PRESIDENT, Dr. W. FORDYCE, Dr. J. YOUNG, Dr. H. O. NICHOLSON, Dr. JAMES RITCHIE, and Dr. G. KEPPIE PATERSON joined in the discussion, and Dr. ROBERTSON replied.

Mr. ARCHIBALD MCKENDRICK and Dr. JAMES YOUNG demonstrated an improved method of Measuring the Internal Diameters of the Female Pelvis in the living subject. Mr. McKendrick described the X ray and mathematical aspect of the subject and Dr. Young the anatomical. It was shown, as a result of an exhaustive investigation of dried pelves, normal and abnormal, that the plane of the transverse diameter coincided invariably with a line joining the upper margin of the pubes and the posterior superior iliac spines. The plane of the conjugate was more variable, however, but in 95 per cent. of cases a line joining the upper margin of the pubes and the promontory of the sacrum if prolonged cut the vertebral spines on an average 1·7 inches above the line joining the posterior superior spines. By their method the measurement of the transverse diameter was strictly accurate, but that of the conjugate was in a small percentage of cases liable to an error of about one-tenth of an inch when examined by the X ray pelvimeter. A skiagraph was taken with the patient in the prone position, the X ray tube being 36 inches vertically above the plate. A plumb-line was dropped to the region of the sacro-coccygeal joint and the point marked by a metal ×. The posterior superior spinal line and a point 2 inches above it on the spine were similarly marked, and their respective distances from the photographic plate recorded. The distance of the pubes from the plate was also noted. The X ray exposure was made, and a print or tracing taken and applied to the X ray pelvimeter. The X ray pelvimeter devised by Mr. McKendrick reproduced accurately the conditions under which the skiagraph was taken. The focus point of the X ray tube was represented by a pivot from which cords diverged. These cords represented X rays, and were kept taut by means of steel springs. The axial ray was a fixed cord, and was cut at right angles by a fixed transverse cord 36 inches from the pivot; the other cords were moveable about the fixed pivot. For ease of measurement other moveable transverse cords completed the instrument; these moved up and down on fixed scales at the sides marked in inches. The skiagraph was applied to the pelvimeter in such a position that the mark × (focus point) was at the intersection of the fixed axial and transverse cords, the spines of the vertebræ lying under the transverse cord. The cords representing X rays were now moved till they coincided with the bony points marked in metal, and with the pubes and the promontory on the print. The print was now relative to the instrument exactly as the plate was when the X ray exposure was made, but on a different axis. The original distances of the bony points from the plate were now fixed on the pelvimeter by means of the transverse cords; the intersections of these and the X ray cords represented accurately the original relative position of the bony points. A straight-edge applied to the intersections would represent the plane of the conjugate, and where the X ray cord applied to the promontory cuts the straight-edge would correspond to the original site of the promontory. The exact conditions under which the X ray was taken were thus reproduced by means of the pelvimeter, and a measurement from the pubes point to the promontory points on the cords would give the measurement of the conjugate. In the same way the transverse diameter was measured, but in this case the plane was marked by the straight-edge from the intersection of, first, the posterior superior spinal cord and the transverse cord representing its distance from the plate; and second, the pubes cord and the transverse cord representing its distance from the plate. Where the straight-edge cut a perpendicular dropped to the widest part of the brim formed the point across which the transverse diameter was measured (for example, say 3 inches). The print

was now turned round with × as its centre and brought to lie so that the vertebral spines were in line with the original plumb line. Two X ray cords were then applied to the widest part of the brim of the pelvis and the distance between them (say, 3 inches) would give accurately the measurement of the transverse diameter. The X ray pelvimeter was being manufactured by Messrs. Siemens and Co., London.—Dr. BARBOUR and Dr. E. F. T. PRICE discussed the communication.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Cerebellar Tumour.—X Ray Diagnosis of Aneurysm of the Thoracic Aorta.

A MEETING of this section was held on March 8th, Sir JOHN W. MOORE, the President, being in the chair.

Dr. P. DEMPSEY showed a patient suffering from Cerebellar Tumour and detailed her history. The patient, aged 24, had suffered for eighteen months from headache, chiefly vertical, occasionally occipital, accompanied by attacks of vomiting and giddiness and periods of transient blindness. On admission, smell and taste normal; marked optic neuritis, especially in left eye; vision defective, but could read; weakness of left external rectus; slow, deliberate nystagmus to left; rapid fluttering movements to right; slight paresis of left side of face, and tactile anæsthesia over fifth nerve; hemiparesis; left arm showed jerky, rapid movements of supination and pronation on movement; no tremor when at rest; gait staggering, more so with eyes closed; no marked deviation to either side; knee-jerks exaggerated; plantar reflexes diminished, flexor; leg movements ataxic when the patient was lying down; left arm was pronated and supinated slowly and awkwardly; no sensory defect other than mentioned; no bulging or tenderness of cranium.—Dr. J. CRAIG said there were some features in the case that threw a little doubt on the cerebellar nature of the lesion. It struck him as peculiar that the fifth, sixth, and seventh nerves should be involved without any involvement of the eighth. He had exhibited a case some time ago in which the eighth nerve was involved with the fifth and seventh.—Dr. T. G. MOORHEAD said it was extremely important that physicians should form some opinion as to the value of operation in these cases. His experience of operations performed for intracranial compression was very favourable, so far as the relief of the symptoms was concerned, and he had seen sufficient cases done to convince him that operation was the treatment to adopt in all cases of intracranial tumour. In two cases that came under his notice recently very considerable relief was afforded to distressing symptoms by operation in the parietal region.—Mr. A. J. M. BLAYNEY said he understood the patient had refused operation. The recognised surgical treatment was to perform the decompressive operation, and there was no doubt this gave relief for some time. An argument in favour of the occipital in preference to temporal decompression was that should further operation be afterwards undertaken the necessity for a fresh opening would be obviated.—Dr. F. C. PURSER discussed the exact site of the tumour in this case on the symptomatology of many cases which had been operated on or had come to necropsy. He drew attention to the danger of diagnosing tumour of the cerebellum unless localised symptoms come on, at latest, very soon after general symptoms. He also discussed the value of vertigo as a symptom.—Professor W. H. THOMPSON said that from the physiological point of view the case was a complex one. The chief complications were the ataxia and the Romberg's sign; the other symptoms might be explained by an extra-cerebellar tumour on that side. He was inclined to the view that the tumour was extra-cerebellar.—Mr. A. A. M'CONNELL pointed out that brain surgery differed from general surgery and needed much practice in technique. He called attention to a point regarding diagnosis described by Cushing—viz., that in early cases there is a change in the colour-fields of the eyes known as dyschromatopsia.—Mr. F. K. CAHILL gave his experience of a case of a school-boy in which a diagnosis of brain tumour had been made by the school medical officer. The patient consulted him afterwards, complaining of a pain in his head, and on consultation with Sir Henry Swanzy the conclusion was arrived at that there was no tumour. The boy died four days afterwards, and on inquiry it was found that he had been noticed staggering, but up to that time this symptom had been withheld.—The PRESIDENT summed up the discussion, and Dr. DEMPSEY replied.

Mr. MAURICE R. J. HAYES read a paper on the X Ray Diagnosis of Aneurysm of the Thoracic Aorta. The necessity of remaining for from five to ten minutes in total darkness before making a radioscopic examination of the thorax in order to increase the luminous sensibility of the retina was insisted upon, and in order that the observer may be able to give an opinion of any value it was important that he should be conversant with the X ray appearances of chests that were normal as well as diseased. The diagnosis should be made from the screen examination. The shadows on a negative were likely to be misleading, especially to the inexperienced. With the negative static conditions only could be studied, with the screen dynamic conditions could be observed. The appearances of the normal thorax were fully described, and the different positions in which the thorax should be examined were demonstrated. The differential diagnosis of aneurysms, new growths, consolidation of the lung, enlarged glands, and empyema was discussed, and lantern slides and diagrams illustrating the various points in the paper were shown.—The paper was commented on by the PRESIDENT, Dr. MOORHEAD, Dr. PURSER, and Dr. HARVEY.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 20th, Dr. F. H. Jacob, the President, being in the chair.—A paper was communicated by Mr. Percy E Tresidder and Mr. Stanley Tresidder on the Treatment of Syphilis by "606" or Salvarsan. The former first gave a brief description of the chemical and physical properties of the drug. He briefly outlined the history of syphilis from its introduction into Europe 400 years ago to the discovery of its causative agent in the spirochæta pallida. Mercury had been held to be the sole specific for syphilis until Dr. Ehrlich, of Berlin, discovered salvarsan. Dr. Ehrlich was able to cure inoculated monkeys by means of salvarsan in seven days; he discovered, however, that three months later the cured monkeys could be again inoculated, thus proving that salvarsan did not cause immunity from the disease. A description of the methods employed in administering the drug was then given; the author always used the intravenous method. They generally administered two injections within a fortnight, and then followed with a course of mercury. Certain precautions were necessary; the optic discs should be examined; nor should patients suffering from any of the constitutional diseases—e.g., diabetes, tuberculosis, cardiac diseases, &c.—nor debilitated and old or very young subjects be treated with salvarsan. They kept their patients in bed for 24 hours before the injection and for 48 hours after. Within an hour of the injection the patient's temperature rose to 100° F., and there was general malaise, but after six hours these symptoms subsided and the patient rapidly improved. A Wassermann test of the blood should always be made to confirm the diagnosis, and also should be subsequently made to judge the result of the treatment. Generally, they found six weeks after the injection that the Wassermann reaction was "partially positive," but after a short course of mercury it became negative, and all the symptoms of syphilis disappeared. In cases of skin and mucous membrane lesions the immediate results were marvellous. In cases of congenital syphilis they gave the mother an injection, and this acted upon the child through the milk, in spite of the fact that the milk contained no trace of arsenic. They also found the serum from the blister of an injected patient cured a second patient if injected into him. They had been successful in treating cases of tabes dorsalis, general paralysis of the insane, and a case of severe tertiary glossitis. Finally, a list of diseases that could be cured by the drug was given.—Mr. Stanley Tresidder then read notes of typical cases. They had now employed the drug in nearly 100 cases for a period of over a year. They had never had an alarming complication and their results were striking. He quoted cases where they had successfully employed the drug in primary, secondary, and tertiary syphilis, congenital and hereditary syphilis; in parasyphilitic diseases, such as tabes dorsalis and general paralysis of the insane. On being questioned as regards the latter case, he said the diagnosis had been confirmed by an eminent Edinburgh

specialist, and the man had so far recovered as to be able to travel abroad, although he had only the previous day heard by cable that the patient had unfortunately had a seizure.—A demonstration was then given of the instruments used, and two cases were shown illustrating the curative results of the drug.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Devon and Exeter Hospital on March 8th, Dr. R. V. Solly, the President, being in the chair.—Dr. W. Gordon read notes on a case of Cancer of the Œsophagus with Perforation, in which the Boas-Oppler bacillus was recovered from the lung tissue during life.—The President remarked that he had found the bacillus in a considerable number of cases of gastric cancer, and considered its presence or absence of distinct value in arriving at a diagnosis.—Dr. J. Raglan Thomas asked Dr. Gordon if radium had been tried in this case, and related a case under his own care where radium had been applied to an œsophageal growth, but unfortunately discontinued by the patient. A post-mortem examination by a skilled pathologist testified to distinct healing having taken place at the point of radium application.—Mr. R. A. Worthington reported in brief and showed specimens from (1) Endothelioma of the Palate; (2) Cancer of the Large Intestine in which a portion of the growth was passed per anum; and (3) Polypoid Tumour springing from the supratonsillar fossa.—Mr. H. Newman showed the following cases for Dr. Henry Davy: (1) A girl with Erb's Juvenile Form of Muscular Dystrophy; (2) a young woman with Exophthalmic Goitre in whom symptoms of myxœdema coexisted; and (3) a man with Cerebral Gumma under treatment with injections of salvarsan.—Dr. Gordon showed cases of: (1) Aortic Regurgitation in a young girl in whom anginal attacks had occurred; the attacks were relieved by the nitrites and by salicylate of sodium; and (2) Mitral Stenosis. Dr. Gordon also read notes on a case illustrating the Value of the Cardiac Sign in Cancer. The patient was found after delivery to have a tumour in the lower abdomen, and the consensus of opinion favoured a diagnosis of malignancy. The presence of a normal area of cardiac dulness caused Dr. Gordon to reconsider the diagnosis, and eventually the presence of tubercle bacilli in the urine was established and the true nature of the tumour arrived at. Dr. Gordon stated that in about 100 cases 90 per cent. were found to have reduced cardiac dulness.—Mr. Worthington, who had examined the woman with the cystoscope, had noted an ulcer on the posterior vesical wall, and he thought possible that a tuberculous growth of the mesentery had formed adhesions to the bladder.—Dr. J. Delpratt Harris showed a Sacral Tumour which he had removed from a woman aged 26. The tumour proved to be a dermoid; it had caused no inconvenience until quite recently. The excision was performed with considerable difficulty owing to deep extension into the pelvis and intimate attachments to the posterior rectal wall. Dr. Harris also showed X ray negatives of: (1) Renal Calculi; (2) Ureteral Calculi; (3) Phleboliths, and pointed out how easily (2) and (3) could be confused by the unwary.—The President showed a Tumour of the Testis, the growth having occurred in a retained organ.—Mr. Russell Coombe, in commenting on the case, recollected one where myxosarcoma of the testicle at first suggested hydrocele. He remarked on the high grade of malignancy and the rapid recurrence in such cases.

LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held on March 19th, Dr. Morgan Dockrell presiding.—The following cases were shown and discussed: (1) A Syphilide Resembling Lupus Vulgaris, by Dr. J. L. Bunch; (2) Pityriasis Rubra, by Dr. W. Griffith; (3) Pityriasis Rosea and a series of cases of Keloid treated by local hyperæmia and X rays, Dr. W. Knowsley Sibley; and (4) Acne Vulgaris Treated by Vaccines, Dr. T. Galbraith.—The President read a paper on Lichen and Lichenification and showed a series of cases and microscopic slides to illustrate these conditions.

WORTHING HOSPITAL.—It has been decided to instal an X ray apparatus and electric bath at Worthing Hospital as a memorial to Mr. Augustus H. Collet, who for 37 years was one of the medical officers of the institution. Mr. Collet died in March, 1909

Reviews and Notices of Books.

The Growth of Bone: Observations on Osteogenesis. An Experimental Inquiry into the Development and Reproduction of Diaphyseal Bone. By Sir WILLIAM MACEWEN, M.D. Glasg., F.R.S. With 61 figures. Glasgow: James Maclehose and Sons. 1912. Pp. 210. Price 10*s.* net.

THIS inquiry was undertaken to test by direct experiment problems connected with the growth of bone, and was carried out for the most part "on the canine species" in the developmental period. According to the author, this was necessary, "as a firm belief exists that all periosteum produces bone—such is the physiological teaching—many believing that diaphyseal bone could not be produced without periosteum, and, once produced, would die were the periosteum removed." He says that previous experience in human physiology had indicated that the periosteum was not osteogenic, but not so convincingly to the mind of others as direct experiments have demonstrated. He speaks of "the osteogenic potency of the growing shaft," not the periosteum, as the true cause of the filling up of blanks in the shafts of growing bone. In the end, of course, it is the osteoblasts that build up bone.

Beginning with the genesis of the osteoblast, we are told that "the nuclei of the cartilage cell divide and are set free as osteoblasts." This is certainly not the usual teaching as regards the origin of osteoblasts. It is also stated that "the growth occurring at the normal epiphysis is governed by inherent heredity." We may remark that very few of the historic names associated with investigations on bone production and regeneration—except those of Duhamel and John Hunter—are mentioned. We were unable to find any reference to the well-known work of L. Ollier, of Lyons, "Traité Expérimentale et Clinique de la Régénération des Os" (1867), some of whose results are in direct contradiction to those of the author.

Besides its other functions the periosteum is regarded as a limiting membrane to the osteoblasts. The author then proceeds to discuss the question, "Has the periosteum inherent osteogenic power?" A portion of the shaft of the radius was removed subperiosteally, the periosteum being left *in situ*. After ten weeks there was a gap between the ends of the bones where the periosteum was left intact, but new bone had been produced by the shaft: even when the whole radial shaft is removed, the periosteum being left intact, no new shaft has formed. "There was an entire absence of ossific reproduction from the periosteum." A flap of periosteum raised from the shaft of the radius and made to surround a muscle did not result in bone formation. Transplanted periosteum, we are told, does not produce bone. Let anyone read Ollier's account of his experiments and study the illustrations showing the production of bone by transplanted periosteum, and even the growth of bone on a cockscomb, and he will see that there is a wide gulf fixed between the results of Sir William Macewen and those of the earlier experimenters in the city on the Rhône and the Saône. Ollier distinctly states that the periosteum of all bones is not equally potent when transplanted. That of long bones is more "favourable" than that of flat bones, and amongst these the "juxta-epiphyseal" periosteum is the most prolific.

The author raised a flap of periosteum from bone except at the proximal extremity and caused it to encircle a "muscular fasciculus." There was no bone formation. A similar experiment was made by Ollier on the tibia of a dog with resulting bone formation, which is depicted in an illustration. Who is to decide when such diametrically opposite

results are found between the experiments of two such distinguished surgeons—albeit the experiments of Ollier were often accompanied by suppuration, while those of Sir William Macewen were, of course, aseptic throughout? Ollier showed that if he transplanted under the skin the scrapings from the inner layer of the periosteum—i.e., the osteogenic or osteoblastic layer—they produced little grains of bone in a rabbit 4½ months old. The next question submitted to direct experiment was "the osteogenic power of bone bereft of its periosteum." On removal of this "limiting membrane" the osteoblasts escape and mingle with the other tissues. On removal of the periosteum from the entire shaft of the radius, after 12 weeks new bone has formed on the shaft. Those interested in this question should read Ollier's account of his experiments. On repeating Duhamel's silver ring experiment it was found that on a silver ring being applied to bone denuded of its periosteum the osteoblasts were poured out of the shaft, increased the thickness of bone, and covered the silver ring with osseous tissue.

Next bone grafting without periosteum is considered, and it is shown that rings of bone without periosteum, when broken up into small fragments, reproduced bone if transplanted to a gap cut in bone devoid of periosteum. Shavings of nude bone were transplanted between the muscles where they united and formed again the continuity of the shaft Osseous shavings inserted into the intermuscular septa of the neck in seven weeks formed one dense plaque of bone. A portion of the entire circumference of a bone and its periosteum was removed and in its place was inserted a glass tube. It was found that bone grew into the glass tube from the osseous tissue in the centre of the shaft to the exclusion of all other sources. Occasionally in injuries osteoblasts may be carried a short distance by the blood stream and form bone—e.g., over the sac of a false aneurysm; and the same is true of pieces of bone carried amongst the muscles, a case being given in a man with fracture of the femur, where all details are fully cited and figured. Flat bones, such as those of the cranial vault, can continue to grow and proliferate after losing their periosteum when they are re-implanted, an interesting case in the author's practice being quoted.

Another series of experiments on the same lines as those already mentioned was undertaken to test the osteogenic power of the epiphyseal cartilaginous plates in the regeneration of bone—e.g., the diaphysis was removed subperiosteally, one epiphysis damaged and the other left intact; metal caps were placed on the divided extremities of the shaft of the diaphyseal side of the epiphyseal cartilages, while the remainder of the shaft was removed. The author found that the new growth came from the epiphyses and not from "reproduced periosteum."

Physiologists and surgeons will alike find Sir William Macewen's book both valuable and suggestive. The results are extensively illustrated by numerous excellent photographs. Some of the author's own cases are particularly interesting, including one of restoration of the transverse ramus of one-half of the jaw by transplantation of bone in a girl.

Text-book of Ophthalmology. By Dr. ERNST FUCHS, Professor of Ophthalmology in the University of Vienna. Authorised translation by ALEXANDER DUANE, M.D., Surgeon, Ophthalmic and Aural Institute, New York. London and Philadelphia: J. B. Lippincott Company. 1911. Pp. 989. Price 25*s.*

THE fourth American edition of Professor Fuchs's "Text-book of Ophthalmology," following the third edition at an interval of only three years, shows the demand for this standard work. To a cursory examination it appears to be the same work, but whereas the last English edition was a translation of the eleventh German edition the present contains many additions, both in the text and in the illustrations, derived from the twelfth German edition. Most noteworthy amongst these is a completely new section of 67 pages on the general physiology, pathology, and therapeutics of the eye, which is placed in the forefront of the book. It is an admirable introduction to the more detailed considerations which follow. It presents the student with a thoroughly scientific survey of general eye conditions and their treatment, thus enabling him to obtain a view which places everything in its proper perspective. In the general physiology the coats of the eye are especially treated of in relation to their physiological functions, and the circulation of the lymph and intraocular pressure are given a position of prominence which emphasises their importance to the student of eye diseases. General pathology deals successively with causes of injury—physical, mechanical, chemical, and parasitic—degenerative processes, congenital defects, and hereditary influence, and the general symptoms associated with eye diseases. Under General Therapeutics hygienic regulations, dressings, physical methods (heat and cold, radiotherapy, Bier's hyperæmia, and so on), medical treatment (mydriatics, miotics, &c.), and causal treatment, including serum therapy, are considered.

The main part of the text of the book remains much the same as in previous editions. Here and there sentences or paragraphs are modified or brought up to date by reference to new suggestions and methods, such as, for example, Lagrange's operation for glaucoma. Throughout the translator has added his own comments, and in some cases whole chapters, especially in the sections on functional examination, motor anomalies, refraction, and operations. These additions are enclosed between brackets and signed with an initial. They are so frequent and sometimes so extensive that it is often difficult to know whether one is reading the author's or the translator's opinions. As we mentioned in reviewing the last edition, in our opinion the translator has reached, even if he has not already overstepped, the bounds of legitimate annotation. The undergrowth is getting so dense that it is difficult to see the trees. A translation should be as nearly as may be a replica of the original picture; it is impossible to retain the same balance of values in an oil painting and a mosaic. Nevertheless, Professor Fuchs's text-book has been, and still remains, *facile princeps* among the text-books on ophthalmology.

Studies in Cardiac Pathology. By GEORGE WILLIAM NORRIS, A.B., M.D., Associate in Medicine at the University of Pennsylvania, Visiting Physician to the Episcopal Hospital of Philadelphia, Assistant Visiting Physician to the University and to the Philadelphia General Hospitals, &c. With 85 original illustrations. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 233. Price 21*s.* net.

A KNOWLEDGE of the morbid anatomy of the heart is an essential for the adequate consideration of the problems of cardiac pathology and for a proper appreciation of the clinical signs of cardiac disease. Many of the questions concerned are so definitely mechanical that a discussion of the size of the cavities and of their walls, and of the character, texture, and competence of the valves, becomes of the utmost importance. These matters are dealt with fully, and in an instructive and interesting manner in Dr. Norris's book. It is founded upon a study of the specimens in the museums of five of the most important hospitals of Philadelphia. Permission to photograph the specimens having been accorded to Dr. Norris, he has given 85 full-page plates, which obviously give the appearances with remarkable

fidelity. The plates are photographic reproductions, and the lighting and arrangement of the specimens have been admirably managed, so that each plate shows clearly the pathological condition which it is intended to illustrate. To each plate is given some explanatory letterpress, usually comprising brief clinical notes, a description of the heart and of the lesions it presents, and in some cases brief notes on the microscopical appearances.

The plates and accounts would alone make the book valuable and interesting, but Dr. Norris has further increased its usefulness by giving in addition a thoughtful and systematic account of the morbid anatomy of the heart, using his plates as illustrations. He deals first with acute endocarditis, differentiating the various forms of this condition and describing their effects. He then discusses chronic endocarditis, and considers separately the lesions of each of the valves, carefully describing their effects on the cavities and on the cardiac physiology. The other subjects considered are pericarditis, hypertrophy and dilatation, cardiac aneurysm, cardiac syphilis, and congenital lesions. The accounts given are not simply transcriptions of ordinary text-book descriptions, but are the outcome of an extensive study of the literature, to which numerous references are given. Statistics derived from special monographs and from the author's own experience are also given in regard to many conditions. Where opinions differ in regard to the explanation of some manifestation Dr. Norris is careful to recount them impartially. He refers to some interesting personal observations on the occurrence of endocarditis and pericarditis in association with tuberculous disease, to which special notice may be directed.

The book is printed in large type upon very good paper, and, as we have said, the illustrations are admirable. It should be a useful companion to anyone working in a museum or in the post-mortem room.

Maladies de l'Œsophage. Par MICHEL GANGOLPHE, Professeur Agrégé à la Faculté de Médecine de Lyon, Chirurgien-Major Honoraire de l'Hôtel-Dieu. Avec 39 figures intercalées dans le texte. Paris: J. B. Baillière et Fils. 1912. Pp. 115. Price, paper, 3 francs; boards, 4 50 francs.

THIS volume forms part of "Nouveau Traité de Chirurgie Clinique et Opératoire" published in fasciculus form under the editorship of A. le Dentu and Pierre Delbet. Within recent years the diagnosis and treatment of diseases of the œsophagus have been considerably modified, one might say revolutionised, by the development of the means of direct ocular inspection called œsophagoscopy. This, apart from the serious and distressing nature of the maladies, justifies the publication of monographs dealing exclusively with the region.

Professor Gangolphe, within a brief space of 115 octavo pages, presents a summary of the diseases and their treatment. He deals successively with the surgical anatomy, the examination of the œsophagus and its malformations. Next he considers spasmodic strictures of the œsophagus, the infectious and parasitic diseases, the results of inflammation and injuries of the structure. He then discusses the treatment of foreign bodies and of cicatricial contractions, and concludes with a chapter on new growths of the œsophagus. Prior to the development and practical application of œsophagoscopy these diseases baffled the practitioner and were dealt with blindly, more particularly in cases of foreign bodies and strictures which, perhaps, baffled the best observers and clinicians. It is a mattter of common knowledge that foreign bodies usually lodge in the upper part of the œsophagus near to its mouth, which contracts upon and grips the obstructing body. When the body is arrested lower down it is not uncommonly due to blind propulsion by a probang. Œsophagoscopy is steadily diminishing the unfortunate results of groping in the dark. Nevertheless, the modern scientific method of treatment continues to be received in some quarters in a stepmotherly manner. For these reasons it is to be regretted that in the present monograph more space was not devoted to œsophagoscopy and to the description and illustration of the more recent instruments devised for direct ocular inspection, the most important improvement in this connexion being the extensible double tube, by means of which the entire œsophagus can be inspected without any preliminary blind probing.

This volume is an introduction to diseases of the œsophagus, and will be found to contain a considerable amount of information compressed within a small compass.

Records of the School of Medicine, Cairo. Vol. IV. The Anatomy and Life History of Agchylostoma Duodenale (Dubini): A Monograph (Part II.). By ARTHUR LOOSS, Ph.D., Professor of Biology and Parasitology. Published for the Ministry of Education, Egypt, by the National Printing Department, Cairo. 1911. Pp. 613, with 19 Plates.

IT appears peculiarly appropriate that a work on the ankylostoma duodenale should be written in Egypt. One investigator has said that there are grounds for believing that about a fourth of the population of Egypt suffers from this intestinal parasite in a greater or less degree. It has also been contended that ankylostomiasis has existed in the country as far back as there exist any medical records in Egypt. Two German observers, Joachim and Schenthauer, have found in the Ebers Papyrus, which is said to date back to 1530 years before the commencement of the Christian Era and 200 years before the Jewish Exodus took place, some evidence which they regard as pointing to the prevalence at that far distant time of a disease with symptoms suggestive of Egyptian chlorosis. But whether this be so or not, it is undoubted that Egyptian medicine has always been much concerned with the treatment of parasitic worms. It is therefore fitting that a great helminthologist like Professor Looss, actually resident in Egypt, should gather up all the facts known about this particular worm, and should add his own practical and laboratory experiences, making together the most complete work on this subject which has yet been published.

This monograph may be described in a single word, which is in common use among Professor Looss's countrymen, as "colossal." It sets out, with characteristic Teutonic attention to detail, all the points associated with the life-history of the ankylostoma duodenale, its development and the distinctive features of the eggs and larvæ, special mention being made of its development outside the host. The modes of infection are fully discussed and the author's own personal experiences, whereby he contracted ankylostomiasis, are related; the migration of larvæ and the symptoms produced thereby in man are also considered. The comparative frequency of the two modes of infection, by the mouth and by the skin, are duly dealt with. Professor Looss appears to have had in the past some reason for complaint that his views were misrepresented by some rival helminthologists; and in making reply he does not spare his opponents. But he good-naturedly explains that he is cruel to be kind, and that as a medical man must sometimes inflict pain before he can heal, so his replies to his opponents are to be regarded in the same light. Progress in our knowledge of the life history of this worm, he thinks, has been hindered by some of the investigators, "though good doctors," being "poor biologists." The heavy task of revising the translation of this work into English has been very successfully carried out by Dr. H. P. Keatinge, director of the Medical School at

Cairo. Professor Looss gives his reasons for using the word "agchylostoma" instead of the term "ankylostoma," more generally used. It is impossible, however, to get over the fact that the Greek γ before a guttural is, and always has been, sounded as n, and was always so Latinised, and by consequence so Englished—e.g., ἀγγελος, *angelus*, angel, to choose one out of innumerable words in common use.

This monograph must prove of the greatest service to all who seek for knowledge respecting the ankylostoma duodenale and Egyptian chlorosis.

A Handbook of Medical Diagnosis for the Use of Practitioners and Students. By J. C. WILSON, A.M., M.D., Professor of the Practice of Medicine and Clinical Medicine in the Jefferson Medical College, and Physician to its Hospital. Third edition, thoroughly revised. London and Philadelphia: J. B. Lippincott Company. Pp. 1438. Price 25*s*.

THE subject matter of this handbook is divided into four parts with a view of simplifying the arrangement of the topics in a department of medicine which has attained large scope and importance. The first part, "Medical Diagnosis in General," considers the boundaries and relations of the external parts and internal organs of the body, and is rendered more explicit by excellent photographs and diagrams. Students will find the remarks on case-taking well worthy of study.

The second part of the work is concerned with certain methods employed in diagnosis and their results. In considering physical examination, inspection, palpation, mensuration, percussion, and auscultation are well described, but the details given are rather too minute and numerous and are likely to give rise to confusion in the minds of students just entering on their practical studies in the hospital. The examination of the blood, the urine, and the sputum is fully discussed, and the conclusions to be drawn from the results are well set forth. The section on the examination of the nervous system deserves special praise. The preliminary considerations on the "neuron" will be found most instructive both by students and practitioners, whilst the significance of the various symptoms and the behaviour of the reflexes is plainly and succinctly laid down.

In the third part, "symptoms and signs"—i.e., the clinical phenomena of disease, both subjective and objective—the student will find many instructive hints and suggestions, which by helping him to cultivate his powers of observation will prove of service to him throughout his professional career. In the fourth part the diagnosis of various diseases is discussed according to the usual classification adopted in medical text-books, and sections are devoted to the diagnosis of the chronic intoxications, food poisoning, auto-intoxication, and constitutional diseases, such as gout and diabetes. This portion of the work will prove valuable for reference by the practitioner, for the information sought can be readily obtained, owing to the free use of large type to indicate the various subjects, each disease being described under the successive subheads of etiology, morbid anatomy (very briefly given), symptoms, physical signs, diagnosis, and prognosis. A full and complete consideration is thus given to each malady.

The present edition has been brought fully up to date, and the most important advances in the knowledge of diseases and their diagnosis have been incorporated. The illustrations are excellent and considerably aid in the elucidation of the letterpress.

Handbook on Military Sanitation for Regimental Officers. By K. B. BARNETT, M.B, B.Ch. R.U.I., F.R.C.S.Irel., Major, Royal Army Medical Corps. With an Introduction by Lieutenant-General Sir HORACE L. SMITH-DORRIEN, K.C.B., D.S.O., A.D.C. 1912. London: Forster, Groom, and Co., Limited. Pp. 176. Price 2*s*. 6*d*.

THIS small handbook has been prepared, as its title indicates, for regimental officers of the army at home and abroad, not only for examination purposes, but also as a guide in their daily duties in barracks, camp, and on the line of march.

The author very rightly draws attention to the fact that the popular idea of sanitation is "something to do with drains and smells," but it has a much wider significance, and in its application to military life includes all the methods to be adopted for preserving the health of the soldier in peace and war, at home and abroad. Nelson, in 1804, wrote: "The great thing in all military service is health; and you will agree with me that it is easier for an officer to keep men healthy than for a physician to cure them." The present Army Medical Service dates from the introduction of sanitation and many other much-needed reforms in the army at the end of the Crimean war. This was chiefly brought about by the historical letters of the late Sir William Russell to the *Times* describing the awful condition of the troops in the trenches and hospitals before Sebastopol. Sidney Herbert, Secretary of State for War, wrote in the year 1859: "If the education of military officers comprehended a knowledge of the principles of sanitary science, commanding officers might safely be left to their own judgment in adopting sanitary precautions for protecting the health of the men." In 1861 regular lectures on sanitary matters were delivered at the Military School of St. Cyr to the officers of the French army. In the United Kingdom it was not until 1906, four years after the South African war, that a "School of Army Sanitation" was opened at Aldershot at the instigation of Sir Alfred Keogh, K.C.B., Director-General of the Army Medical Service, for the instruction of officers and men of the British army; and by Army Order 3, dated January, 1908, all officers before promotion to the rank of captain and all cadets before appointment to commissions in the regular forces are required to pass an examination in sanitation, as was suggested by Herbert in 1859.

This small book will prove of value to regimental officers, as it is simple, practical, and easily understood, for technical terms have been avoided where possible, and, when included, are explained.

MISCELLANEOUS VOLUMES.

In *Charles Dickens as Editor*, by R. C. LEHMANN (London: Smith, Elder, and Co. 1912. Pp. 404. Price 12*s*. 6*d*), the reader will learn something of the constant vigilance, the unremitting toil, the constant weight of responsibility to public, author, and publisher alike, that are required of a conscientious editor. The book consists of a series of letters addressed to Dickens's sub-editor, Mr. W. H. Wills, covering the period of his editorship of the *Daily News*, *Household Words*, *Once a Week*, and *All the Year Round*—viz., from 1848 to 1870. There is little or nothing of special medical interest in the book, the only references by name that we can find to medical men of note being to an expected call from Mr. (later Sir) Erasmus Wilson, and to Sir Charles Shaw, "for many years the first surgeon at the Middlesex Hospital." The violent opposition in 1856 of Miss Harriet Martineau to the factory laws is interesting. She is said to have stated in a very vituperative pamphlet championing the

manufacturers that "The issue to which the question is now brought is that of the supersession of either the textile manufactures or the existing factory law. The two cannot longer coexist." The factory laws have, however, not only continued to exist, but their application has since been widely extended, while the textile industries are not yet defunct. In one of his letters Dickens says: "I cannot bear the notion of the 'Academy for Cooks' going next to 'Illiberal Doctors'" (published in *All the Year Round*, February, 1863), but whether it was the purveyors of meat or the purveyors of medicine for whose susceptibilities he was so solicitous we are not told. He also tells us that being shaken by the constant express travelling occasioned by his reading tours: "Said the doctors, 'Take warning. Stop instantly.' I made the plunge and became, please God, well." Truly a sensible patient! One little touch of real human charity may be earnestly commended to the attention—and imitation—of the numerous tribe of vicarious philanthropists, both in and out of Parliament, who so earnestly yearn to alleviate the sufferings of the unfortunate at the doctor's expense. He writes in January, 1856, to Mr. Wills as follows: "Will you send John [his own servant] to Mr. Morgan, our family apothecary (John knows his house near Russell-square), with a note asking him to call upon you at the office at a certain time? When he comes, will you tell him that you have it in charge from me to beg him to charge his attendance, medicines, &c., for Mrs. Hogarth in her illness to my account, and just to say nothing at all about the matter to her, or her family, or any one else."—We recognise the grand novelist and moralist that Dickens was when we try to read the modern novel written to caricature and chastise our social vices. No one could be more wildly sensational than Dickens, and no one more hopelessly sentimental; yet the English-speaking world hung on his lips, and time after time social reform followed his teachings. Those who delight in slang, socialism, or sensation, one or all of them, may sup full with horrors by a perusal of *An Enemy to Society*, by GEORGE BRONSON-HOWARD (London: T. Werner Laurie. 1912. Pp. 350. Price 6*s*.). But we doubt if any reformation will follow upon his onslaughts on the wicked. A socialist of criminal instincts works upon a poor tradesman in New York through the commercial wrongs inflicted upon him by an unscrupulous trust magnate to kidnap the latter's infant son. This son is brought up as an "enemy to society," and instructed in the arts of card-sharping and burglary under the guise of philanthropic socialism, and taught that to rob the wealthy oppressors of the poor is the whole duty of modern chivalry. The lad, apparently being devoid of any conscience to admonish him that even those desirous of doing good must not attain it by means in themselves evil, throws himself with the zest of unsophisticated innocence into a career of crime, attaining at the same time an enviable reputation as a philanthropist with the fruits of his crimes. Needless to say, his instructors, whose love for the oppressed poor is by no means equal to their hatred of the oppressing rich, show no such weakly sentimentality about their own shares of the plunder which he is their catspaw for obtaining. When the hero falls in love—as it happens, with the ward of his unknown father—he awakens to the falsity of the fiction wherewith his actions have hitherto been guided, and it recoils on his mentors like a boomerang. Presumably the book is intended to convey a moral. Whether it is that socialism is the ideal morality or that socialists are *au fond* as selfish as other people, that nature is stronger than nurture or nurture than nature, it is hard to say. All that we have been able to deduce from the story is that card-sharping and burglary are not only not reprehensible, they are indeed actually righteous and salutary, provided they are practised against trust magnates and other unscrupulous wealthy people. The book contains, however, a remarkable *exposé* of the methods of the New York police, and of the political and administrative corruption in that city.

In THE LANCET of April 22nd, 1911, p. 1090, we discussed editorially the plan for the organisation of a National Medical Service, elaborated by Professor Benjamin Moore in his book "The Dawn of the Health Age," and while admitting that the ventilation of such views, leading as they do to thinking about the fundamental issues, serves good purpose, we expressed our conviction that such a plan as was there proposed was not at present at any rate practical, if for no stronger reason at least because it would be unpalatable to the medical profession and the public alike. This same comment applies equally to *A National Medical Service*, by F. LAWSON DODD, M.R.C.S. Eng., L.R.C.P. Lond. (Fabian Tract, No. 160. London: The Fabian Society. 1911. Pp. 20. Price 2*d*.), which is a very well-written presentation of the same general principles, lacking their detailed mode of application, as those submitted in Professor Moore's book. Mr. Dodd, however, urges that the transition could be effected without undue disturbance by increasing the efficiency of the public departments of medicine until the individual demand for curative advice and medicine became largely reduced as a consequence of the collective demand for information as to how to suppress or improve the callings and home conditions that kill and maim. Thus, he thinks, the centre of gravity of medicine will leave the curative and tend more towards the preventive side of medicine, rendering practicable in the future the establishment of a National Medical Service.—Mr. J. B. Pike, M.R.C.S. Eng., honorary surgeon to the Loughborough General Hospital, discusses the National Insurance Act in a pamphlet bearing that title (Loughborough and London: John Corah and Son. Pp. 15. Price 3*d*.) in both a briefly explanatory and a critical manner. He describes the intention and scope of the Act; the obligations upon employers, employed, and the revenue; the benefits; the relation of the Act to the medical profession and the Friendly Societies, to the Poor-law service, and to the voluntary hospitals. In regard particularly to the relation of the Act to the medical profession Mr. Pike insists that the proposed arrangements under the Act would perpetuate some of the worst features of the Friendly Society organisations; that Mr. Lloyd George is mistaken in assuming that the present contract arrangements are largely countenanced, for "some of them are disapproved by the General Medical Council and unrecognised in practice"; that as a matter of fact the suspension of medical benefits under the Act, so far from being disastrous for the doctors, would be the best thing in the world for them; and that "by the organisation of public medical services throughout the country the profession can work side by side with the Act and in coöperation with its legitimate aims." This last course he regards as the true solution of the present *impasse*, the feeling in favour of which is rapidly gaining ground. In an appendix he gives the rules and by-laws of the Loughborough Provident Medical Association established just 20 years ago, and consisting of "all medical men willing to coöperate in the work of the institution at present practising privately in Loughborough, with such additions as may from time to time be decided upon by the committee," wherein such essential principles as freedom from outside control, choice of doctor, and an income limit of £2 a week are in successful operation.

In *A Digest of the Laws and Regulations of the Various States Relating to the Reporting of Cases of Sickness* (Washington: U.S A. Government Printing Office. 1911. Pp. 191), Assistant Surgeon-General John W. Trask, of the United States Public Health and Marine Hospital Service, abstracts these

laws under the heading of the States arranged in alphabetical order, analyses them in tabular form, and appends extracts in the *ipsissima verba* from recent laws enacted by the various States on the subject. The peculiar character of the United States constitution, whereby each individual State is absolutely autonomous in all matters of police, which includes care for the public health, renders a lack of coördination a source of peril to neighbouring and even remote States, in consequence of the facility of commercial and personal intercourse due to good roads and rapid transit. Some of the author's remarks, however, apply to all countries. For instance, a failure on the part of practitioners to perform the essential duty of notification of prescribed diseases is not confined to the United States. Similar defaulters are to be found occasionally in other countries. Surgeon-General Trask suggests that "where the State issues licences permitting the practice of medicine, one of the most reasonable penalties which it might be expected to impose on physicians who did not comply with the laws [relating to notification] would be the suspension or revocation of the licence." In regard to the vexed question as to what diseases should be made notifiable, there is wisdom in the remark that "there would seem to be decided advantages in making notifiable all preventable diseases, and that these might be considered to include infectious diseases, certain parasitic diseases, occupation diseases, and certain diseases due to damaged foods." The pamphlet is a useful publication of reference for those interested in the study or practice of public health.

JOURNALS AND MAGAZINES.

Æsculape. Vol. II., No. 2. February, 1912. Paris: A. Rouzaud.—In this number Dr. Laignel-Lavastine writes a final article on the Utility of Classical Studies for the Medical Career. He considers the influence of such studies on the formation of the medical character, and traces the decay of culture in French medical students since 1902 to the abolition of compulsory classical studies, for the restoration of which to the curriculum he submits a scheme. Dr. H. M. Fay continues his researches on the "Cagots" and the Church. According to him the "cagots" (as generally understood, cretins) were really the lepers of the Middle Ages, and he reproduces several of the grotesque heads and figures from fonts and capitals to confirm his contention. Count Robert de Montesquiou discusses the peculiar art of Rodolphe Bresdin, and Dr. Lucien Libert, in "Paysages et Cités d'Orient," gives a fascinating account of the Greek lands. Dr. Léon Demonchy traces historically the ideas on the therapeutic value of music, and essays to show that music-therapy has its foundations not merely in empirical observation but in true physiological conditions. Dr. H. Gougerot and Dr. M. Dogny give a very interesting antiquarian study of hospital internes, the "élèves chirurgiens" of early days, founded on their discovery of certain hospital documents of the old Hôpital St. Louis and its parent institution, the Hostel Dieu. The decree, dated June 9th, 1679, establishing the order of "élèves chirurgiens" is given. M. André Baud makes a contribution to radium-therapy in tuberculosis.

The Child.—In the March issue Mrs. Mary D. Scharlieb, M.D., contributes an excellent article on the morals of the young. She brings under consideration the factors in the making of morals—heredity and environment; the foundations of character—discipline, obedience, self-denial, and self-control; hindrances to morality—overcrowding, poverty, improper feeding or clothing, vices (such as juvenile smoking, drinking, and gambling), and premature emancipation from discipline; helps to morality, in which she includes (besides the opposites to the hindrances) team games and military training. With regard to the last-named she says: "Military training is useful in much the same way as team games, and probably one of the greatest boons to the young people of the land would be compulsory military training for a short time during adolescence, but until this end is attained we must seek to develop a very considerable extension of the present movement for the formation of Territorial Corps, Lads' Brigades, Boy Scouts, and Girl Guides. The moral element comes into all these, and into none more prominently and happily than into the Boy Scout movement with its simple vow of obedience, of self-denial, and of loving help to the aged and defenceless." Dr. Alice Burn discusses the clothing of children in relation to physique and development. Dr. David McKail considers eyestrain in school children, and Edith H. Hewett the teaching of deaf children. "A Child Garden in a Slum" is the title of a delightful pen-picture of a free kindergarten in Salford, for children aged from three to five years, by Mrs. W. F. Lofthouse, who urges on groups of leisured women citizens this opening for a definite social service, which costs about £130 a year. Dr. L. D. Cruickshank describes child welfare work in Dunfermline. Professor C. H. Herford, Litt.D., gives a biographical note of William Henry Herford, a pioneer of child study, and Madeline Bateman describes Westfield College, Hampstead, for women students of the University of London. The Birmingham and District Cripples' Union is the subject of a paper by Mary Champness.

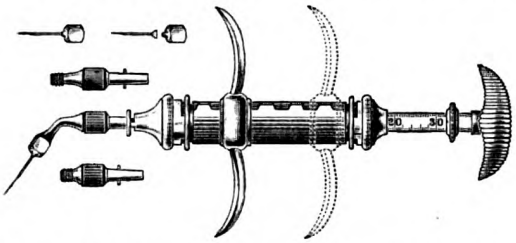
VOYAGE D'ÉTUDES MÉDICALES.—The second Voyage d'Études Médicales of the season of 1912 will take place from Sept. 1st to 14th under the presidency of Professor Landouzy, when the following route will be observed: La Motte-Beuvron (sanatorium), La Roche-Posay, Néris, Evaux, La Bourboule, Mont-Dore, Saint-Nectaire, Vic-sur-Cère and Le Lioran (climatic stations), Royat, Durtol (sanatorium), Chatel-Guyon, Vichy, Bourbon-l'Archambault, Bourbon-Lancy, St. Honoré-les-Bains, Pougues. For further information application should be made to Dr. Carron de la Carrière, 2, Rue Lincoln, or to Dr. Jouaust, 4, Rue Frédéric-Bastiat, Paris.

CHELSEA CLINICAL SOCIETY: ANNUAL DINNER.—This society held its annual dinner at the Hotel Richelieu on March 20th, the day after the conclusion of its annual clinical debate. The President, Dr. J. A. Mansell Moullin, was in the chair, and the guest of the evening was Professor Einthoven, of Leyden, to whose paper on the Electrocardiogram (published on p. 853 of our present issue), many complimentary references were made by the speakers. The chairman, in proposing the toast of the society, congratulated it on having now, in its fifteenth year, a suitable meeting-place in the medical school of St. George's Hospital. This had added much to the success of the meetings, and the members were very grateful to the hospital staff for lending the rooms. Dr. T. B. Hyslop responded in a humorous speech, and spoke of the increasing use and success of the society. The health of the guests was proposed by Dr. T. W. Parkinson, who referred to the international and non-political nature of the brotherhood of science. He said that the medical profession, although it practised conservative surgery, prescribed a liberal diet, performed radical operations, and held socialistic theories of friendship, had no other politics. Professor Einthoven, in his reply, paid a graceful tribute to the society, and remarked that the electrocardiogram had at least demonstrated the good-heartedness of English medical men. Dr. A. Waller, who was called upon for a speech, said that he had never dreamt of the practical possibilities of the instrument designed by Professor Einthoven. Dr. R. S. Trevor, dean of St. George's Hospital Medical School, the Mayor of Chelsea, and Professor Hugo Marcus, of Buenos Aires, also responded for the visitors, and the toast of the President and officers of the society was entrusted to Dr. Campbell Boyd. Dr. Mansell Moullin (president) and Dr. G. A. Simmons (treasurer) replied, and a successful evening was shortly afterwards brought to a close.

New Inventions.

DENTAL HYPODERMIC SYRINGE.

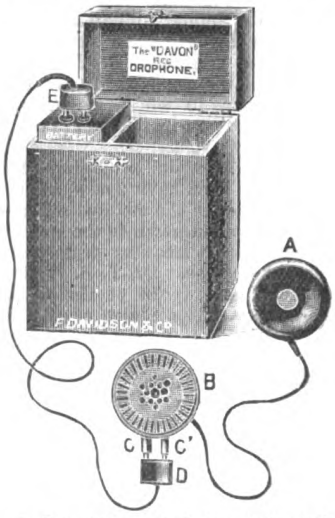
Messrs. Burroughs, Wellcome, and Co., Snow Hill Buildings, London, E C., have made an improved pattern of their dental hypodermic syringe, which has been strengthened and simplified in some of its parts. The syringe shown in the illustration is made entirely of metal, is easily taken apart for cleaning and sterilising, and as easily put together again. No packing is required round the piston, which consists of a solid plain metal plunger, ground to fit the barrel accurately. The barrel, cap, nozzle, and needle attachment are locked together by a simple modified form of bayonet catch, which



does away with screws, washers, and other parts easily damaged or lost. The finger-grip can be fixed at any point on the barrel, and there is a screw on the plunger rod which regulates the amount of fluid injected. Unmounted needles are used, and the metal case in which the instrument is packed forms a sterilising tray. The qualities which the manufacturers claim for this syringe—namely, efficiency, durability, stability, and convenience—are well substantiated in actual use.

THE "DAVON" OROPHONE.

THIS electrical aid has a different tone to any other at present on the market. This in itself will make it of value to cases which can be aided by this class of instrument, as a certain proportion of patients will prefer it to any other design. It will not, however, suit such a wide range of deaf cases as some of the appliances already known to us. With this instrument, after the ear has been educated to it, the suitable



A, Receiver. B, Transmitter. C, C', Terminals of the transmitter into which the connecting plug D is inserted; these terminals are of different size, so that the plug can only be inserted in the right manner. D, Connecting plug to transmitter. E, Connecting plug to battery.

patient will be able to pick up speech from a distance, as, although the instrument is not a loud one, the transmitter diaphragm is not "damped" in any manner. The buzzing present in so many "electrical aids" is abolished in the "Orophone," which would serve as a preparatory instrument until a more powerful one could be used. The transmitter has no tab to fasten it on to the clothing, or any means of being attached to the battery, so that the battery may be used as a pedestal or support. The receiver ear-cap is unnecessarily large for the size of the diaphragm used, and the diaphragm is not adjustable, while the battery is too large to be carried in the pocket. The flexible cords are good and well fastened off, so that the mechanical strain comes on the covering and not on the conductor; but the receiver cord is too long, and the method of fastening the cord on to the transmitter entails taking the transmitter to pieces to put on a new cord. The instrument may not prove very economical, because there is no switch in circuit to use when not listening to any sound, while the current consumption is not low. It has been tried on a number of cases and most patients could hear distinctly better with it than without it. The instrument is made by Messrs. F. Davidson and Co., 29, Great Portland-street, London, W.

A NEW PORTABLE OPERATING TABLE.

THIS table, recently made to my design, consists throughout of finest seamless steel tubing, except the hinged joints, which are of solid brass, and the ratchets, which are of pressed steel. The table is absolutely rigid, very strong, and weighs a little over 30 lb. It can be unpacked, set out, and repacked in a few seconds. When closed it measures $39 \times 21 \times 3\frac{1}{2}$ in. (Fig. 1), when open it is $71 \times 36 \times 21$ in. (Fig. 2), but it can be manufactured any less height than 3 ft. The head legs are slanted, giving a large base, and suiting the Trendelenburg and allied positions; all the legs are fitted with solid rubber feet. The illustrations show the table closed and open, with the long foot extension dropped, but it can be fixed in any of the positions required in modern surgery. Lithotomy uprights and straps are provided, and an arm rest and instrument trays which simply catch on to the side of

FIG. 1.

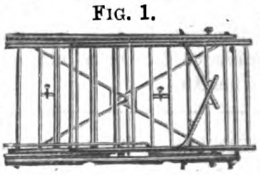


FIG. 2.

the table are added. The difficulty met with, even in operating theatre tables, of over-extending the arm, as required in dissection of the axilla, has been met by a detachable rotatable bar to which the arm may be attached and held horizontally at any angle. In addition an upright bar can be fitted on to any of the legs, or at any point on the upper horizontal bars, on which may be hung a lamp, an infusion apparatus, and so on; this also carries a candle-socket. All the tube joints are welded and rounded. The ratchets of the head and foot extensions are detachable and fitted with special sockets preventing any save intentional movements. The table is nickel-plated throughout, but can be enamelled if preferred. For travelling purposes a canvas bag, or a light tin case, or a wooden case, which becomes an instrument table if required, have been provided by the makers, Messrs. James Gibbons, of Wolverhampton.

Wolverhampton. C. A. STIDSTON, M.D. Lond.

THE LANCET.

LONDON: SATURDAY, MARCH 30, 1912.

Coal Smoke Abatement.

MUCH good work has been done in the direction of abating the smoke nuisance since the question was asked in THE LANCET some 17 years ago, "Is the Smoke Nuisances Act properly enforced?" That question received an emphatically negative answer from us, with a positive proof that the provisions of the Act were practically ignored by our public health authorities, the evidence of whose wanton disregard was patent on all sides. Three years later, however, there were signs of the question receiving serious attention, for in 1898 the Coal Smoke Abatement Society was formed under the guidance of its first and present President, Sir WILLIAM RICHMOND, with Dr. HAROLD DES VŒUX, the treasurer, as one of its leading spirits. The society has since done excellent work by prosecuting practical inquiries to show the extent to which nuisances existed and by pointing the way to remedy. From time to time we have published in our columns the results of the practical investigations referred to; the opinion of sanitary authorities has thereby been stimulated, and at last the public is realising that the evil is real and one that should be prevented. So much progress has been made in the comparatively short time during which the Coal Smoke Abatement Society has existed that it feels justified in reporting that "the result of the modern crusade is already apparent in a decrease of the smoke-laden fogs which a generation ago made existence in the metropolis a burden for several months in each year." The society has set itself a great task, but the results are certainly encouraging.

There is much more to be done, however, as was shown in the report from THE LANCET Laboratory which appeared recently in our columns[1] as to the enormous amount of soot which annually falls upon the metropolitan area. When it is shown that from 60,000 to 70,000 tons of soot are showered upon our public buildings and streets in the metropolitan area every year, it is clear that not only is there a sheer wastage of fuel going on, but also an output of products, solid and gaseous, which are a menace to the public health and a source of destruction to property. The metropolis is not alone in committing this offence, for recently we have received a very carefully compiled and interesting account of the smoke scourge in Leeds,[2] in which the authors record that a comparison of THE LANCET Laboratory figures in regard to London shows on the whole a very ominous agreement with the results obtained in Leeds. For example, the annual soot deposit from Leeds rain varies from 539 tons per square mile to 25 tons; in London from 426 tons to 158 tons, the mean for the Leeds area being 220 tons, that of the London area 260 tons per square mile. Again, the amount of sulphuric acid in the London city area was about 69 tons per square mile, whilst in Leeds the average for the four city stations was 65 tons per square mile. It is rare indeed that the air, even in the country, can be shown to be free from atmospheric contamination due to smoke. The importance of these inquiries is obvious when health statistics in relation to smoke-laden places show without doubt that coal dust, smoke, and soot increase the death-rate from acute lung diseases. The great damage inflicted upon vegetation, upon the fabrics of our buildings, and the stores of our merchandise has also to be sorrowfully remembered.

Considerations of the foregoing description make the International Smoke Abatement Exhibition, held this week under the auspices of the Coal Smoke Abatement Society at the Royal Agricultural Hall, of special interest. It is clear, at all events, that a movement good from both a health and economic point of view has come into real being. "Gas companies and electricity supply undertakings," we are told—and a personal inspection of the exhibits which we have made shows that it is true—"vie with each other in bringing before the notice of the community the special advantages which their systems of cooking and heating offer to the householder." Natural and artificial smokeless fuels are being constantly pressed upon the public, and in various realms of industry it is generally recognised that scientific principles can now be so applied to the production of power that in most cases, at all events, it is in a pecuniary sense advantageous to avoid the emission of unreasonable volumes of smoke. The remarkable reduction which has taken place in factory and domestic smoke is a sign clear enough to encourage the hope that a clean and pure air is within a measurable distance. We congratulate the Coal Smoke Abatement Society on the excellent progress which it is making, and we are glad that we have been able to contribute to this success by our own practical investigations, as well as by the publicity which from time to time we have given to the urgent need there is for removing a reproach from our midst.

The Treatment of Leprosy by Nastin.

FOR many years search has been made to discover a specific for leprosy, a remedy which might be relied upon to act in the majority of cases as mercury does in syphilis or quinine in malaria. Though various drugs have been brought forward at one period or another as cures for leprosy, none of them have stood the test of time, and each in turn after a brief period of popularity has fallen into disfavour. Some cases of the disease improve unaccountably for a time without having been submitted to any method of treatment, and it is a well-recognised fact that the mere removal of a leper from his squalid and filthy home to the better hygienic surroundings of a hospital or asylum often produces, for a time at least, a marked improvement in his state of health. Leprosy in many instances follows an irregular or erratic

[1] The Sootfall of London: Its Amount, Quality, and Effects. THE LANCET, Jan. 6th, 1912, p. 47.
[2] Smoke, a Study of Town Air. By Julius B. Cohen, Ph.D., B.Sc., F.R.S., and Arthur G. Ruston, B.A., B.Sc. London: Edward Arnold. 1912. Pp. 88. Price 5s. net.

course, the progress of the disease being apparently arrested without any obvious cause, and the literature of leprosy furnishes many examples in which nature entirely unaided by drugs has brought about what may be regarded as an approximation to a cure. When with his knowledge and consent a leprous patient is placed under treatment by a new remedy his mental attitude seems to be stimulated by the renewed hope of recovery inspired by the new drug, and he is seemingly apt to exaggerate unconsciously his own feelings and to express himself as being much benefited, at the same time devoting himself to his work with greater zest and alacrity. In the circumstances it is obvious that there are peculiar difficulties to be encountered in estimating the precise value of any method of treatment for leprosy, and it is admitted that errors in judgment are particularly liable to arise in this connexion.

Few modes of treatment brought forward in recent years for leprosy have raised such hopeful anticipations at their introduction as did nastin, which was introduced some six or seven years ago by Professor G. DEYCKE, now of Hamburg, and formerly of the Turkish Government Medical Service. At the February meeting of the Society of Tropical Medicine in London Professor DEYCKE read a paper on the treatment of leprosy by his method and the results so far obtained by it. In the statistics which he brought forward he dealt with 529 cases which had been treated by 69 different medical men in various parts of the world. He stated that he had excluded from his tables any cases treated personally by himself for the reason that the fate of a new remedy should rest as far as possible in the field of general practice, and not in the hands of the discoverer. Of the 529 cases, 13 were reported as cured, 34 nearly cured, 131 considerably improved, and 154 as improved—a total of 332, or 62·76 per cent., in which beneficial results were attributed to the method of treatment. The improvement is said to have been almost equally shared by the three forms of the disease—the nodular, the anæsthetic, and the mixed, and Professor DEYCKE has pointed out that he has never in his published works spoken about the "cure" of leprosy by nastin, but always of "the arrest of the disease" or "the improvement in the symptoms and the general health of the patient." He holds it advisable in special cases to speak of nothing more than "temporary freedom from the presence of B. lepræ." But even with these restrictions he claims that his results are very satisfactory, and he repeats what he maintained at the Bergen Congress on Leprosy in 1909, that "the nastin treatment, if consistently and rationally applied for a sufficient time, produces in a large percentage of cases of leprosy more or less extensive improvement in the 'leprous systems' and in the general health of the patients." He also emphasises the fact that he attaches less importance to the "qualitative" results of the treatment than to the "quantitative," contending that he is justified in the assertion that nastin, though no "wonder-remedy," has proved "quantitatively" equal to the claims which he had put forward on its behalf.

When nastin was first brought forward some difficulty was experienced in finding sufficient opportunities for trying its effect on any large scale, and repeated applications were made by Professor DEYCKE and his supporters to the British authorities to have the remedy tested in one or other of the colonies where leprosy was prevalent. Ultimately the Colonial Office agreed to allow Professor DEYCKE to test nastin in the public leper asylum at Mahaica in British Guiana, the work to be carried out in coöperation with the colonial medical officers. During a period of six months Professor DEYCKE conducted the treatment by his method, and at the same time instructed the Government medical men in the details which were to be carried out after his departure, so that there was no question of the treatment being administered otherwise than according to its originator's own method. Last year Dr. K. S. WISE, the Government bacteriologist (who is also, we understand, the director of public health) for British Guiana, presented a report to the Colonial Office showing the results achieved in the 135 lepers who had received the treatment between December, 1908, and September, 1910.[1] Dr. WISE reported that a few seemed to have improved considerably, that some were worse, and that the majority remained *in statu quo;* he added that since the favourable results were so few a longer and wider experience could alone determine whether the successful cases were merely instances of natural improvement irrespective of the nastin treatment, or were, on the other hand, really due to the action of that remedy alone. In continuation of Dr. WISE'S observations the Colonial Office has recently issued a "Further Report on the Nastin and Benzoyl Chloride Treatment of Leprosy at the Mahaica Leper Asylum from September, 1910, to September, 1911," by Dr. E. P. MINETT, assistant bacteriologist for British Guiana. This officer had taken Dr. WISE'S place during the latter's absence on long leave in Europe. The report deals with three groups of cases, 24 patients being treated with nastin, 71 with benzoyl chloride, and 8 receiving no medicinal treatment at all. Dr. MINETT appears to have no hesitation in arriving at his conclusions. He regards nastin as being apparently of little value in cases of leprosy, and the subcutaneous injection of benzoyl chloride in sterilised oleum petrolatum he looks upon as of doubtful utility, though in the figures which he presents the latter shows a slightly higher percentage of improvement in the cases treated with it, as compared with the former. But in his opinion benzoyl chloride in petroleum oil is extremely valuable as a nasal spray or as a paint for application to ulcerating surfaces; it quickly renders the discharge free from the presence of bacilli, and he strongly recommends its regular use for this purpose in all leper asylums. The so-called destruction of the bacilli is, in Dr. MINETT'S view, of limited value as an indication of the effects of treatment.

The results obtained in the leper asylum at Mahaica appear to be very different from those reported to Professor DEYCKE by the 69 medical practitioners already mentioned. The British Guiana cases were excluded from Professor DEYCKE'S statistics, partly because he had himself treated some of them for six months, but mainly because, as he stated in his paper, he had no figures as to the actual results; he adds, however, that he knew that a number of the cases had been discharged from the asylum, bacteriological

[1] THE LANCET, July 22nd, 1911, p. 237.

examination having proved the absence of B. lepræ in these instances. But it appears to us the figures were available if wanted, for the reports by Dr. WISE and Dr. MINETT had already been published before Professor DEYCKE'S paper was read. It is, of course, possible that selection of cases for the nastin treatment might have had an important influence on the statistics. For if early cases were selected by the majority of the 69 practitioners satisfactory results of treatment would be more likely to be obtained than if advanced cases had been chosen. We have it on Professor DEYCKE'S authority that a good number of the lepers treated by nastin at the Mahaica Asylum were in an extremely bad condition as regards the disease; and it is, therefore, possible that such cases would not readily derive much benefit from the nastin treatment. With this conflicting evidence before us it is not easy to arrive at a definite conclusion, but in the circumstances we think we are justified in saying that up to the present the evidence put forward in favour of nastin is hardly convincing enough to lead to its general acceptance. Further observation and experience seem to be required before a correct opinion regarding it can be reached.

Annotations.

"Ne quid nimis."

THE COAL STRIKE.

BY no one is the approach of misery among the poor more easily detected than by the medical man, and now the signs have become very obvious to those whose daily work it is to superintend our public health or administer our great charities. It is very difficult, therefore, to contemplate without keen anxiety the outlook that this disastrous coal strike may yet last some weeks—or that, at any rate, it may be some weeks before a general return to work takes place. But that is the prospect which has to be faced. The calmness and order which have so far characterised the behaviour of the public under cruel trial is a thing of which we may all, as a people, be justly proud. The necessary self-control is putting a severe strain upon thousands of persons, as all our readers know, but the attitude must be maintained, and those of us who can help their weaker brethren in any of the sad concomitants of a national tragedy will find in such actions the bravest support for themselves.

MURDER BY POISON.

TRIALS for murder by poison are of special interest, both to the medical man and to the student of crime from the legal point of view. Of necessity a murder by poison is always premeditated and practically always one carried out in secret. Evidence calculated to bring the crime home to the accused is therefore, as a rule, purely circumstantial and dependent upon problems of chemical analysis and a knowledge of pathology and of differential clinical diagnosis. Medical murderers are, we are thankful to say, few in number, but naturally enough when a member of the medical profession does sink so low as to commit murder he chooses poison as the means of crime. He can obtain it without suspicion, and also in many cases has opportunities for administration which are denied to laymen. Three of the most notable trials for murder by poison in the last century were those of Lamson, Pritchard, and Palmer, all three medical men. The trial of the last-named, a copy of the proceedings at which now lies before us, created a great sensation at the time, and is still a leading case in treatises on medical jurisprudence as to strychnine poisoning.[1] The medical points raised in the trial were many and various, among the chief being the conflict of evidence as to whether the symptoms from which Cook suffered were indicative of strychnine poisoning, tetanus, "idiopathic" or traumatic, or, it is surprising to read at the present day, angina pectoris. Again, no strychnine was found in the body after death by the Crown analysts, although various analysts called by the defence testified that there should have been no difficulty in finding it, had it been administered so as to cause death. Mr. Knott has contributed an interesting introduction, giving a *précis* of the Attorney-General's opening speech for the Crown. He has also printed two appendices, of which the second gives an account of the judges (there were three) and the counsel engaged in the trial, while Appendix I. is a reprint of an astonishing pamphlet which was circulated after the trial, addressed to Lord Chief Justice Campbell, and purporting to be written by the Rev. Thomas Palmer, brother of the prisoner. Thomas Palmer denied the authorship, and the letter is attributed "to a blackguard barrister." That William Palmer was guilty, not only of the murder of Cook but of several other murders for which he was not tried, there can be no reasonable doubt, and the proceedings at the trial form a notable example of careful and judicial reasoning of interest to every medical man. Mr. Knott makes no mention in his introduction of a story which has often been told, but which is worth recalling none the less. It is said that after the conviction of Palmer the inhabitants of Rugeley, being distressed at the evil reputation which their town had obtained, petitioned the then Prime Minister for leave to change the name of the town. They were uncertain by what new name to call it, and the Prime Minister kindly suggested that it should bear his own name. The deputation were much flattered until one of them suddenly remembered that the Minister's name was Palmerston. So Rugeley the town remained. Is there any basis of fact for this story?

EXPERIMENTS UPON LIFE WITHOUT MICROBES.

IN practically all vertebrates the alimentary canal contains very large numbers of bacteria, some of which appear to serve a useful purpose and therefore to be in a sense symbiotic. It has long been a matter of debate as to whether life is possible without these organisms, and experiments have hitherto given results which were by no means conclusive. Some interesting observations are recorded upon this subject in the *Annales de l'Institut Pasteur* of Feb. 25th by M. Michel Cohendy. Metchnikoff has shown that some invertebrates are bacteria-free. His researches demonstrated the aseptic character of the intestine of the scorpion and that of several species of mites. Certain helminthes, parasitic in man, such as young round worms, have also been found to be bacteria-free. Wollman has been able to rear the larvæ of flies (Lucilia Cæsar and Caliphora vomitoria) under sterile conditions. Experiments upon vertebrates have been attended by great technical difficulties and have given discordant results. Schottelius has devoted several years to the investigation of this question, using the hen's egg. His results have led him to the conclusion that life is impossible without microbes. Mme. Metchnikoff succeeded in raising under sterile conditions a series of tadpoles, but they were cachectic and puny. Nuttall and Thierfelder endeavoured to rear fœtal guinea-pigs removed

[1] Notable English Trials: William Palmer. Edited by George H. Knott. Edinburgh and London: William Hodge and Co. Price 5s. net. Pp. 320.

by Cæsarean section; the animals increased in weight normally, but the experiments had to be interrupted on the tenth day owing to technical difficulties. M. Cohendy has carried out observations upon the development of the chick under sterile conditions partly in Professor Schottelius's laboratory at Freiburg, partly at the Pasteur Institute in Professor Metchnikoff's laboratory. He has overcome the technical difficulties encountered by previous workers by devising ingenious apparatus, the first small, the second larger, enabling his observations to be prolonged. He has taken care to control his results by rearing chicks under precisely similar conditions, except in regard to the sterile nature of their food, and also by rearing others under normal conditions outside his apparatus. He has found that in all points except one the chickens raised under sterile conditions were similar to the controls, the only difference being in regard to their digestive functions. The appetite of the sterile animals is greater than that of the others, and their dejecta are more frequent and more abundant. The development in both was equal, and the sterile animals were at least as robust as the controls, although in some instances neither were as heavy as those reared outside the apparatus, this being due probably to the more confined space in which they were placed and to the other conditions of the experiment. M. Cohendy found also that the sterile chickens presented a very great resistance to death by cold, damp, hunger, and thirst. Those of them allowed to continue their life under ordinary conditions after a time of sterile life developed into well-grown adults. M. Cohendy concludes that life under sterile conditions is possible, and that it does not involve any disadvantages for the organism. At the same time he points out that his experiments show that though the intestinal flora are not indispensable they are yet utilised, since apparently the sterile animals require more food and digest it less completely than the normal ones. These results confirm those of Nuttall and Thierfelder, who found that cellulose was not digested by their sterile animals. The fact that these sterile chicks grow normally after the end of the experiment, although their intestines rapidly develop an abundant bacterial flora, suggests that the preparation for the struggle against these microbes is hereditary, and not the result of individually developed immunity. Professor Metchnikoff, in collaboration with four of his pupils, has obtained similar results with Pteropus medius. These observations are of far-reaching interest and merit careful notice.

THE CONSTITUENTS OF BUTTER.

IN THE LANCET of March 16th, p. 751, an account was given of a case heard at the Tower Bridge police court, the subject matter of which arose out of the alleged use of milk powder for the adulteration of butter. On that occasion it was a point at issue whether the milk powder found upon the defendant's premises was intended to be added to the butter which they manufactured, and the finding of the magistrate apparently did not deal decisively with the question whether the use of it, if proved, would constitute an offence under Section 3 of the Butter and Margarine Act, 1907, when he dismissed the case with £40 costs against the Board of Agriculture. In a case recently before Mr. Garrett, however, at the South-Western court, the intended use of the milk powder was not disputed, and evidence was given on both sides as to the desirability of its being employed, as, indeed, was also done before Mr. Rose. It was contended by Mr. MacMorran, K.C., for the defence that the use of milk powder in blending butter from various sources was for the purpose of promoting uniformity of texture, flavour, and colour, and not in order that the article sold might be cheaper to produce than butter to which no milk powder had been added; and that butter was not the less butter after the addition of 1 per cent. of milk powder, in itself a wholesome article of food. Mr. Garrett, in giving his decision, appears to have held that it is essential to butter that it should be churned direct from milk and cream, and that the addition of milk powder containing no butter fat diminished the proportion of butter fat in the compound obtained in such a manner as to constitute adulteration. He did not accept the view that as long as the constituents of butter were present in due proportion in the article produced it was unadulterated butter. After the learned magistrate had imposed a fine of £5, a discussion took place upon the question of costs, which on the side of the Board of Agriculture, the prosecutors, were stated to amount to about £200, and 80 guineas were allowed as costs. It is to be regretted that heavy expenses of this sort should have to be incurred either by the Board of Agriculture or by manufacturers in order to settle in an individual case what constitutes an offence against an Act of Parliament, where it is a matter as to which doubt may reasonably arise. At present, at any rate, Mr. Garrett's decision is one which does not bind, and need not influence, other magistrates who may come to a different conclusion upon similar facts. The preparation of food for the market is a matter which every year produces fresh developments, and mechanical and chemical science is called in aid in increasing degree. The legitimacy of interference with pre-established standards is often doubtful, and cases may arise where it is to the public interest that such interference should be sanctioned or condemned decisively, and it is suggested that it should be possible on such occasions to obtain a regulation, framed by the Government department interested, laying down a definite standard with regard to the matter in doubt. Such a regulation would be based upon the advice of experts guided by expert evidence in making inquiry. It must be remembered that a magistrate is an expert in deciding questions of law; as to questions of scientific fact he is a layman, deciding as such between the conflicting expert opinions.

IONISATION IN RINGWORM OF THE SCALP.

IN the treatment of ringworm of the scalp ordinary topical applications fail because they do not penetrate sufficiently deeply into the hair follicles. The X rays have proved a much more efficient remedy, but are open to the objection that the alopecia which they produce is sometimes permanent. In the *Glasgow Medical Journal* for February Mr. J. R. Riddell estimated the frequency of this occurrence as 2 per cent. of the cases treated, and therefore recommends ionisation, which overcomes the difficulty of penetration. The following technique has given him good results. The head is shaved or the hair cropped short all over. An aqueous 1 per cent. solution of mercuric chloride or iodine (dissolved with the aid of potassium iodide) is rubbed well into the affected parts. Folds of lint (10 to 16 ply) are soaked in the solution and applied evenly to the surface. Over this the electrode is placed and secured by a few turns of bandage. The lint should overlap the diseased area. The electrode may be made of any convenient metal. Mr. Riddell most frequently uses copper gauze, as it is pliable and easily adapted to the surface. It should be large enough to cover the diseased area, and the contact between the head and the lint and between the lint and the electrode should be of equal pressure all over. If there be any irregularity, so that over a small area the contact between the lint and the scalp is much better than elsewhere, the current will concentrate on that point, possibly to such an extent that a slough will be produced. Short of this there may be so much irritation that the treatment has

to be suspended for a week or more. If a public supply of electricity is available this may be used; if not, a battery of 20 or 30 cells. One pole of the supply is attached to the electrode on the head; the other is connected to a water bath in which the child's arm or foot is immersed, or to a large well-moistened pad which may be bound to the arm or leg. The current must not be turned on or increased too quickly. If it is the child will feel pain or disagreeable sensations, such as giddiness, and become restive, so that a prolonged sitting is impossible and only a weak current will be tolerated. The child must be secured so that he cannot suddenly break the circuit, as by taking the limb out of the water. If he does, he will experience a shock and not again willingly submit to the treatment. The current is slowly turned on and gradually increased until the subject begins to feel slight warmth in the scalp. After a few minutes it will be found the current can be increased without discomfort. It should be increased as much as possible short of discomfort. When the area under treatment is large a child usually allows 15 to 20 milliampères to be used. Each sitting should be as prolonged as possible. Mr. Riddell aims at from 40 to 50 minutes, as one sitting of 45 minutes is better than three of 15 minutes. The more prolonged the sitting the deeper will the ions penetrate. The pads should be kept thoroughly wet; at the end of the sitting the current should be turned slowly off. The treatment should be repeated two or three times a week. It is well to have the head washed daily or every other day with an antiseptic, such as the sulphur, naphthol, and green-soap mixture commonly prescribed. If the treatment makes the scalp irritable or scaly a mild antiseptic oil may be used between the sittings, but it must be thoroughly removed before ionisation. Mr. Riddell has found the treatment certain, rapid, and safe. The average number of long sittings required for cure was nine.

THE ART OF MEDICAL PRESCRIBING.

A SHORT article written by "A Retired Hospital Physician" recently appeared in the *Westminster Gazette* under the title "On Decay in the Art of Medical Prescribing." The writer stated that his main design was to prove that if medical men are to write sound and logical prescriptions they must be properly trained to do so; and he further maintained that there was a gradual decay in the art of prescribing, which had been going on for years, and was the natural result of defective teaching. Doubtless in the days of the apprenticed pupil a sound knowledge of the compounding of drugs was obtained, for to quote the words of the article, "all around him were the weapons of his future warfare; he saw, he handled, he weighed." There is much truth in the points that this writer has made, for too much stress is laid to-day on the diagnosis of medical cases and too little on the details of the treatment, especially in regard to the employment of drugs. There is a matter which he did not happen to mention, and it is one which hospital physicians would do well to caution students concerning. The free use which is made of a hospital pharmacopœia in which the dosage and combination of drugs are obscured under the title of "mistura" or "haustus" is dangerous. The student becomes so accustomed to the sounds of the words "mistura gentianæ alkalina" or "haustus albus" that he forgets the actual constituents of those preparations, and when asked to dictate similar prescriptions is frequently at a loss. We believe also, although we are quite prepared to have the opinion challenged, that the constant compounding of medicines in general practice according to the total quantities of drugs in a 6- or 8-ounce bottle tends to less accuracy than when the details of a single dose are set down, so that the exact quantity of each constituent taken by the patient at each dose is borne in mind. The "Retired Hospital Physician" also referred to the manufacture and sale of compound medicines, which certainly save "the busy practitioner from the laborious pain of thinking for himself," but it must be allowed that many of them are good preparations made up in a convenient and palatable form. In a very interesting article, the writer has omitted to state that the medical student has to pass fairly stringent examinations in pharmacy and materia medica, and this was not the case in every medical curriculum in mid-Victorian days.

A SEVENTEENTH CENTURY PIONEER OF ANTISEPTIC SURGERY.

THE Honourable W. R. Riddell, Justice in the King's Bench Division, High Court of Justice for Ontario, Canada, in the *New York Medical Journal* of March 2nd, under the title of "A Seventeenth Century Surgeon and His Fee," gives us the charge to the jury delivered at the Guildhall, London, on May 4th, 1687 (3 Jac. II.), by Sir Thomas Street, Knt., Justice of the Common Bench, in the case of Randall *v.* Sir Thomas Powis, Knt., a document in many respects of surpassing interest to the medical profession. The charge shows without doubt that antiseptic surgery, like so many other of our modern discoveries, was anticipated in the seventeenth century, not only in matters of practice, but also as regards the underlying hypothesis—now a demonstrable fact, thanks to Lister, whose merit is in no way encroached on by this anticipation. For, as we have so often said, it is he who compels the world's attention to, and acceptance of, a truth and enforces or renders possible its application, who confers on mankind that benefit which is the measure of merit. Sir Thomas Street's charge sets forth that the defendant, having been wounded in the arm, and being "suddenly dejected into extreme debility and danger ..... employed a surgeon who treated him in a manner recommended by his art and mystery with topical applications." But "the wound did not improve, and the defendant, despairing to find ease or benefit by the fruitless continuance of this chirurgery, and fearing the speedy invasion of a gangraene, consulted the plaintiff." Then follows this statement, remarkable indeed in the year 1687: "This new surgeon enjoined the immediate removal of all emplasters and other topical applications, and he washed the wound carefully from time to time with fair clean water, covered it with a clean soft linen cloth, and cleansed it once a day from pus and other impurities." We are further told that "the wound hath gotten well and the surgeon sues the Knight for his reward." After a discussion of the professional ethics which, while forbidding a physician to sue for his honoraria, permit surgeons, who "are of an inferior degree amongst the professors of the healing art," to "demand their fees as of right," and a learned disquisition on the treatment of wounds according to the orthodox surgery of the day, the remarkable prescience of the surgeon, Randall, is set forth as follows: "Now the plaintiff did naught save wash and tend the wound; he used no sympathetic powder or sympathetic unguent and he giveth his reason. ..... He saith that the pus which all others admire and desire as showing that Nature hath armed herself for the fight is not to be desired, but that it is itself an impurity which should be avoided—that it hindreth the cure and contendeth against the *vis medicatrix naturæ*. He hath even in his mind some crotchet that pus is engendered by some small animal or plant, some bug or gnat or beettle or fungus belike, though he saith openly that he cannot prove the existence of such creatures. This however he contendeth is

because his glasses do not magnify sufficiently to enable him to see them. And he meaneth not the glasses or spectacles for weak or aged eyes; but the microscope which hath a rare and admirable faculty of making small things appear large. ..... He saith forsooth that the true treatment is to keep all extraneous matter away from the wound and even the air which he imagineth to be full of his bugs and gnats and beetles." Moreover, Randall's views, even then, were apparently not unique, for the charge adds: "Yet he sayeth that his method of cure is well known to the profession, though that is denied by other surgeons." We regret to say that this pioneer confessor of antiseptic surgery lost his case. The summing-up was dead against him: "That is the question ye are to try, and if ye find that his mode of cure is acknowledged in his profession, ye will give him your verdict; and if otherwise, not. And it is naught that the Knight hath been cured. It may be that the powerful medicaments applied by his first attendant but succeeded in making their power felt after the plaintiff was consulted. Ye may indeed think that if the plaintiff is right in his contention that it was but the unassisted *vis medicatrix naturæ* which effected the cure, all the credit for the cure should be given to Dame Nature herself and the plaintiff deserveth none—having no credit, neither should he be given cash." Niemeyer and nihilistic therapy would evidently have had short shrift in 1687!

THE REPORTING OF VENEREAL DISEASES IN NEW YORK.

Mr. Ernest J. Lederle, Ph.D., Commissioner of Health of the City of New York, informs us that the Board of Health of that city has recently taken a bold, and it must be admitted a logical, step forward in the matter of bringing venereal diseases under administrative control. On Feb. 20th the board adopted, and the advisory board of the department, comprising a number of the most eminent medical men of the city, approved, resolutions "requiring" superintendents or other officers in charge of public institutions, such as hospitals, dispensaries, clinics, charitable and correctional institutions, including all institutions supported wholly or partly by voluntary contributions, to report promptly to the Department of Health the name, sex, age, address, nationality, race, and marital state of every patient under observation suffering from any stage of syphilis, chancroid, or gonorrhœal infection; and "requesting" private practitioners to furnish similar information (but excluding the name and address) with regard to their private patients so suffering. All information so obtained is to be regarded as confidential, not to be accessible to the public, and not a matter of public record. In return for the service the board will undertake on request to make without charge for medical men so reporting the Wassermann and Noguchi tests for the diagnosis of syphilis and to examine for spirochætæ specimens submitted to them. The possession by the sanitary authorities of information concerning all communicable diseases is an indispensable requisite to their administrative control and ultimate extermination. Venereal diseases are more disastrous in their consequences to the race, and are more dangerous to the community at large in proportion to their prevalence among the ignorant and those whose financial position prevents their taking adequate means of cure. Where the economic status is such that the sufferers depend for the subsistence of themselves and their dependents entirely on continued personal toil, they must in numberless ways assist in the spread of infection. The obvious conclusion is that the venereal diseases, more than any other kind of disease, call for notification and control in the interests of the community and the race. When, however, it is proposed to extend the sanitary regulations so as to include compulsory notification of this class of disease, the gravest difficulties present themselves. These arise almost entirely from the stigma of moral turpitude with which these diseases have long been associated in the public mind, thus entailing serious social and economic consequences on any breach of the confidential relations that properly exist between medical attendant and patient. On the other hand, it must be remembered that the injury caused by one case due to a breach of morality spreads in ever-widening circles involving innocent victims in every direction, who in their turn, and entirely without any fault of their own, may become unwitting and unwilling foci. Between those, then, who regard medicine almost exclusively from the point of view of a social science, and those who regard it as almost entirely a personal and confidential relation between doctor and patient, these diseases form, as it were, the last ditch, where compromise becomes no longer possible, and the battle must be fought out to the end. The difficulties of the problem are indubitable, and the working of the New York experiment will be watched with keen and sympathetic interest by public health authorities all the world over. It is greatly to be desired that some term should be substituted for the present ones, to which the idea of moral obliquity attaches; for those who are innocently suffering the consequences entailed by no moral lapse of their own may outnumber those in whom the disease is the result of their own personal misconduct. The stigma is the first block in the way of willing acceptance of administrative control; but the stigma, though now attaching to all, belongs properly to only some; therefore its removal would seem to be the first essential step towards obtaining that ready acquiescence in administrative control which alone can render it adequately effective in a civilised and free community.

ARE SOME OF THE UNCLASSIFIED FEVERS OF TROPICAL REGIONS RELATED TO YELLOW FEVER?

IN the Mexican province of Yucatan cases of unclassified fevers are sometimes observed by the local medical practitioners, and yellow fever is also not unfrequently present in the same region. Dr. Seidelin, whose name is well known as an investigator of this subject, has sought in Yucatan to discover in the blood of patients suffering from fever of undetermined origin the presence of parasites which might prove to be the cause of such illness. In an article entitled "Notes on Some Blood-parasites in Man and Mammals," which he contributes to the last published number of the *Annals of Tropical Medicine and Parasitology* (Vol. V., No. 4), he mentions that he had found in the blood of a man suffering from unclassified fever at Merida in 1910 certain bodies which he regards as parasites. They were fairly numerous on the fourth day of the fever, but scarce on the eighth day, and entirely absent on the ninth and tenth. They were not unlike the yellow fever bodies, which Dr. Seidelin has named paraplasma flavigenum, though differing from them in certain respects. The symptoms observed in the patient were not precisely those described in typical cases of yellow fever, though they were sufficient to arouse suspicion that the illness might be of that nature. It is known that the clinical characters of yellow fever may vary considerably in certain circumstances, and the clinical picture of the disease in one place may not always be the same in another locality. Dr. Seidelin suggests that yellow fever belongs to a group of fevers produced by blood-inhabiting parasites which may differ, though more or less intimately related to each other. Such differences might perhaps account for the variations in the clinical pictures of yellow fever in one and another

region; and this might also serve as an explanation of some at least of the puzzling points which have arisen in the epidemiology of the disease. Should this suggestion by Dr. Seidelin prove correct the illness of the patient mentioned above might be regarded as belonging to the yellow fever group, and its parasite as another species of the same genus as the yellow fever parasite—the paraplasma flavigenum. To this new species Dr. Seidelin proposes to give the name of paraplasma subflavigenum, and he has deposited a type specimen of it in the collection of the Liverpool School of Tropical Medicine. He had hoped to have met with other cases of the same kind, but he now publishes a summary of this single case, as it presents some points of special interest when considered in connexion with his previous observations respecting the etiology of yellow fever, to which it may be remembered we drew attention in THE LANCET of Jan. 20th. The question whether yellow fever is transmitted to man by one intermediary host alone, the stegomyia fasciata, and whether other members of the yellow fever group may have the same or other convectors, is not dealt with by Dr. Seidelin in his present paper. He has, however, already raised the point that yellow fever may have other transmitting agents than that generally recognised. It has been quite recently suggested also in another quarter that the passage of a parasite through the body of a different insect host than that in which its cycle of development commonly takes place may have the effect of altering or modifying the biological and pathological characters of the parasite and thus give rise to variation in the usual clinical manifestations of the resulting infection in man. To this question, no doubt, Dr. Seidelin and other competent investigators may direct their attention, and in time succeed in furnishing us with a satisfactory conclusion.

THE FEEBLE-MINDED INEBRIATE.

IN a lecture which he delivered recently at University College, Mr. David Heron, of the Francis Galton Eugenics Laboratory, discussed the results obtained by the biometric analysis of the cases dealt with in certified inebriate reformatories since the passing of the Inebriates Act of 1898. It was pointed out that mental defect of a more or less pronounced degree was present in a large majority of these so-called inebriates, that this defect was apparent usually when the individuals were admitted to the reformatories, and that there was only a very slight increase in its amount with age or duration of alcoholism. On the other hand, a very close relationship could be traced between mental defect and the level of education, a character which is largely pre-alcoholic. The inference to be drawn from these facts is obviously that in the cases discussed the mental defect to a very large extent preceded the inebriety. As regards the results of the reformatory treatment, the lecturer referred to the after-history of over 1800 persons committed under the Act, and showed that even within the very brief period that had elapsed after discharge nearly 80 per cent. had returned to their inebriate habits. The Inebriates Act up to the present has been applied mainly to women, and it is the most interesting and significant fact brought out in Mr. Heron's investigation that these women, two-thirds of whom are mentally defective, had not smaller but larger families than sound stocks. Thus it was found that 865 female inebriates had in all 2589 children, while the average completed family was nearly 8. As there is no reason to suppose that these mentally defective women differ in their characteristics from the general run of the feeble-minded, their very high fertility indicates the grave and urgent danger to the community which is involved in the unrestricted procreation of the mentally unfit. This is the most important lesson to be learned from Mr. Heron's very interesting lecture, and the lesson might, perhaps, have been conveyed with more force and clearness if the lecturer had presented his facts as bearing on the problem of feeble-mindedness to which they are really relevant, and had not given to his address the somewhat misleading title, "A Study of Extreme Alcoholism." It introduces needless confusion when a term, which is ordinarily used to mean prolonged and intense poisoning with alcohol, is employed to signify the fact of frequent sojourn in an inebriate reformatory. It is tolerably obvious that the two conditions, so far from being equivalent, are more likely to be mutually exclusive.

THE EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

THE International Congress of Applied Chemistry meets this year in Washington, on Sept. 4th, and in New York, from Sept. 6th to 13th. The work of organisation is proceeding very rapidly, and the preliminary announcements which have reached us indicate a wealth of papers to be read possessing theoretical and practical importance in accordance with the object of the congress, which is the advancement of all applications of chemical science to practical life. The topics to be discussed cover a very wide field. There are over 20 sections, including subsections dealing with analytical chemistry; inorganic chemistry; metallurgy and mining explosives; silicate industries; organic chemistry; coal-tar colours and dye-stuffs; industry and chemistry of sugar; indiarubber and other plastics; fuels and asphaltes; fats, fatty oils, and soaps; paints, drying oils, and varnishes; starch, cellulose, and paper; fermentation; agricultural chemistry; hygiene; pharmaceutical chemistry; bromatology; physiological chemistry and pharmacology; photochemistry; electro-chemistry; physical chemistry; law and legislation affecting chemical industry; and political economy and conservation of natural resources. The programme is eloquent as to the rôle which chemistry is assuming in human affairs, and a position has been reached which shows that efficient training in technological science is rapidly becoming of the utmost importance.

DERMATO-MYOSITIS.

AN interesting case of this rare condition was recently reported by Dr. F. E. Batten[1] at the Neurological Section of the Royal Society of Medicine, the clinical details being supplemented by a full record of the pathological findings at the necropsy and by microscopical examination. The patient was a girl, aged 9 years, who had previously been an inmate of the Metropolitan Hospital under the care of Dr. W. Langdon Brown. When first seen she exhibited erythema of the face, scalp, and extensor surfaces of the limbs, the skin of these regions being swollen, hard, and inelastic, and scaling subsequently ensued. She gradually became stiff and unable to walk, exacerbations occurring in which the muscles were acutely swollen and the skin over them red. As the disease progressed the child emaciated considerably and the muscles generally diminished in size. Movement of nearly all the joints was limited, but the articulations themselves were not involved. Fluid withdrawn from a swollen area of muscle was sterile and showed no special cellular characteristics. There was no eosinophilia, and von Pirquet's and Wassermann's reactions were negative. The patient's temperature never rose above 100° F. except when infection of the urinary tract was present. This finally proved fatal, the child dying after an illness of 15 months. At the necropsy the skin appeared normal to

[1] F. H. Batten: Case of Dermato-myositis in a Child, Proceedings of the Royal Society of Medicine, vol. v., No. 4, Neurological Section, 1912, p. 103.

the naked eye, but it was unusually firm. The liver exhibited a peculiar condition, being studded with small circular, yellowish areas, which could be shelled out from the surrounding tissue. The largest were about ⅛ in. in diameter. Microscopically these were composed of fat. The skin in sections showed atrophy, the epidermis being reduced to a few layers and the papillæ absent in places. The subcutaneous fat was largely replaced by fibrous tissue, and the vessels of the corium were partially occluded, owing to fibrosis of their walls and hyaline change. The muscles showed atrophy of their fibres, especially in the peripheral bundles, and here and there lymphocytic infiltration was visible round the vessels. The nervous system was normal. The course of the affection and the pathological changes alike point to a chronic infective condition, the toxins acting on the skin and muscles principally. In spite of careful examination, however, no parasite was discovered in this instance. Dr. Batten suggests that inoculation of animals may advantageously be carried out in future cases of this disease and may prove more successful than simple culture experiments.

THE SEVENTH INTERNATIONAL CONGRESS ON TUBERCULOSIS.

AT 10 o'clock on Sunday morning, April 14th, there will be a solemn and imposing ceremony at the Capitol in Rome. Their Majesties the King and Queen of Italy will declare open the Seventh International Congress on Tuberculosis. On the previous evening there will be a reception of the members of the congress. Previously, however, to the assembly of the great Congress the International Association will hold a conference from April 11th to the 13th, the sittings taking place on the same premises as the forthcoming congress—namely, at the historic Castle of St. Angelo. Probably the International Committee of the Association of the Medical Press will meet here also, for the members are convoked for April 13th. The sittings of the sections of the actual Congress will commence at nine in the morning of Monday, April 15th. The sections will then be organised and formally opened; but during the four subsequent days will meet in the afternoon, leaving the mornings free. This is a wise arrangement, for it is quite certain that as there is so much to see at Rome the attendance will be very poor at some of the sections if the working hours are made too long. On Saturday, the 20th, the closing ceremony will be held also in the afternoon. The sight-seeing, for which time has been thus provided, will be the more assiduously pursued as the Minister of Public Instruction has graciously conceded to the members of the Congress the right of free entry to all the national monuments of the entire kingdom. This free entry is also accorded to the present International Exhibition of Hygiene, to the Retrospective Exhibition, the Archæological Exhibition, and the Victor Emanuel II. Monument. A committee formed by prominent members of Roman society is organising the reception of the members of the Congress to ensure their comfort and help them to see all they desire. In the Castel Sant' Angelo, where the Congress meets, there will be a post- and telegraph-office, and members can have their correspondence addressed by post to "Congresso Tuberculosi, Rome," or by telegraph to "Tuberculosis, Rome." At the bureau of the Congress the four official languages will be spoken. Numerous excursions to neighbouring places of interest are being organised, such as Tivoli, Subiaco, Ostia, Palestrina, Assisi, and Loretto. On arriving in Rome the members will find a bureau at the railway station to deal with lodgings. The hotels have been divided into five categories, the prices ranging from 15*s.* to 3*s.* 6*d.* daily. The Congress promises well, and to judge by the papers presented for reading in the three sections there should be some interesting discussions.

THE Church Missionary Society has lost within a few days of each other, from septicæmia, two members of its medical mission staff upon the North-West Frontier of India—Dr. Theodore Leighton Pennell, who received for his distinguished services the Kaisar-i-Hind gold medal in 1910, and Dr. William Henry Barnett.

Sir John William Moore, M.D. Dub., F.R.C.P. Irel., has been appointed one of the Honorary Physicians in Ordinary to His Majesty in Ireland, in the room of the late Sir Francis Richard Cruise.

TELEGRAPHISTS' CRAMP.

AN EXTRACT FROM THE REPORT OF THE DEPARTMENTAL COMMITTEE, GENERAL POST OFFICE, ON THE SUBJECT WITH ADDITIONAL MATTER [1]

BY H. THEODORE THOMPSON, M.D. CANTAB., F.R.C.P. LOND., F.R.C.S. ENG.,
ASSISTANT PHYSICIAN, LONDON HOSPITAL;
AND
J. SINCLAIR, M.D. DURH., M.R.C.P. LOND.,
SECOND MEDICAL OFFICER, GENERAL POST OFFICE.
(*The Medical Subcommittee.*)

PART I.

THE terms of reference to the Departmental Committee were: "To inquire into the prevalence and causes of the disease known as telegraphists' cramp, and to report what means may be adopted for its prevention."

Historical.

The earliest description of telegraphists' cramp as a specific disease was by M. Onimus [2] in Belgium in 1875. He gave a clear account of the symptoms and associated the complaint with the use of the Morse key. He says:—

> Cette affection ne serait pas très rare parmi les employés au télégraphe, surtout pour ceux qui se servent constamment du télégraphe Morse; ils la designent entre eux par l'expression de mal télégraphique.

M. Onimus recommended alternate duties upon the Hughes and Morse instruments as a preventive measure.

In August, 1882, Mr. Edmund Robinson,[3] surgeon to the Post Office at Leeds, read a paper before the British Medical Association upon four cases of telegraphists' cramp. The cases are clearly described, and it is noted that all were workers on the Morse instrument. Mr. Robinson points out the similarity of this complaint to the previously well-recognised cases of writers' cramp. In the same year (1882) a report was made on the subject of telegraphists' cramp by the chief medical officer of the General Post Office. Two years later Dr. Fulton,[4] who had been a telegraphist in the Edinburgh Post Office, described [5] the disease. Dr. Fulton appears to have had much experience of telegraphists' cramp, which, he stated, was probably more common than was generally supposed.

Isolated cases have been reported by observers in several countries, but in 1903 an extensive monograph on the "occupation neurosis of telegraphists" was published by Dr. E Cronbach.[6] He describes 17 cases which he had observed in Dr. Mendel's hospital in Berlin, and points out that only three of these were Morse workers, while 14 worked on the Hughes instrument. He shows clearly that there is a form of telegraphists' cramp due to continuous working on the Hughes instrument, and argues strongly that

[1] Permission for the publication of this article has been given by the Secretary, General Post Office.

substitution of the Hughes instrument for the Morse would have no effect in preventing the occurrence of cramp among telegraphists.

Definition of Telegraphists' Cramp.

Craft neurosis, occupation spasm, trade palsy, are the various names given to indicate a group of functional disorders which are characterised by a difficulty in the performance of the specific coördinated movements of certain occupations. The occupations in which the affection occurs are, for the most part, complicated acts brought to perfection by education and practice. The form of occupation spasm most commonly met with is writers' cramp, but many other forms exist.

Any instrument which calls for repeated fine muscular movements of the same kind may involve a relative "occupation spasm" or "craft neurosis." We have associated the term telegraphists' cramp with the disease which brings about a difficulty in making the specific coördinated movements needed for a proper manipulation of the particular instrument known as the Morse key, but the manipulation of the Baudot or Hughes keyboards[7] may similarly bring about their relative cramp (analogous to pianists' cramp); and all these three cramps are on parallel lines with writers' cramp. The various members of the group can be distinguished from one another by the fact that the pain and spasm occur only during use of the particular instrument on which the disabled worker has been employed; and disability in the use of one instrument does not necessarily imply disability in the use of any other instrument. A few exceptions to this general rule have been found in advanced or long-standing cases. (See Case 3, to be recorded later.)

In its medical aspect, before any cramp or spasm is apparent, there may be a stage characterised by subjective symptoms only, when the operator feels pain or discomfort in the operating hand or arm. The pain is referred to various parts of the limb, but it is constant in its time of appearance—that is, it occurs when the operator begins to key or soon afterwards, before any muscular fatigue is possible; and this is the only circumstance which enables this pain to be distinguished from pain caused by fatigue. The operator's electrical reactions are normal, and his muscular and nervous condition, so far as can be ascertained, is normal in all respects; and his work does not suffer. There is no visible cramp or spasm; visible cramp or spasm may or may not develop; and although this condition cannot therefore properly be called telegraphists' cramp, we are of opinion that it marks an early stage of the disease.

The characteristic feature of the disease—implied by the term "cramp" itself—is an "involuntary violent and painful contraction of the muscles"[8]; and throughout the telegraph service such visible spasm is regarded as the mark of the disease; and telegraphists' cramp may be defined as a disease of the central nervous system characterised by visible spasm of hand and (or) arm during the manipulation of a telegraph instrument, and by impairment of the power of making the specific coördinated movements needed for such manipulation.

Methods of Investigation.

1. An examination was made of certain well-marked cases of telegraphists' cramp who appeared before the committee for the purpose of demonstrating the disorder. In all, 17 cases were examined, all of whom had been reported as cases of telegraphists' cramp.

In the majority of cases the symptoms came on without any definite exciting cause; but in several cases the onset was attributed to excess of Morse sending work—e.g., on press wires or specially heavy circuits. The length of service in those cases considered by us to be true telegraphists' cramp was long—28, 25, 22, 19, 19, 15, 12, 10, 7, 6 years—an average of 16 years.

A very important point which was elicited by our inquiry was the ability of the subjects of Morse cramp to perform other actions besides Morse manipulation and to use other instruments than the Morse. This, we found, did not depend on the total length of service, for operators who had developed cramp after many years' service on the Morse were found to be able to use the Hughes instrument; but in those cases where pain and stiffness and spasm had occurred and the operators had continued work for long periods while suffering from cramp, movements of the hands other than those used in Morse sending became affected, and the Hughes instrument could not be used.

Difficulty only in Sending on Morse Instrument.

Period of operating ...	22 years	28 years	12 years	10 years
Period of cramp	2 ,,	1 year	1 year	1 year

Difficulty in Morse Sending, and Other Actions of the Hands Affected so that Other Instruments could not be Used.

Period of operating ...	19 years	25 years	19 years	15 years
Period of cramp	10 ,,	15 ,,	6 ,,	9 ,,

This shows that where the operator brought his case to notice early he could be usefully employed at the Hughes, but when, in spite of disability, he persisted in doing the work, the spasm extended to other actions beyond the special one of Morse sending.

A most careful examination was made of six of these cases. The nervous system was completely investigated and was found to be normal. No muscular wasting and no alteration in the electrical reactions were found. No alteration in sensibility of the skin of the hands or of the deeper structures was discovered. Such a result points to the disorder being of a central origin and not to any failure in the muscles or in the sensori-motor peripheral mechanism. A full account of six cases will be given in Part III.

2. By order of the committee, a circular with a set of questions to which answers were invited was sent to each of the 8153 telegraphists employed either in the Central Telegraph Office or on the telegraph side of all provincial offices which have a separate telegraph staff. Answers were received from 7317 telegraphists. 836 forms were not returned, or returned without reply.

148 telegraphists in one division of the Central Telegraph Office, a division which represented a mean between those divisions where Morse working is predominant and those where little Morse working is done—both those who complained of difficulty in manipulation as well as those who did not, in fact all who were available—were then personally examined by ourselves. Their physical well-being was inquired into, the state of their arm muscles was examined, and their method of manipulation at the key was watched. A sentence was keyed, printed in Morse signals on slip, and examined. We were assisted in this part of the examination by officers with expert knowledge.

93 telegraphists complained of some difficulty in keying. 13 of these were found to be affected with the malady. Of these 13 cases, 7 showed definite spasm in the right hand, but in the remaining 6 the disease was in the early or subjective stage. In these latter cases, however, the diagnosis was made after full consideration of the statements of the operators and their physical condition. The average length of service of these 13 operators at the Morse key when disability first appeared is 15·6 years. It is to be particularly noted that of these 13 officers no one of them was disabled from performing his allotted duty. Moreover, some of them, though conscious of difficulty, yet had not thought that they had cramp. In all these cases the cramp had affected the right hand only; 5 of them worked quite comfortably with the left and 5 used the left hand occasionally to relieve the right, but all were able to perform their work to the satisfaction of the supervising officers. In none of these cases were there any local abnormalities, the muscles were healthy and well developed, and there was no loss of power or sensation in the arm or hand.

The written replies showed that over one-third of the staff professed to feel more or less difficulty in manipulation, but it is necessary to emphasise the fact that in most cases the difficulty was slight, of a temporary character, and attributable to muscular fatigue alone.

The whole of the cases where the replies received and personal examination made indicated that the difficulty was apparently due to cramp (417 in all) were those of operators on the Morse key. In the cable room of the Central Telegraph Office replies were received from 105 telegraphists, and though some complaints of fatigue were made, we considered that in the cable room, where the Hughes and Baudot instruments are mainly used, true cramp was absent. Hughes and Baudot instruments are little used except in the cable room,

[7] Other telegraph instruments described on p. 69 of the report.
[8] Sir J. A. H. Murray's New English Dictionary.

whilst the Baudot instrument has only been introduced within the last few years.

The above result seems to show that in England the malady is chiefly associated with prolonged sending with the Morse key. This is no doubt due, in some measure, to the fact that the Morse key is the prevailing instrument. Partly, as will be shown, it is due to the fact that its use necessitates monotonous and unvarying movements. In Germany, where the use of the Hughes instrument is more prevalent, Cronbach has described several cases of cramp in workers on the Hughes instrument.

The following table shows the length of service in years when difficulty was first experienced at the Morse key. Of the 417 cases, only 243 answered the question dealing with this point; it is possible, had replies been received from all, that the incidence of the malady as regards service would have been different, but the available statistics show the following results:—

Years' service.	Male.	Female.	Years' service.	Male.	Female.
1- 5	22	20	16-20	51	5
6-10	39	23	21-25	23	1
11-15	42	8	26-30	5	—

It will be noticed that in the case of the female staff the malady is more apparent at an earlier period of service, and as the result of our investigations we find that the affection may seize upon the young telegraphist or on one who has had comparatively little manipulation to perform.

Ambidexterity.—Thirty-nine officers were ambidextrous before developing cramp, 259 acquired ambidexterity after developing cramp, 117 were not ambidextrous, and 2 did not reply.

Disability arising from the use of the pen.—In our examination of the 7317 replies we did not find any instance of writers' cramp, though we noticed several cases of fatigue and consequent interference with easy penmanship.

(To be continued.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

County Borough of West Bromwich.—Mr. R. Woolsey Stocks's report for 1911 calls attention to the problem of "dull children," who approach 10 per cent. of the children examined and who are at least two standards below the average. Mr. Stocks is convinced that the large proportion of these children could be taught industrial subjects with comparative ease, especially as the teaching necessitates a much more individual method of instruction than is obtainable in the ordinary class work. In contradistinction to the decrease noticed in many districts the number of children harbouring body lice was found to be distinctly above that of previous years. The report also calls attention to a very serious defect—the all too frequent absence of any form of underclothing in girls. The medical officer attends on Saturday mornings at the education office to receive reports from the attendance officers and to examine any children specially reported to him by the committee. During the year 148 cases were examined; of these, 15 children were found to be able to attend school, and an order was made to this effect. As no special facilities for the teaching of mentally deficient children exist, only four of the seven discovered were excluded. The report calls attention to the need for provision of a dental clinic in view of the large number of cases needing treatment and the lack of means for this treatment. Only two cases of ringworm were noted out of a total of over 1000 children examined.

Counties of Fife and Kinross.—The very full statistics given in Dr. J. R. Currie's report for 1910–11 make it specially interesting. Among the children examined there were 253 cases of otorrhœa and 382 of abnormalities of the heart and circulation, but only 27 examples of phthisis, this representing a percentage incidence of 0·1 on the total children examined. It is suggested that the disease may be somewhat more prevalent among children than the literal interpretation would indicate, not because cases are missed in the course of inspection, but because phthisical children rapidly become too ill to appear in school at all. Despite these facts, however, it is undoubtedly true that the percentage incidence of phthisis among school children is much lower than is often imagined. Of tuberculosis other than phthisis, 50 cases were noted, 31 being gland cases, 6 examples of hip disease, 2 of spinal caries, and 5 of other tuberculosis. In this connexion the value of medical inspection comes out strikingly in the following extract from Dr. A. F. McBean's report on the Fourth Inspectoral Area:—

> One case was examined last year on request of the parent. She had been noticed to limp slightly. I made full examination and measurements, the mother, who was present, wishing it. I made diagnosis of hip-joint disease and advised the mother to get their own doctor to attend to the case. This was done and the child put under treatment. I saw her at another school this year, after 14 months, and was glad to see her looking very much stronger and without trace of a limp. Her mother stated the girl was in excellent health now.

One case of tongue-tie is recorded, and in view of the opinion of some authorities who regard this condition as mythical it would be interesting to have details which are not given. Pigeon-chest was found in 18 children, curvature of the spine in 8, and web-fingers in 2; there were only 13 cases of ringworm, but 237 of anæmia. Of the children examined, 75·3 per cent. were well nourished, 23·3 per cent. ill-nourished, and 1·4 per cent. emaciated. The percentage relations for boys and girls were found to be almost identical. The total percentage for defective nutrition was given as 24·7 per cent. The causes of malnutrition are held to be injudicious rather than inadequate feeding, depending largely on the obsolescence of the art of cookery. Very encouraging results are recorded with regard to the improvement in the cleanliness of children's heads, one example in the heart of the mining district being recorded where there was not a single verminous head among 400 children. It would undoubtedly be easier for the spread of these vermin to be guarded against if the cloak-room accommodation in schools were more ample, so that the children's clothing, and particularly hats and caps, could be kept separately. The treatment provided after medical inspection does not appear to have been very satisfactory, and intimations calling on parents to deal with carious teeth were only sent out in special circumstances, because it was recognised that proper dental treatment was in most cases unattainable. Only a little more than half the children found defective appear to have obtained any kind of treatment. The impediments to treatment are considered at more length under the headings of indifference, ignorance, and cost. It is unfortunate, however, that statistics are not given with regard to the number of cases to which these different factors apply. Some interesting figures are given with regard to employment after school-age, and it is pointed out that it is particularly necessary for children who are destined for factory work that they should be medically inspected and their defects pointed out to their parents. Of 6500 certificates issued by certifying factory surgeons in 1910 to which qualifying conditions were attached, 1160 related to defective vision, 884 to nits and vermin, and 805 to carious teeth, some sufferers being forbidden to work in company with other persons, the majority being excluded entirely unless their defects were cured. The above categories are particularly those which figure conspicuously in school medical officers' returns and relate to ailments which can be remedied during school life. On the question of the cause of failure in the treatment of eye and teeth defects, it is said that the fee of the expert is too large to be paid by the parents of children attending elementary schools, and the report urges strongly the establishment of school clinics at which children might receive treatment for such conditions as do not come within the scope of ordinary medical practice. But in Scotland at the present time no power exists to establish school clinics, the field being therefore open for private enterprise or for legislation. The number of parents present at examinations seems to have been rather low: in one inspectoral area only 13 per cent. of the parents attended; in others 11 per cent. and 6·5 per cent. It is noted that many children were overburdened with clothing.

School Board of Glasgow.—Dr. Ernest T. Roberts's report is the first annual report and covers the year ending June 30th, 1910. The staff consists of 1 full-time officer, 1 half-time officer, and 20 quarter-time medical officers. There are in addition 7 school nurses. The school service is thus very similar to that in existence in London. During

the year 9511 notifications of defects were made to parents, and where a re-examination was made it was found that 23·7 per cent. were cured and 30·2 per cent. improved, the remainder being still under observation. An examination clinic has been established since October, 1909, where special cases are dealt with on Saturday mornings and other times when necessary. The work has greatly increased, and at the present time Tuesday afternoon and Thursday and Saturday mornings are set apart for this purpose. Children who are unable to attend at the office are also visited at their own homes and others seen at the schools. Mentally deficient children who are badly nourished or the subjects of rickets have been given emulsion of cod-liver oil with hypophosphites, and the medical officer suggests that this may tend to expedite the return to the schools of the children whose defect is not permanent. Three schools are now fitted with shower baths, and the medical officer urges that as soon as possible these should be installed in all schools situated in the poorer parts of the city. Baths were at the date of the report in process of installation in two other schools. A very interesting table is given showing the percentage of children from 1 to 5 years attacked by and surviving measles, whooping-cough, chicken-pox, and diphtheria. There is a useful section of the report on the medical inspection of deficient children by Dr. Robert Bruce. There are in Glasgow 11 centres with special facilities for receiving, feeding, and educating these children, which are placed throughout the city so as to meet the requirements of the populous districts. The dietary table of dinners is given, and might well form the basis for school menus for necessitous children who are not physically defective. Cod-liver oil and hypophosphites, already mentioned, are given after the dinner. Mr. John Carswell reports on the mentally deficient children of whom there were 825 in 1910. The method in vogue in Glasgow is to group these cases in special probationary classes for one year before they are definitely classed as mentally deficient. The marked preponderance of male children over female has been noted, but this does not appear in the case of Roman Catholics; no explanation of this fact is given. It is pointed out that the mental defects which render the children incapable of receiving proper benefit from instruction in the elementary schools may be limited to letter or word blindness, or to delayed development of the speech centre in the brain, or to a condition of mental bewilderment caused by bad physical conditions, none of which need entail permanent deficiency. Mr. Carswell states that his experience leads him to believe that there are two distinct periods when mental deficiency shows itself—first, between the ages of 5 and 7; and second, when the third or fourth standard is reached. It is from among boys and girls who have got on tolerably well up to the third or fourth standard, but who get no further, that criminal youths and other troublesome persons are largely recruited. The mentally deficient adult, whose mentally defective powers show in early school life, is usually a docile and easily managed person, but the boy whose mental incapacity does not emerge till the affective life becomes active enters upon adult life with a poor equipment of education and uncontrolled impulse and readily becomes the prey to the temptations of the street. It is suggested that children who cease to make progress after reaching the third or fourth standard, even though the failure may be attributed to some cause, such as absence by truancy or otherwise, should be admitted for special examination. Glasgow is fortunate in having special classes for the semi-deaf and the semi-mute, and it is suggested that good use might be made of the years between two and six in teaching children to speak either by admission to special schools for very young deaf children or by visits of an articulation teacher to the homes once a week or once a fortnight to explain to the mother the needs of the child and to give half an hour's lesson in the presence of the mother. The report for 1911 has now been issued.

County of Berkshire.—The report of the school medical officer for 1911 presents statistics of inspections extending over three years and dealing with between 17,000 and 18,000 children. It was found that in the country districts where the schools are very small the strict adherence to the requirements of the Board of Education necessitated considerable waste of the medical officer's time, for if the children who came within the age groups only were examined, there were not enough to occupy the time, while the schools were too far apart for more than one to be done in a day. The detail of inspections has therefore varied in accordance with whether the school population was over or under 75. The parents of 75·1 per cent. of children inspected in 1911 attended the examinations, as compared with 77·5 in the two previous years and 78·9 in 1908. The figures for cleanliness are practically the same as those of the previous years, but there has been a progressive improvement since medical inspection, as may be noted by the proportion in 1908. In this latter year 22 per cent. had pediculi or nits in the hair; in 1909, 16·5 per cent; in 1910, 14·26 per cent.; and in 1911, 13·16 per cent. In 1908 over 9 per cent. are noted as having defective nutrition; 7·2 per cent. in 1909; 7·4 per cent. in 1910; and 3·62 per cent. in 1911. It would be interesting to know to what this sudden drop is attributed, as no indication is given in the report, and it does not appear probable that the change can be the result of the medical inspection. It suggests the employment of a new standard or a new medical officer. In a special report by Dr. C. L. Lakin the children from the poorer homes are contrasted with children of the better homes, and it is shown that in the poorer children entrance to school is associated with quickening in growth, whereas in the case of better-off children entrance to school life is associated with a slight retardation of growth. A table of indices of nutrition is given which is computed by expressing the relation of stature to weight by the number of grammes corresponding to each centimetre of stature. Children in the poorer schools weigh 170 grammes per centimetre of stature, children in the better schools weigh 187 grammes. On reviewing the points mentioned Dr. Lakin concludes that if the home circumstances could be improved the physique of the elementary school children would be coincidently raised.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 94 largest English towns having an estimated population of 17,559,219 persons in the middle of this year, 8593 births and 4756 deaths were registered during the week ending March 23rd. The annual rate of mortality in these towns, which had been 15·4, 14·4, and 14·6 per 1000 in the three preceding weeks, declined to 14·1 per 1000 in the week under notice. During the first 12 weeks of the current quarter the mean annual death-rate in these large towns averaged 16·3 per 1000, while in London during the same period the average annual death-rate did not exceed 15·4 per 1000. The annual death-rates last week in the several towns ranged from 4·9 in Walthamstow, 5·7 in Croydon, 5·8 in Gillingham, 6·9 in Ilford, and 7·2 in Ealing, to 20·3 in Great Yarmouth, 22·6 in Salford, 23·3 in Dewsbury, 24·2 in Warrington, and 24·6 in Wolverhampton.

The 4756 deaths from all causes were 174 fewer than the number in the previous week, and included 425 which were referred to the principal epidemic diseases, against 378 and 434 in the two preceding weeks. These 425 deaths from the principal epidemic diseases included 155 from whooping-cough, 138 from measles, 69 from infantile diarrhœal diseases, 35 from diphtheria, 17 from scarlet fever, and 11 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3 per 1000, against 1·1 and 1·3 in the two preceding weeks. The deaths attributed to whooping-cough, which had been 142, 136, and 159 in the three preceding weeks, slightly fell to 155 last week, and caused the highest annual death-rates of 1·6 in Barrow-in-Furness, 1·8 in Great Yarmouth and in Bury, 2·0 in Salford, 2·5 in Merthyr Tydfil, and 3·3 in Rhondda. The deaths referred to measles, which had been 109, 101, and 137 in the three preceding weeks, were 138 last week; the highest annual death-rates from this disease were 1·8 in Oldham, 2·0 in Cardiff, 2·4 in Portsmouth, 3·8 in Salford, and 5·7 in Warrington. The fatal cases of diarrhœa among infants under 2 years of age, which had steadily increased from 39 to 56 in the four preceding weeks, further rose to 69 last week, and included 21 in London and its suburban districts, 8 in Liverpool, 4 in Manchester, 4 in Sheffield, and 4 in Rhondda. The deaths attributed to diphtheria, which had been 53, 49, and 55 in the three preceding weeks, declined to 35 last week; 10 deaths were recorded in London, 3 in Portsmouth, 2 in Sheffield, and 2 in Rhondda. The deaths referred to

scarlet fever, which had been 21, 25, and 13 in the three previous weeks, were 17 last week, of which 4 were registered in Birmingham, 3 in Sheffield, and 2 in Nottingham. The fatal cases of enteric fever, which had been 14 in each of the two preceding weeks, declined to 11 last week, and included 2 in Warrington, 2 in Sheffield, and 2 in Cardiff.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had been 1392, 1357, and 1384 at the end of the three preceding weeks, had declined to 1368 on Saturday last; 137 new cases of this disease were admitted to these hospitals during the week, against 160, 161, and 152 in the three preceding weeks. These hospitals also contained on Saturday last 1073 cases of diphtheria, 542 of whooping-cough, 210 of measles, and 59 of enteric fever, but not one of small-pox. The 1168 deaths from all causes recorded in London were 63 in excess of the number in the previous week, and were equal to an annual death-rate of 13·5 per 1000. The deaths referred to diseases of the respiratory system, which had steadily declined from 545 to 224 during the six preceding weeks, rose to 246 last week, but were 49 below the number recorded in the corresponding week of last year.

Of the 4756 deaths from all causes in the 94 large towns, 164 resulted from different forms of violence, and 368 were the subject of coroners' inquests. The causes of 33, or 0 7 per cent., of the deaths registered last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, Nottingham, and in no fewer than 71 other smaller towns. The 33 uncertified causes of death last week included 8 in Birmingham, 7 in Liverpool, 5 in Gateshead, and 3 in Sunderland.

HEALTH OF SCOTCH TOWNS.

In the 18 largest Scotch towns, having an estimated population of 2,182,400 persons in the middle of this year, 1232 births and 726 deaths were registered during the week ending March 23rd. The annual rate of mortality in these towns, which had declined from 18·7 to 15·4 per 1000 in the three preceding weeks, rose to 17·4 per 1000 in the week under notice. During the first 12 weeks of the current quarter the mean annual rate of mortality in these towns averaged 18 5 per 1000, and was 2·2 per 1000 above the mean rate recorded during the same period in the 94 large English towns. The annual death-rates in the several Scotch towns last week ranged from 5·3 in Partick, 10 3 in Kirkcaldy, and 11·3 in Motherwell, to 20·5 in Dundee, 24 0 in Greenock, and 25·5 in Kilmarnock.

The 726 deaths from all causes were 83 in excess of the number in the previous week, and included 95 which were referred to the principal epidemic diseases, against 76 and 80 in the two preceding weeks. Of these 95 deaths, 50 resulted from measles, 16 from infantile diarrhœal diseases, 13 from whooping-cough, 9 from diphtheria, 5 from scarlet fever, and 2 from enteric fever, but not one from small-pox. These 95 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·3 per 1000, or 1·0 per 1000 above that recorded in the 94 large English towns. The deaths attributed to measles, which had been 56, 39, and 47 in the three preceding weeks, rose to 50 last week, and included 22 in Glasgow, 9 in Edinburgh, 4 in Greenock, 3 in Leith, and 3 in Kilmarnock. The deaths of infants under 2 years of age referred to diarrhœal diseases, which had been 8 in each of the two preceding weeks, rose to 16 last week; 4 deaths were registered in Glasgow and 4 in Dundee. The fatal cases of whooping-cough, which had steadily declined from 18 to 6 in the four preceding weeks, rose to 13 last week, of which 6 occurred in Glasgow and 3 in Dundee. The deaths attributed to diphtheria, which had declined from 22 to 8 in the four preceding weeks, were 9 last week, and included 4 in Glasgow. The deaths referred to scarlet fever, which had been 10 and 7 in the two previous weeks, further declined to 5 last week, of which number 3 were registered in Greenock. The 2 fatal cases of enteric fever occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had continuously declined from 220 to 98 in the six preceding weeks, rose to 107 last week, and 18 deaths were attributed to different forms of violence.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,157,014 persons in the middle of this year, 633 births and 549 deaths were registered during the week ending March 16th. The annual rate of mortality in these towns, which had been 22·1 and 23 1 per 1000 in the two preceding weeks, further rose to 24·7 per 1000 in the week under notice. During the first eleven weeks of the current quarter the mean annual death-rate in these Irish towns averaged 23 6 per 1000; in the 94 large English towns the mean annual death-rate during the same period did not exceed 16 5 per 1000, while in the 18 Scotch towns it was equal to 18·6 per 1000. The annual death-rates in the several Irish towns during the week were equal to 31 8 in Dublin (against 12 7 in London), 19 6 in Belfast, 27·9 in Cork, 20·4 in Londonderry, 14·9 in Limerick, and 20·9 in Waterford; in the remaining 16 of these Irish towns the mean annual death-rate amounted to 22·2 per 1000.

The 549 deaths from all causes in the 22 Irish towns were 37 in excess of the number in the previous week, and included 40 which were referred to the principal epidemic diseases, against numbers increasing from 27 to 41 in the three preceding weeks; of these 40 deaths, 16 resulted from whooping-cough, 8 from infantile diarrhœal diseases, 7 from measles, 5 from diphtheria, 3 from enteric fever, and 1 from scarlet fever, but not one from small-pox. These 40 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000; the death-rate from these diseases in the same week did not exceed 1·3 per 1000 in the 94 large English towns, while in the 18 Scotch towns it was equal to 1 9. The deaths attributed to whooping-cough, which had been 14, 16, and 13 in the three preceding weeks, numbered 16 in the week under notice, and included 10 in Dublin and 4 in Belfast. The deaths of infants under two years of age from diarrhœal diseases, which had increased from 5 to 13 in the three preceding weeks, declined to 8, and comprised 4 in Dublin, 3 in Belfast, and 1 in Londonderry. The 7 fatal cases of measles were 3 in excess of the average in the three preceding weeks, and were all registered in Dublin; the 5 deaths from diphtheria and the 3 fatal cases of enteric fever were also recorded in Dublin, and that of scarlet fever in Belfast.

The deaths referred to diseases of the respiratory system, which had declined from 239 to 135 in the five preceding weeks, rose to 148 in the week under notice. Of the 549 deaths from all causes in the 22 Irish towns, 151, or 28 per cent., occurred in public institutions, and 9 resulted from different forms of violence. The causes of 21, or 3 8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 94 large English towns the proportion of uncertified causes of death did not exceed 0·8 per cent.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1912.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 5·3 per 1000 of the population, estimated at 4,519,754 persons in the middle of the year. In the three preceding months the rates were 7·8, 6·3, and 5·3 per 1000 respectively. The lowest rates last month were recorded in the City of Westminster, Stoke Newington, Islington, Holborn, and the City of London; and the highest rates in Bermondsey, Deptford, Greenwich, Lewisham, and Woolwich. The prevalence of scarlet fever showed but little variation from that recorded in the preceding month; this disease was proportionally most prevalent in Fulham, St. Marylebone, Battersea, Deptford, Greenwich, Lewisham, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals,

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.

which had been 2103, 1878, and 1473 at the end of the three preceding months, had further declined to 1375 at the end of last month; the weekly admissions averaged 166, against 198 and 165 in the two preceding months. Diphtheria was slightly more prevalent than it had been in the preceding month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Paddington, Hampstead, Finsbury, Bermondsey, Greenwich, and Lewisham. The Metropolitan Asylums Hospitals contained 1129 diphtheria patients at the end of last month, against 1327, 1294, and 1191 at the end of the three preceding months; the weekly admissions averaged 137, against 168, 180, and 134 in the three preceding months. The prevalence of enteric fever also showed a slight increase last month; this disease was proportionally most prevalent in Hampstead, Bethnal Green, Stepney, Southwark, Bermondsey, Lambeth, and Wandsworth. There were 64 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 85, 76, and 49 at the end of the three preceding months; the weekly admissions averaged 10, against 9 and 8 in the two preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Hackney, Finsbury, Shoreditch, Bethnal Green, Bermondsey, Deptford, and Greenwich. The 43 cases of puerperal fever notified during the month included 7 in Hackney, 6 in the City of Westminster, 4 in Wandsworth, and 3 each in Paddington, St. Pancras, Southwark, and Lambeth The 12 cases of cerebro-spinal meningitis included 3 in Stepney; and the 3 cases of poliomyelitis belonged respectively to Hackney, Wandsworth, and Greenwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the four weeks ending March 2nd the deaths of 5889 London residents were registered, equal to an annual rate of 17·9 per 1000 of the population; in the three preceding months the rates had been 14·1, 16·1, and 16·3 per 1000. The death-rates last month ranged from 13·9 in Lewisham, 14·8 in Wandsworth, 15·1 in Hackney, 15·2 in Battersea, 15·3 in the City of London, and 15·6 in Greenwich, to 20·1 in Shoreditch, 22·0 in Southwark, 22·5 in Bermondsey, 24·3 in Finsbury, and 25·1 in Holborn. The 5889 deaths from all causes included 268 which were referred to the principal infectious diseases; of these, 60 resulted from measles, 6 from scarlet fever, 37 from diphtheria, 98 from whooping-cough, 9 from enteric fever, and 58 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Hammersmith, Chelsea, the City of Westminster, Stoke Newington, Holborn, and Lewisham, and the highest rates in Fulham, Finsbury, Shoreditch, Stepney, Poplar, Southwark, and Bermondsey. The 60 deaths from measles showed a decline of 160 from the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in Southwark, Lambeth, Camberwell, and Greenwich. The 6 fatal cases of scarlet fever were 23 fewer than the corrected average number, and belonged respectively to St. Marylebone, St. Pancras, Hackney, Finsbury, Battersea, and Wandsworth. The 37 deaths from diphtheria were 22 below the corrected average number, and included 4 in Shoreditch and 3 each in St. Pancras, Bethnal Green, Stepney, and Southwark. The 98 fatal cases of whooping-cough showed a decline of 61 from the corrected average number; this disease was proportionally most fatal in Stepney, Poplar, Southwark, Bermondsey, and Woolwich. The 9 deaths from enteric fever were 1 less than the corrected average number; of these 9 deaths, 2 belonged to Fulham, 2 to Bermondsey, and 2 to Lambeth. The mortality from diarrhœa and enteritis among children under two years of age was proportionally greatest in Finsbury, Shoreditch, Stepney, and Battersea. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases (excluding diarrhœa) was 53 9 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: E. C. Cridland, to the *Irresistible*, on recommissioning, and to the *Monarch*, on commissioning; and H. H. Gill, to the *Irresistible*, on the *Monarch* commissioning. Staff-Surgeons: J. C. Bringan, to the *Monarch*, on commissioning, and to the *Gossamer*, lent; A. J. Wernet, to Queensferry Sick Quarters; P. L. Crosbie, to the *Vivid*, additional, for disposal; C. R. Sheward, to the *Yarmouth*, on commissioning; S. Roach, to the *Devonshire*, temporary; G. Gibson, to the *Bellona*, on recommissioning; and G. E. McLeod, to the *Sentinel*, on recommissioning. Surgeon: T. Creaser, to the *Pembroke*, additional.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors (dated March 21st, 1912): John P. J. Murphy, Arthur R. Greenwood, and William L. Bennett.

Lieutenant-Colonel J. Donaldson has embarked for a tour of service in South Africa. Lieutenant-Colonel W. A. Morris has arrived home from India. Lieutenant-Colonel H. C. Thurston, C.M.G., has taken up duty at the Royal Military College, Sandhurst, as surgeon, in succession to Lieutenant-Colonel C. C. Reilly. Lieutenant-Colonel A. P. Blenkinsop has embarked for a tour of service in India. Lieutenant-Colonel E. H. L. Lynden Bell has been granted general leave of absence home from India for eight months. Lieutenant-Colonel G. G. Adams has been selected to command the Station Hospital at Secunderabad, in succession to Lieutenant-Colonel H. S. McGill, tour-expired.

Major H. E. Winter has been appointed Deputy Surgeon to the Royal Hospital at Chelsea, in succession to Major F. Kiddle. Major R. W. Clements has taken over medical charge of the Enteric Fever Convalescent Depôt at Wellington. Major W. B. Fry has rejoined from the Egyptian Army. Major L. P. More has taken up duty at the Station Hospital at Secunderabad. Major P. H. Collingwood has been transferred from Plymouth to the Military Hospital at Devonport. Major J. J. W. Prescott, D.S.O., has taken up duty in the Southern Command. Major P. C. Douglass has embarked for a tour of service in India. Major F. G. Richards has arrived home on duty from Jamaica, tour-expired. Major E. B. Steel has been transferred from Delhi to the Station Hospital at Muttra. Captain E. P. Connolly, on arrival in India, has been appointed to the Station Hospital at Lahore. Major F. W. Begbie has rejoined at Colchester from Ipswich on relief by Lieutenant-Colonel J. Battersby. Major N. Faichnie, specialist sanitary officer to the Fifth (Mhow) Division, has been granted eight months' general leave of absence.

Captain E. G. Anthonisz and Captain A. E. F. Hastings have been detailed for duty on board the transport s.s. *Plassy*, which left Bombay for Southampton on March 13th. Captain F. A. Stephens has been appointed for duty to the Station Hospital at Rawal Pindi. Captain D. M. Corbett has been granted eight months' general leave of absence home from India. Captain J. A. W. Webster has been transferred from Kilkenny to the Military Hospital at Cork for duty. Captain T. J. Potter has left the London District for duty in Egypt. Captain J. A. B. Sim has arrived home from Bermuda on the expiration of his tour of foreign service. Captain F. C. Sampson has been appointed to the Scottish Command. Captain C. E. W. S. Fawcett has taken up duty in the Dublin District. Captain C. E. Fleming has been selected for appointment as Specialist in Ophthalmology to the South African Command.

Lieutenant W. H. O'Riordan has embarked for a tour of service in India. Lieutenant C. D. K. Seaver, from Fermoy, has been posted for duty at Ballincollig. Lieutenant M. J. Williamson, from Tidworth, and Lieutenant C. L. Franklin, from Preston, have embarked for a tour of service in South Africa. Lieutenant R. C. G. M. Kinkead has been transferred from Queenstown to the Military Hospital at Cork. Lieutenant T. W. Stallybrass has left the Royal Victoria Hospital, Netley, for service in Egypt. The following Lieutenants on probation have joined the Royal Army Medical College for the junior course of instruction: B. Biggar, T. A. Weston, D. T. M. Large, W. F. Christie, R. K. Mallam,

W. B. Stevenson, C. J. Blaikie, J. H. M. Frobisher, C. M. Ingoldby, O. W. J. Wynne, D. T. Richardson, E. A. Strachan, W. McNaughtan, S. J. Higgins, A. Hood, J. L. Richie, H. R. L'Estrange, P. A. With, and S. J. Barry.

INDIAN MEDICAL SERVICE.

The King has approved of the promotion of the following officers:—

Majors to be Lieutenant-Colonels (dated Jan. 30th, 1912): Bruce Gordon Seton, V.H.S., Robert Henry Elliot, and Robert King Mitter.

Captains to be Majors: George Browse, Herbert Armstrong Williams, D.S.O., and William Christopher Long (dated Jan. 27th, 1912); James Drummond Graham, Cuthbert Allan Sprawson, Maxwell MacKelvie, William Henry Cazaly, Walter Valentine Coppinger, William Mitchell Houston, William David Acheson Keys, Alexander Chalmers, and Samuel Robert Godkin (dated Jan. 28th, 1912).

Lieutenants to be Captains (dated Jan. 30th, 1912): Andrew Monro Jukes, Gwilym Gregory James, William David Keyworth, John Howard Horne, and Alfred John Lee.

Lieutenant-Colonel C. J. Sarkies has arrived home on leave of absence from India. Lieutenant-Colonel F. C. Pereira has been selected for appointment as District Medical Officer at Salem. Lieutenant-Colonel K. Prasad has passed the prescribed test in the Shan language by the lower standard.

Major H. Ainsworth has been granted furlough for three months. Major H. A. Smith has been selected as Civil Surgeon of Simla East in succession to Lieutenant-Colonel H. B. Melville. Major E. A. C. Matthews has been appointed to officiate as Superintendent of the X Ray Institute at Dehra Dun during the absence on leave of Major E. A. Walter. Major C. M. Mathew has been appointed to officiate as Medical Storekeeper in Madras Presidency. Major H. J. K. Bamfield has been appointed Specialist in Midwifery and Diseases of Women and Children in the Second (Rawal Pindi) Division.

Captain J. H. Horne has been placed on special duty for the investigation of malarial fevers in Madras Presidency for a period of three years. The services of Captain F. P. Mackie, officiating chemical examiner, Government analyst and bacteriologist for the United Provinces and Central Provinces, have been replaced at the disposal of the Home Department. Captain R. Knowles has been appointed to hold civil medical change of the Shansi District, in addition to his military duties, in succession to Major C. Milne, transferred. Captain J. E. Clement has assumed charge of Montgomery as Civil Surgeon. The services of Captain A. W. Howlett have been placed temporarily at the disposal of the Government of India. Captain D. Munro has been granted an extension of leave for three months. Captain W. C. Gray has been appointed Professor of Biology and Secretary to the Principal in the Medical College, Madras. Captain H. B. Scott has been appointed to officiate as Civil Surgeon at Swebo.

TERRITORIAL FORCE.

Royal Army Medical Corps.

4th London General Hospital, Royal Army Medical Corps: James Purves Stewart, late Surgeon-Lieutenant, East London (Tower Hamlets) Royal Engineers (Volunteers), to be Captain (dated Feb. 29th, 1912).

Notts and Derby Mounted Brigade Field Ambulance, Royal Army Medical Corps: Lieutenant Arthur B. Dunne to be Captain (dated Feb. 17th, 1912).

2nd Highland Field Ambulance, Royal Army Medical Corps: Major Alexander Ogston to be Lieutenant-Colonel (dated Feb. 12th, 1912).

2nd Home Counties Field Ambulance, Royal Army Corps: Lieutenant William H. Flint to be Captain (dated Dec. 8th, 1911).

1st Lowland Field Ambulance, Royal Army Medical Corps: Lieutenant Geoffrey Balmanno Fleming, from the List of Officers attached to Units other than Medical Units, to be Lieutenant (dated Feb. 21st, 1912).

1st West Riding Field Ambulance, Royal Army Medical Corps: Lieutenant Walter Lister to be Captain (dated Feb. 21st, 1912).

1st London (City of London) General Hospital, Royal Army Medical Corps: The undermentioned officers resign their commissions (dated March 27th, 1912):— Lieutenant-Colonel Norman Moore, and Lieutenant-Colonel William H. Cripps.

Attached to Units other than Medical Units.—Lieutenant Henry A. C. Harris to be Captain (dated Dec. 8th, 1911).

ESPERANTO AND THE RED CROSS.

Dr. G. Jameson Johnston, consul in Ireland for the All-World Esperanto Doctors' Association (to literally translate Tutmonda Esperanta Kuracista Asocio), writes, with reference to the note on this subject in our issue of March 9th: "Permit me to state that I was present at the Red Cross manœuvres which took place at the Seventh International Esperanto Congress in Antwerp last August. The municipal authorities granted the use of one of the public squares, and the military the necessary equipment. The nurses, bearers, &c., were members of the local Red Cross societies, and the patients were selected at random from the representatives of the 36 different nations who attended the congress. There were a first-dressing station, receiving station, and base hospital. A diagnosis card was attached to each patient, and international committees of doctors (my colleagues were a Russian and a Chilian) reported on the treatment. The arrangements were perfectly carried out, no language being used save Esperanto. Although many 'isms' are represented in the movement, still the 'cranks' form a very small part of the whole body. The language is now long past the 'hobby' stage and is a world wide living language, remarkably easy to learn. Here in Dublin there are over 15 members of the Universal Medical Association, and more are joining. The Provost of Trinity College, who graduated in medicine, is a strong supporter of Esperanto." We accept our correspondent's statement that the cranks form a very small part of the whole body of Esperantists, but this does not vitiate our argument that the progress of Esperanto in this country has been retarded by its association in the public mind, rightly or wrongly, with other ideas outside that of an international means of communication between the peoples of the world.

ROYAL ARMY MEDICAL CORPS SHORTAGE.

Owing to deficiencies from failure to obtain recruits, approval has been given to call up with their own consent, for duty with regular companies, trained special reservists of category (*a*) of the Royal Army Medical Corps Special Reserve. Recruiting has recently been opened throughout Ireland for the Royal Army Medical Corps Reserve.

LITERARY INTELLIGENCE.—We are informed that the Liverpool School of Tropical Medicine will shortly issue in at least four parts every year, the "Annals of Tropical Sanitation," edited by Professor Sir Ronald Ross, K.C.B., with the assistance of Colonel W. G. King, C.I.E., and Professor W. J. Simpson, C M.G. The annual volume will contain at least 500 pages, and the size of the page will be the same as that of the "Annals of Tropical Medicine and Parasitology." Annual subscription one guinea, payable in advance. Separate numbers 7*s.* 6*d.* each.

THE RELATIONS OF THE CLERGY AND THE MEDICAL PROFESSION.—The special committee which was appointed at a conference of the clerical and medical professions in London in October, 1910, "to consider the asserted results and the rapid development of so-called 'Spiritual' or 'Faith Healing' movements," has issued a report. The committee held 22 meetings and took evidence from many medical practitioners, clergy, and persons associated with "Spiritual" or "Faith Healing." The committee finds "that after careful and extensive inquiry there is not sufficient proof of any general or frequent failure (as has been alleged) of cordial relations between the medical practitioner and the minister of religion in their respective ministrations to the same sick person. Such cases are exceptional and rare." Any separate or independent treatment of the sick on the part of the clergy is strongly deprecated. There is further room for coöperation, within well-defined limits, between the two professions, particularly in certain nervous and mental cases—functional disorders, minor obsessions, or vicious habits, in which patients can often be approached from the spiritual side when medical suggestion is difficult to apply. An enlarged permanent committee of clergy and medical practitioners has been constituted to continue investigations, with the Right Rev. Herbert E. Ryle, D.D., Dean of Westminster, as chairman.

Correspondence.

"Audi alteram partem."

THE VALUE OF PNEUMOCOCCUS VACCINE IN THE TREATMENT OF PNEUMONIA.

To the Editor of THE LANCET.

SIR,—I do not propose to take up your space with any discussion of the intimate pathology of pneumonia, which would yet be in point in relation to the influence of vaccines upon the disease. I trust that before Dr. Nathan Raw finally advises the use of such frequent doses of the vaccine in pneumonia he will support his recommendation by a considerable series of cases besides the two very interesting ones to which he alludes. One's small experience of the effect of vaccines, when they have any useful effect, is that they are followed by some reaction symptoms, and one would doubt the advantage, or even the safety, of giving a second dose at or before the reaction period of the first. Perhaps I have too vividly in my recollection a drama, *The Doctor's Dilemma*, to which I listened with amusement but some heart searchings a year or two ago!

The control of diphtheria by antitoxin is, of course, a totally different treatment from that now in question, being the use of a serum, not a vaccine.

I am, Sir, yours faithfully,

Portland-place, W., March 23rd, 1912. R. DOUGLAS POWELL.

A NATIONAL HEALTH WEEK.

To the Editor of THE LANCET.

SIR,—Will you grant me a few lines of your space to call the attention of those specially interested in public health to the work which is now being done in connexion with a National Health Week.

The main point underlying the idea is that the time has nearly approached when if there is to be any further marked advance in the hygienic condition of the people the public conscience must be stirred as to the importance of personal hygiene—e.g., cleanliness, rational feeding, and matters of this kind. There is not the slightest suggestion that in instituting Health Week any criticism is to be made of the work done by the recognised sanitary authorities, the whole idea being that what is done will be supplementary to their work.

For Health Week to be a success it is necessary for all who are interested in matters hygienic to give any aid they can to the project, and it is obvious that in those towns and districts where a Health Week is being observed great help will be rendered to the movement if the medical profession generally give a strong support to it. The main idea, therefore, of the celebration is to try to arouse an interest in the private individual in matters concerning his own and his family's health; to lead him to understand what infant mortality means and how it can be dealt with; to let him see how necessary it is for private effort to be added to public in order that the great scourge of consumption may be properly dealt with. This and many other problems now awaiting solution can only be effectively dealt with by the whole-hearted coöperation of the private citizen.

I desire particularly to emphasise the view that we are not forming any new society. We are not clashing with any existing institute or authority. The committee is, in fact, mainly composed of officers of the leading health societies, nominated by those societies as their representatives. Any local Health Week celebrations will be under the control of a local committee, in which it is hoped that all sorts and conditions of people will join. The first Health Week will begin on Sunday, April 28th. The extent to which it is observed will depend entirely on local conditions. It is hoped that the clergy will lend their aid by dealing with the subject in some way in a sermon on that day, and that other forms of celebration, such as towns meetings, lectures or exhibitions, will subsequently take place.

As has been pointed out, we have no desire to do anything that may be termed sensational, but desire by steady and continued work to lead the public, not only in 1912, but in future years, to bear in mind what can be done by a united effort, in removing those hindrances to the enjoyment of good health which are still only too evident.

I am, Sir, yours faithfully,

A. BOSTOCK HILL,
Chairman of the National Health Week Committee.

Temple-street, Birmingham, March 22nd, 1912.

CÆSAREAN SECTION FOR DOUBLE MONSTROSITY.

To the Editor of THE LANCET.

SIR,—I think the following case worthy of publication for two reasons: (1) So far as I can discover, Cæsarean section has not been performed previously for the same condition; (2) the condition of the child, or monster, seems to be a new, though necessarily very rare, indication for the operation.

The patient, 39 years of age, had already had four normal pregnancies, and the youngest child was 11 years old. When I first saw her she had been in labour for 30 hours. A foot had been presenting at the vulva for two hours but the labour pains had been poor. She was under an anæsthetic when I arrived; her pulse was 140 and very feeble. A rapid examination convinced me that no intra-uterine interference could be finished quickly enough to ensure the patient's safety, and I decided to approach the uterus through the abdominal wall. On opening the peritoneal cavity the uterus was pulled well forward, and was thoroughly packed off from it with sterile towels. A fairly free incision was made into the uterus, and a dead double male monster was delivered with some difficulty as the hips were jammed in the pelvis. The placenta was detached, the interior of the uterus swabbed with double cyanide gauze, and the wound sewn up first with interrupted mattress sutures, then with a continuous peritoneal suture. The abdominal wall was closed in the usual way. The patient made an uninterrupted recovery.

The monster proved to be of the thoracopagus variety, the junction extending in length from the manubrium sterni to below the umbilicus, and in width from one side of the body to the other, quite unlike the flimsy junction which seems to be the rule in these monstrosities. A glance at the specimen assured me that under the circumstances embryotomy would have been much the more dangerous expedient to adopt. The specimen weighed 14 lb., and is now in the Museum of the Royal College of Surgeons.

I searched the following literature but failed to find a case which required similar treatment: (1) "Monster (Double)," U.S. Surgeon-General's Index Catalogue; (2) "Monsters," in the General Index, Transactions of the Obstetrical Society of London; (3) "Cases of Abdominal Cæsarean Section," collected by Dr. Amand Routh; (4) "On the Mechanism and Management of Delivery in cases of Double Monstrosity," W. S. Playfair, Transactions of the Obstetrical Society, 1866; (5) "Index Medicus," 1909–1910: Smith, "The Relative Indications for Cæsarean Section," *Ohio Medical Journal*, 1908; R. E. Webster, "Cæsarean Section," *Montreal Medical Journal*; A. C. Buist, "Cæsarean Section with Unusual Indications," *British Medical Journal*, 1909.

I am, Sir, yours faithfully,

St. Leonards-on-Sea, March 21st, 1912. DAVID LIGAT.

THE PRESCRIPTION OF TUBERCULIN.

To the Editor of THE LANCET.

SIR,—It is to be regretted that Mr. Squire's advocacy for expressing the dose of tuberculin in fractions of a c.c. has not been more vigorously controverted in England.[1] All tuberculins are either solutions or suspensions in water of one or more solid chemical principles. If we consider how such a substance as T.R. is produced the conclusion is forced upon us that it is highly improbable that an identical amount of solid extract is obtained from every 10 mg. or multiple of 10 mg. of tubercle bacilli; it is not probable that every c.c. of T.R. purchased will contain an identical amount of the active principle. The amount may be approximately similar, but it will not be identical. For instance, it will vary with the length of time the bacilli have been triturated and with the force of trituration.

[1] THE LANCET, Jan. 6th, 1912, p. 57.

As physicians we are concerned, not with the amount of the solvent used, but with the amount of the active principle in each c.c. of the solvent. The same criticism applies to emulsions. We wish to know exactly how much solid substance is held in suspension and solution in each c.c. of the particular preparation.

The original preparations of tuberculin are not accurate standard solutions comparable with normal soda solutions, nor are they volatile fluids like alcohol or ether, the dose of which may be correctly estimated by fluid measure.

It would be of considerable advantage to the practising physician if all manufacturers of tuberculin would adopt a uniform principle for the standardisation of tuberculin, and the standard should be this—namely, that 1 c.c. of every variety of concentrated tuberculin should contain 1 mg. of solid residue. I had hoped that this suggestion would have been discussed and recommended by the medical congress which was held in Sydney last year, but there was so much business for congress to transact that no time could be given to the matter. During last year I injected not less than 2000 doses of tuberculin, and I have found that the preparations of concentrated tuberculin T.R. obtained from different manufacturers do not always contain the same amount of solid residue. Therefore the results from the use of tuberculin by different clinicians cannot safely be compared so long as we estimate the dose of tuberculin by fluid measure. If tuberculin solution could be physiologically standardised like infusion of digitalis the difficulty could be removed. At present the only safe method is to express the dose in decimal fractions of milligrammes solid substance. I should further advocate that doses of tuberculin less than 1 mg. be registered in negative powers of 10 rather than in ordinary decimals. Thus 0·1 mg. is 10 to the power of minus 1 (10^{-1}), 0·01 mg. is 10 to the power of minus 2 (10^{-2}). 0·05 is 5×10^{-2}. The advantage of this method is that one is less liable to confuse the doses; thus the doses marked respectively 10^{-4} and 10^{-5} mg. are less readily confused than they would be if marked 0·0001 mg. and 0·00001 mg.

I am, Sir, yours faithfully.

C. REISSMANN, M.D., M.R.C.P.,
Physician, Kalyra Sanatorium; Honorary Physician, Consumption Department, Adelaide Hospital; and Lecturer, Forensic Medicine, University of Adelaide.

Adelaide, S.A., Feb. 22nd, 1912.

THE CAUSATION OF TOXIC SYMPTOMS FOLLOWING THE ADMINISTRATION OF SALVARSAN.

To the Editor of THE LANCET.

SIR,—We fully admit the justice of Dr. McIntosh's statement that it is difficult whilst a paper is being read to follow all the points raised. He cannot, however, have forgotten that in the paper referred to we again described the simple control experiments we had already published[1] in detail in December, 1911. These experiments showed that injection of water or saline found to be practically bacteria-free often produces high fever. If these experiments were good experiments the value of the contention that salvarsan fever (not including fever in acute secondary cases) is necessarily due to the presence in the solutions of large numbers of organisms at once vanishes. Until, therefore, these experiments are repeated, and their accuracy tested, Dr. McIntosh is scarcely in a position to dispute our statement as to the frequent possession of pyrogenetic properties by sterile saline. The objection that our later experiments cannot be studied in detail till their appearance in print surely does not justify him in ignoring experiments published in full three months ago—experiments that, if good, are clearly fatal to his views.

We are, Sir, yours faithfully,

E. C. HORT,
W. J. PENFOLD.

Harley-street, W., March 22nd, 1912.

PNEUMOSAN AS A REMEDY FOR TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—It is with great diffidence that I make some remarks on this preparation, and I say at once that my sole reason for so doing is the desire to bring before the medical profession my own genuine experiences in the use of the preparation. I am confronted by the fact that for centuries physicians have endeavoured to find a cure for tuberculosis. The remedies are legion, and many have proved utterly futile upon trial, consequently I feel that any comments on a new remedy should be made very guardedly, and that in reporting any result from its use the bare facts alone should be stated.

The alternative to sanatorium treatment, with its different indications for different cases, is at present tuberculin injections, but that they are liable to be dangerous and have many limitations has been asserted by undeniable authority, a view which I have held all along. The early cases with no breaking down and no mixed infection, the very cases, in fact, best treated by tuberculin, are fairly easily cured by sanatorium treatment without risk, by a treatment, in other words, of lung asepsis or lung hygiene, which prevents, or should prevent, the formation of secondary infections, and in some cases will clear up early cases of mixed infection. Undoubtedly the chief danger we have to meet are the secondary infections. Vaccines and serums in these cases hold a very valuable place in the treatment of pulmonary tuberculosis. Their use, however, is limited to a few, mainly on account of expense, time, the difficulty of handling, the expert bacteriological care required in their manufacture, the susceptibility of the patient to their action, and the fact that the practitioner must always be on the alert, and in constant attendance on the patient. To the busy general practitioner this is not possible.

A preparation which might have a direct action on the pathogenic organisms in the lungs would therefore be of such great value that if any evidence in favour of such a preparation is forthcoming I think it should be given a trial. A medical friend of mine brought pneumosan to my notice and I commenced to use it with an open mind and expecting no great results. I determined to accept nothing but hard facts patent to everyone, and more especially patent to the patients themselves. I hold no brief for pneumosan. I did not know of its existence until it was recommended to me. I am purely interested in it from a medical point of view in connexion with the treatment of pulmonary tuberculosis. Pneumosan, according to the description of its inventor, Dr. Caesare Ballabene, is an amyl-thio-trimethylene compound which destroys the bacillus of Koch in the foci, this being testified to by the abatement of fever and the opsonic index rising; through the amylic compounds the nervous system is helped and the appetite improved; and good dietetic and hygienic regimen completes the cure. The preparation is given by intra-muscular injections. The dosage is from four to ten minims, then a rest of two days is given; then the same dose is followed by three weeks' rest, and then another series of ten injections is given. This may be followed by a fourth or fifth series of injections if necessary—in fact, the number is not limited. The gluteal or scapular region is recommended, but I have used the deltoid region as more convenient for injection.

My experience tends to confirm what is claimed for pneumosan. I am unable to state that it cures tuberculosis, if only because sufficient time has not yet elapsed in my cases to justify such a statement. I have given the preparation in some 50 cases. In no instance has any harm resulted, and no irritation has occurred at the site of injection. In the advanced cases I had some striking results. A bad laryngeal case with pulmonary cavitation was enabled to get up after a few injections, having been in bed for five weeks with fever, the temperature gradually coming to normal. The expectoration diminished, and bad night sweats ceased. The weight gained was satisfactory. The pulmonary physical signs improved, but no change in the larynx was seen, although as the general condition was so improving probably the larynx was too, only imperceptibly. In another case who was fast losing ground, with cavitation and rapid breaking down, also ulceration of the left vocal cord, fever, and night sweats, the patient commenced to hold her own after the first series of pneumosan, her general condition improved, weight

was gained, night sweats ceased, and the morbid processes in the lung and larynx seemed to become controlled. Her general condition so improved that finally this patient could walk three miles comfortably. All the advanced cases except two made much the same progress as the above; one of the unsuccessful cases was complicated by diarrhœa, and the treatment was discontinued before the third series of injections. In cases of the first and second stages, with mixed infection in some, I have noticed the best results—namely, improved appetite, weight gain, night-sweats cease in nearly every instance, cough is lessened, and expectoration diminished, and to quote the words of the patients themselves: "They feel better, eat better, sleep better, and have an increased sense of well being." It has never been claimed for pneumosan that it is an absolute and positive cure for every case of tuberculosis, but my experience it that it does good, and that with its help improvemens may ensue even in advanced cases. Therefore I think it deserves serious consideration and careful trial from members of the medical profession. In judging results, however, it must be borne in mind that all my patients injected with pneumosan were carrying out strict sanatorium treatment.

I am, Sir, yours faithfully,

J. PENN MILTON, M.R.C.S. Eng., L.R.C.P. Lond.,
Honorary Physician, Plymouth Public Dispensary; late Medical Partner to Dr. Otto Walther, Nordrach-Colonie, Black Forest, Germany; and Medical Superintendent to the Devon and Cornwall Sanatorium.
Udal Torre Sanatorium, Yelverton, R.S.O., S. Devon, March 18th, 1912.

THE "CHOLERA BELT."

To the Editor of THE LANCET.

SIR,—As an old Indian practitioner I have been interested in reading the notices of two recent works on disease prevention in India that have recently appeared in your columns. In one of these I see it stated that the authors do not recommend the use of the so-called cholera belt as a preventive measure against either cholera or dysentery. With your permission I should like to draw attention to the question of this "cholera belt." In their work on Tropical Hygiene, Sir C. Lukis and Major R. J. Blackham advise certain preventive measures to be taken in regard to cholera and dysentery; in neither case do they advise the protection of the abdomen by wearing a flannel belt, as used to be the custom in former days. In discussing the subject of clothing (p. 85) their opinion is that it is of little value for this purpose. Yet they advise its use at night, and point out that chill often leads to diarrhœa or dysentery. If it protects from chill at night, why not also by day? The liability to contract chill after exercise, whether on the parade ground or at polo, is undoubted. Lieutenant-Colonel P. Hehir, on the other hand, strongly recommends the belt, "at the risk of being considered old-fashioned"[1]; he states that it maintains an equilibrium in the circulation around the organs most likely to be affected by changes of temperature. He says that many British officers consider it a fad. What is the opinion of Indian officers? With the light clothing that is invariably worn during the hot season in a tropical climate, and the considerable perspiration that results on slight exertion, there is surely need for specially protecting the liver and abdominal organs generally, both by day and by night. The name is perhaps an unfortunate one, but from a physiological point of view to guard against sudden internal congestion of the liver and bowels from chill to the abdominal surface appears to be a sound principle. It would be interesting to learn if there is any scientific reason for the disuse of what, until a few years ago, was recognised as a useful measure of protection.

I am, Sir, yours faithfully,

March 18th, 1912. ANGLO-INDIAN.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—Why do not the advocates of payment for work done tell us how they would deal with the two great obstacles to the system they propose? I allude to overcharge by doctors and bookkeeping. As regards the first, I suppose they would insist on an adequate fee; shall we say 2*s.* 6*d.* a visit? And I suppose, too, the doctor must have the right to say how often he must visit his patient? He cannot possibly submit to any committee or other body saying he shall only go, or at any rate only be paid for, so many visits in a certain time. If this is granted the rest follows. I have at present six club patients permanently on the sick list, every one of whom would be glad to see me daily; they would be worth £273 per annum under that scale of pay. Even the humble shilling would yield £109 per annum.

What I venture to submit as the second objection—bookkeeping—has not, so far as I know, been suggested hitherto. I presume that a detailed account would have to be sent in to the Insurance Committee for every patient attended. The account would certainly have to be in a particular form to allow of checking. It would probably be a rule that all accounts would have to be sent in within a limited time—say a month—of becoming due. (This would be necessary; otherwise it would be impossible for the office to keep the books accurately, and confusion would arise from removals and lapses.) Any departure from the prescribed rates, such as extra visits, mileage, night calls, would have to be duly explained in such a way as to satisfy a Government auditor.

Let the advocates of payment for work done think what it means to keep medical books from day to day in such a manner that accounts such as these can be sent out. No A B C method or abridged system of any kind will do; nothing short of full day-book and ledger would meet it. Think, too, of copying out 400 or 500 such accounts positively during the first month of every quarter, and then, too, think of the correspondence that would follow—e.g., "John Smith, Timbuctoo-terrace, we cannot trace, he is not on your list"; "Your charge of 1*s.* mileage is disallowed, the distance by Ordnance map is 1 mile 1759 yards," &c. No, Sir, payment for work done is unattainable, and I venture to submit undesirable.

I am, Sir, yours faithfully,

Leeds, March 23rd, 1912. CHARLES F. SEVILLE, M.B. Lond.

To the Editor of THE LANCET.

SIR,—I should like very briefly to allude to the three letters which appear in THE LANCET of last week under this heading. Mr. George Brown, I believe, voices the opinion of the general practitioner much more accurately than the Council of the British Medical Association has done. Payment for work done *versus* per capita payment has never been put before the medical profession as a clear issue. The Association has, quite wrongly I think, taken it for granted that the latter mode of payment is necessary under certain conditions, and has most unfairly kept the former in the background—*vide* the decision at the last Representative Meeting.

Dr. Hall's contention, "that in view of the falling sickness rate the premium method is the only means by which our incomes can be maintained," is, I think, quite indefensible. I have always thought that our peculiar and pre-eminent claim to the title of an honourable profession consisted in the fact that we are daily, nay hourly, doing all we can to enable our patients to dispense with our services; and surely no greater triumph can be imagined than the advent of that happy day when one doctor will be able to take the place of six or more. In the meantime let us be paid a fair fee for what we do.

Dr. Cook seems to forget that 8*s.* 6*d.* is already paid by the Government for Post Office employees. This is a very "solid reason," such as Dr. Cook seeks, for our demanding "more," seeing that the lives will not be selected ones.

I am, Sir, yours faithfully,

T. CUMING ASKIN, M.D. Dub.

Alderton, Suffolk, March 25th, 1912.

To the Editor of THE LANCET.

SIR,—In the current number of THE LANCET two of your correspondents seek information as to the average number of attendances required during the year by a member of a club. I doubt if any records of numbers sufficiently large to be reliable in striking an average are to be found, but data sufficient to form the basis of a rough estimate exist scattered through the pages of your "Battle of the Clubs."

First as to generalities, frequent mention is made of the amounts paid by different clubs to their medical officers. These sums vary from 2*s.* to 4*s.* 4*d.* per annum, the most usual sum paid being 3*s.* 6*d.* The average amount paid per

[1] Prevention of Disease and Inefficiency, p. 375.

visit is referred to as being from 1¼*d.* to 8*d.*, the figures most frequently quoted being 2*d.* to 3*d.* If we take 3*s.* 6*d.* as the mean subscription per head per annum and 4*d.* as the mean value per visit, this gives 10·5 visits per member per annum.

In certain cases the actual numbers of members of clubs and the consultations given and visits paid are stated. These numbers when totalled amount to 52,551 members who required 226,446 attendances, or an average of 4·30 attendances per member. These numbers are not absolutely correct, for in the case of Hull the numbers are only given in round thousands, and in the case of Northampton the number of members is an estimate only. The difference in result between these two methods of calculating is somewhat large, but it is probable that the true average lies somewhere between the two, and probably nearer to the lower figure than the higher, and it would probably be safe to put the number at six visits per member per annum.

In order to pay 2*s.* 6*d.* per visit on this basis the capitation fee would have to be 15*s.*

I am, Sir, yours faithfully,

Ramsgate, March 25th, 1912. FRANK MILTON.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Need and Advantages of "School Clinics."

AT the annual meeting of the Manchester, Salford, and District Branch of the National Union of Woman Workers, which was held in Manchester on March 19th, interesting papers on school clinics were read. Miss McMillan, speaking on "Education and Nurture," said that the need for school clinics rested on the fact that the majority of the children of working people were not sufficiently nurtured. This was not entirely due to poverty, but partly to the condition of industrial life in this country, which had devastated home life and destroyed the arts and crafts of motherhood. School clinics, said Miss McMillan, provide a new agency in substitution to some extent for the private nursery. Mr. R. H. Tawney, in the course of an address on "School Clinics," pointed out that we are putting an impossible task on the teachers when we send the children to school in an unhealthy condition. The Manchester school returns showed that one-third of the children had defective eyesight at the school-leaving age. These diseases increased between 5 and 13, and it was obvious that this evil was not to be remedied by leaving it alone. In the majority of cases the parents were not in a position to secure proper medical advice and treatment, and the only effective way of dealing with the children was to establish school clinics in the city. The cost of two clinics larger than the one at Bradford would not amount to more than $\frac{1}{15}$th to $\frac{1}{18}$th of a penny rate per year. In connexion with the cost there must be taken into account the present heavy loss of grants caused by the absence of children from school through illness—a loss which would be considerably reduced by the work of the clinics.

A conference on "School Clinics," which was largely attended, was held here on March 21st, when Dr. Lewis Williams described the work that is being done in Bradford, and Mr. W. Jones gave an account of what is done in regard to the preservation of the teeth of school children in Cambridge. Manchester so far has not adopted any system of school clinics, chiefly because of the lack of any compensatory grant from the Government. Dr. Williams pointed out that even to the untrained eye it was obvious that a large number of scholars were being allowed to grow up more or less physically deformed, and with the prospect of their future careers seriously threatened by the unenviable possession of one or more of the defects so common during school life—such as defective vision, defective hearing, stammering, spinal curvature, decayed teeth, or adenoids, any of which must interfere with the child's capacity as a wage earner in adult life. Indeed, some defects debarred them entirely from certain occupations. Speaking of the establishment of a school clinic, he asserted that it should be administered by the education authority, if the three following necessary conditions are to be obtained: (1) The submitting of the children to treatment; (2) their regular attendance during treatment; and (3) their speedy return to school after treatment. Mr. Jones stated that bad teeth undermined the health and happiness of 85 per cent. of school children.

Children's Hospital and the Act.

The yearly meeting of subscribers to the Manchester Children's Hospital was held on March 20th, when the annual report was presented. The report states:—

> The passing of the Insurance Act has given rise to much anxiety on the part of voluntary hospitals, because it is feared that charitably disposed persons may think that there is no longer any necessity for their support. When, however, it is realised that on the one hand the medical benefit given by the Act does not in any way meet the cases of the vast majority of the inmates of hospitals, and will not lessen the demands upon or the need for the work of such institutions, while on the other hand the Act does not give the hospitals any right to a share in public funds, it is to be hoped that the stream of private benevolence will not be permanently affected. ..... But whatsoever view may be taken as to general hospitals, it should be remembered that the case as regards children's hospitals is different. They do not cater for insured persons. The Act makes no provision for sick children beyond the possibility that in some consumptive cases the children of insured persons may be admitted to sanatoria. If the support given to such hospitals falls off, children will suffer just as they would have done if the Act had not been passed.

March 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Bequest by Lord Lister to Edinburgh University.

AT the monthly meeting of the Edinburgh University Court, held on March 18th, it was intimated that the late Lord Lister had made certain bequests to the University of Edinburgh. These included the insignia of the Prussian Order of Knighthood and of the English Order of Merit; the medals received since his studentship from the Royal Society and other learned bodies; diplomas, &c., conferred by scientific bodies, and various honorary gifts and distinctions. Among the latter are the caskets containing the freedom of the cities of London, Edinburgh, and Glasgow, and of the Merchant Taylors' Company, and the trowel presented to him when opening a new nurses' home at Montreal, together with his portrait in oils. The Court resolved to record their high appreciation of the bequest as a testimony of Lord Lister's affection for the University and city in which he began his professional career, and of his having chosen the University of Edinburgh as the depository of these memorials of his fame and of his place in history as one of the great benefactors of mankind.

Diploma in Psychiatry.

At the meeting of the Edinburgh University Court, held on March 18th, it was resolved to admit women medical practitioners to the University course on physiology of the brain and nervous system for the diploma in psychiatry.

Royal Edinburgh Hospital for Sick Children.

The fifty-third annual general meeting of the contributors to the Royal Edinburgh Hospital for Sick Children was held on March 20th. The directors' report stated that the indoor cases during the year numbered 2031, as compared with 2034 in 1910. Of these cases 1391 were medical and 640 surgical. In the out-patient department 24,513 cases had been treated, as compared with 28,315 in 1910. The ordinary income was £5987 8*s.* 8*d.*, while the ordinary expenditure had been £8465 17*s.* 7*d.* As regarded the convalescent home the directors were satisfied that the cost of its maintenance, amounting to £777, was more than repaid by the benefit the patients derived from residence there. During the year 179 patients had been sent to the convalescent home from the hospital. The medical report drew attention to the fact that nearly half the out-patients were children under two years of age, which accounted for the fact that fully one-third of the beds in the hospital had to be relegated to the treatment of infants. The staff suggested that it was desirable to consider the advisability of adding a milk depôt to the therapeutic resources of the hospital, and the chairman of the directors, in moving the adoption of the report, pointed out the need for further contributions if the scheme were to be carried out, and a proposed balcony accommodation provided.

Annual Report of the Crichton Royal Institution, Dumfries, for the Year 1911.

At this institution the average daily number on the registers was 865·8. During the year there were 202 admissions, of which 159 were certificated and 38 voluntary patients. Of the cases admitted 25 had had one or more previous attacks of insanity, while 100 were suffering from their first attack of mental disorder. The mean age on admission was 45·2, the youngest being a girl of 15 and the oldest a man of 82. The exciting causes of the attacks, apart from distinctly nervous constitutions, inherited or acquired, were most commonly of the nature of worry, affliction, shock, and similar psychical factors and various antecedent bodily illnesses. It is reported that 35 persons admitted were in fair bodily health, 70 were in poor bodily health, and 20 in a weak physical condition. There were 129 discharges representing 124 persons, 87 of whom had been certificated and 37 voluntary patients. The recovery rate of the certificated patients, based on the receptions, was 47·2 per cent. The forms of mental affection recovered from were chiefly in order of frequency, melancholia, delusional insanity, mania, and confusional insanity. In 74 per cent. of the recoveries the mental illness had lasted in all less than a year. The deaths numbered 43 certificated patients and 2 voluntary boarders; the death-rate of the former, based on the average resident population, was 5·2 per cent. The principal causes of death were affections of the heart in 12 cases, exhaustion from melancholia and mania in 7 cases, senile decay in 5 cases, and general paralysis in 4 cases. Only 2 patients died from tuberculosis. Necropsies were held in 79 per cent. of the deaths. Dr. C. C. Easterbrook, the physician superintendent, writes that it is difficult to say to what extent the far-reaching and unwieldy National Insurance Act, 1911, will apply to the institution. Should the Act apply it will be an egregious burden and hardship, for it will ensure only a modicum of the benefits at present enjoyed by those employed on the permanent staff, the institution officials being pensionable and receiving during illness full wages in addition to medical treatment and attendance, and the wives and children of married men living on the estate being also, during their much more frequent illnesses, attended by the resident medical staff.

March 25th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

High Death-rates in Ireland.

THE death-rates in several Irish towns have reached abnormally high figures in the past few weeks. In the Dublin registration area, for the week ending March 16th, the death-rate was 31·8 per 1000 per annum. Curiously it was less in the city, 31·1, than in some of the suburban townships—Rathmines and Rathgar 36·2, and Kingstown 42·4. In some provincial towns the rates were also very high. Thus, in Ballymena the death-rate reached 36·7, and in Kilkenny 44·6.

Dublin Hospital Sunday Fund.

After some years' falling off the Dublin Hospital Sunday Fund last year realised £3454 6*s.* 9*d.*, an increase of £113 9*s.* over 1910. The hospital football match contributed £100.

Disgraceful Behaviour at Ballinrobe.

At a recent meeting of the Ballinrobe, co. Mayo, Poor-law guardians one of the guardians proposed a motion to rescind an increase of medical salaries passed at a previous meeting. The meeting was packed with visitors armed with sticks, who violently shouted down the medical officer, the Local Government Board inspector, and others who essayed to speak against the motion, which was carried by 14 to 10. If, however, the Local Government Board had sanctioned the increase, it could not legally be altered or reversed.

The Dental Hospital of Ireland.

The annual report of the Dental Hospital of Ireland, issued a few days ago, states that the number of cases treated during the year amounted to 48,370. There were 2183 operations under anæsthetics. The number of students on the roll of the school during the year was 48.

The Insurance Act Lectures.

Some of the lecturers appointed under the Insurance Act to enlighten the public are giving very pleasing, though it may be feared not altogether accurate, information. For instance, at a meeting held in Belfast on Feb. 19th, a paid lecturer stated, according to the local papers, that the Act would provide from the very first sanatorium benefit which would remove at one stroke the whole consumptive population and send them back free from contagious disease in a year, thus relieving the rest of the population from danger of contamination. During 1910 the public health department of the city of Belfast dealt with 1173 cases that were either voluntarily or compulsorily notified as tuberculosis of the lungs It would be a tall order to provide sanatorium treatment for them all; and to say that after a year's residence in a sanatorium they would return "free from contagious disease" is absurd. It shows the nonsense of appointing lecturers to deal with a subject about which their knowledge is nil.

A Libel Case.

In a libel action brought at Belfast Spring Assizes on March 19th and 20th, by a dairyman against the Belfast *Northern Whig*, on account of an article stating that the Belfast Health Committee claimed to have found the cause of the outbreak of diphtheria in the milk coming from a certain farm, and recounting the evidence on which the committee's assertion was made, the jury, after only five minutes' absence, rendered a verdict for the *Northern Whig* with costs.

Down County Infirmary.

From the annual report it appears that the total income for the year ended Dec. 31st, 1911, was £2403 15*s.* 8*d.*, and the expenditure £2444 18*s.* 1*d.*, leaving a balance due of £41 2*s.* 5*d.* During the year 2027 were treated, 716 in hospital, and 1311 in the extern department.

Kitchen used as a Cow-house.

On March 21st, at Newtownstewart petty sessions, a farmer summoned a servant for leaving his work before his period of hired service was completed. The evidence showed that about Feb. 18th one of complainant's cows became sick and was brought into the kitchen, where it calved. It remained there for nine days, when it died. The milk which was sent to the creamery passed through this kitchen, and the servant actually had to sleep in this kitchen. The servant said he had not been in good health, but put up with it as long as he could. The case was dismissed, the defendant being allowed 10*s.* costs. What is the use of veterinary inspectors when such a state of affairs is tolerated?

March 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Struggle against Alcoholism.

ONE of the greatest scourges that afflict the human race in all countries is undoubtedly alcoholism. Every day the struggle against this plague is making greater efforts. France, unfortunately, is especially afflicted, at least in certain regions. For many years this matter has engaged the attention of all those who are interested in public health and in the preservation of the vigour of the race. All means of combating it have been sought for, and undoubtedly the best that has yet presented itself is the limitation of the number of liquor shops. Unfortunately, whenever this question comes up in the Chamber of Deputies, while everyone heartily approves of this limitation, no one dare take the responsibility of putting it to the vote, for the liquor-sellers are particularly influential in politics, so that up to now it has been practically impossible to attack or limit these places. The Chamber of Deputies, having this matter once more before them, has again adjourned the vote upon it. The National League against Alcoholism held a great protest meeting on March 17th, which drew together a large attendance, at which all shades of political opinion

were represented. Professor Debove, a former *doyen* of the Faculty of Medicine, was elected chairman. After many speakers had addressed the meeting, M. Joseph Reinach pointed out that the aim to be sought was not only the limitation of the wine-shops, but also to overcome the misery that engenders alcoholism and the insanitary dwelling and environment that favour its development. A vote of censure was passed on the Chamber of Deputies for failing to come to a decision on the matter.

The Relief of Impoverished or Sick Scientific Workers.

The Duc de Loubat, a member of the Institute, well known for his enlightened and effective pecuniary patronage of scientific work, and to whose generosity, to cite merely one example, the Faculty of Medicine of Paris owed the foundation six years ago of a chair of clinical therapeutics, has given to the Academy of Belles Lettres, of which he is a member, two blocks of securities of an annual value of 3000 francs each, to be devoted to assisting scientists, whose work is temporarily arrested through lack of means or illness.

The Grafting of Transplanted Articulations.

On March 19th M. Tuffier reported to the Academy of Medicine, with radiographic demonstrations, the cases of several patients in whom he had resected the elbow, transplanting therein a partial or total articulation. Among other cases he cited two particularly convincing ones. One patient, aged 23 years, had had an elbow-joint entirely useless from ankylosis for two years. M. Tuffier resected the ankylosis and made a new elbow with a tibio-tarsal articulation removed from the amputated limb of a woman. Now, 13 months later, the patient was making use of his transplanted articulation. In the second case, a young man, aged 21 years, had the same operation performed for serious tuberculosis of the elbow. For 14 months the result had proved perfect, the new articulation preserving both its form and its function.

Hospital Abuse.

For many years past the medical profession in France has been protesting against the ease with which patients in comfortable circumstances obtain gratuitous treatment in the hospitals, doing thus a double injury, not only to the Assistance Publique which they could pay for services, and to the really poor whom they deprive of their places in the hospital service, but also to the medical practitioners whom they thus deprive of a *clientèle* perfectly able to pay fees. Everyone is aware of it, yet in spite of that it seems very difficult to prevent this abuse. The Syndicate of French Oculists has dealt with the matter in a very effective manner. A man comfortably well off was operated on gratuitously for cataract in the ophthalmological department of a hospital. This fact becoming known to the Syndicate of Oculists, the latter made an energetic protest to the director of the hospital establishment, who, after an inquiry that fully established the patient's circumstances, with the authority of the Minister of the Interior, demanded the payment of 1000 francs damages. To avoid the prosecution with which he was threatened the patient had to pay the 1000 francs. The Minister of the Interior, recognising the wrong inflicted on the medical body, authorised the director of the hospital to pay over 500 francs to the treasury of the Syndicate of Oculists.

A Medical Committee of Aviation.

A medical committee of aviation has been formed, the honorary president of which is Dr. Reymond, a senator, who has himself made several flights in an aeroplane. Many well-known medical men are members of the committee. The secretary is M. Lepaitre. An appeal is to be issued to all French medical men.

March 25th.

A BRONZE memorial tablet to the late Dr. Leonard Strong McManus has been affixed to the wall of the Battersea Dispensary for Consumption. The inscription reads: "Leonard Strong McManus, 1857–1911. This tablet was erected by public subscription in memory of his kindness to the sick and poor and his untiring efforts to establish in Battersea a dispensary for the prevention of consumption and other forms of tuberculosis."

Obituary.

JAMES BLAKE MAURICE, M.D. ST. AND., F.R.C.S. ENG.

A VERY notable figure in the medical and social world of North Wilts passed away on Feb. 14th last, when Dr. James Blake Maurice died at Lloran House, Marlborough, the house in which he was born 72 years ago. Educated at Cheltenham College, he entered St. Mary's Hospital, London, and became M.D. St. Andrews, F.R.C.S. Eng., and L.S.A. Lond. Having declined the post of surgical registrar at St. Mary's which was offered to him, he joined his father at Marlborough in the practice which his grandfather had first established, and entered on the career which for the next 50 years was to make his name widely familiar in the locality. Over a wide area in North Wilts his opinion was soon eagerly sought, both as practitioner and as consultant. He was an excellent operator, possessing sound judgment and manual skill of a high order. A long series of successful cases of fracture of the elbow-joint treated in the flexed position without splints—a method he had learnt from his father—displayed him again as a skilled surgeon. He had great medical acumen, and was the happy possessor of a highly developed clinical instinct, which often enabled him to come to a sound conclusion as to the patient's condition, by what appeared to be hardly more than a cursory glance. He had the power of inspiring confidence in his patients, and possessed a great store of common-sense. Over and above his purely professional duties, he had many interests, being a man of affairs, with an extraordinarily wide and varied knowledge of men and things.

The medical officer of Marlborough College, Dr. Edward Penny, informs us that during the last quarter of a century, whenever difficulty or danger has arisen to the health of the school he has been accustomed to turn to Dr. Maurice for help and advice, always freely and generously placed at his disposal, "to the great advantage of himself and to the still greater advantage of the school."

For 30 years Dr. Maurice served in the Royal Wiltshire Yeomanry; for 45 years he belonged to the Marlborough corporation, being mayor four times; for 35 years he was a borough magistrate; and for 30 years a county magistrate, besides holding other important public offices. He was surgeon to the Savernake Cottage Hospital, one of the first cottage hospitals to be established in England, in the founding of which he had taken a large share. Happy in so much, Dr. Maurice was above all happy in his family life. He married the daughter of Mr. Nathaniel Kindersley, of the Indian Civil Service, who, together with 12 of his 13 children, survive him. Four of his sons are members of his own profession.

The funeral in Preshute churchyard was attended by the largest and most representative body of people who had gathered on a similar occasion in the neighbourhood within living memory.

EDWARD MASON WRENCH, M.V.O., F.R.C.S. ENG., J.P.,

CONSULTING SURGEON, WHITWORTH HOSPITAL, DARLEY; LATE SURGEON-LIEUTENANT-COLONEL (V.D.) 2ND V.B. DERBYSHIRE REGIMENT.

WE regret to record the sudden death from heart failure of Surgeon-Lieutenant-Colonel E. M. Wrench, a Crimea and Mutiny veteran, who was very well known and greatly respected in the district around Chatsworth. Mr. Wrench was born in 1834 and was the son of the Rev. T. W. Wrench, vicar of St. Michael's, Cornhill, London. He studied medicine at St. Thomas's Hospital and qualified M.R.C.S. and L.S.A. in 1854, and in the same year joined the army in the Crimea as assistant surgeon to the 34th Regiment of Foot. After hospital service at Balaclava he was on trench duty at the front, and in connexion with the attack on the Redan was mentioned in despatches for courage, coolness, and professional skill. In 1856 he was gazetted to the 12th Lancers and served with them in the Indian Mutiny, for which also he received the medal and clasp. Mr. Wrench retired from the army in 1862 and settled in practice at Baslow. He soon joined the 2nd Battalion Derbyshire Volunteers and was eventually promoted Surgeon-Lieutenant-Colonel in 1892, and received the Volunteer Decoration in 1893. He was very popular as

a medical man, and remained in active practice up to the last. He obtained the Fellowship of the Royal College of Surgeons in 1870. Mr. Wrench was friend and medical adviser to the last three Dukes of Devonshire, and attended King Edward when a visitor at Chatsworth, and was decorated by the late King with the Victorian Order. He was consulting surgeon to the Whitworth Hospital, Darley Dale, and a justice of the peace for Derbyshire. His tastes were varied and his interests wide. Latterly he was subject to heart attacks, and his death occurred whilst he was cycling home from Buxton. He leaves a wife and three sons, one of whom is in medical practice in Durham. He will be greatly missed throughout the countryside.

JAMES FRANCIS RYMER, M.R.C.S. ENG.

NEWS has lately reached England of the death on Jan. 11th at Fort Resolution, Great Slave Lake, in North-West Canada, of Mr. James Francis Rymer, who was the first fully qualified English medical man to take up residence and carry on professional work within the Arctic Circle. Studying at Guy's Hospital he qualified M.R.C.S. and L.D.S. in 1887 and obtained an American dental degree in 1892. He resided at Brighton for some years and was honorary surgeon to the Brighton, Hove, and Preston Dental Hospital and medical officer to the Carthusian monastery at Cowfold. In 1907 Mr. Rymer carried out an examination of the teeth of the children attending the elementary schools of the town, and his report called forth from Dr. Arthur Newsholme, then medical officer of health of Brighton, the following statement to the education authority: "The town of Brighton owes a debt of gratitude to Mr. Rymer for this excellent piece of work." In December, 1907, Mr. Rymer sailed for Canada and settled at Edmonton, and in the following June he set out for Fort Resolution on his journey to Fort Good Hope, a distance of 2000 miles. Mr. Rymer wrote *en route*: "I was still busy tending the poor Indians at every station; phthisis, scrofula, and other diseases being common and carrying off yearly large numbers. From Providence to the Arctic Circle these people had never seen a doctor, and I was hailed with marks of affection. My pay was in skins, there being no money in circulation in the North." It was at Fort Resolution, while attending a suffering Indian, that he passed away suddenly.

RICHARD ARTHUR PRICHARD, M.R.C.S. ENG., L.R.C.P. EDIN., J.P.

BY the death of Mr. R. Arthur Prichard, which occurred on Monday, March 11th, there was lost to Conway and the North Wales district a prominent and popular citizen. Born at Pwllheli, Mr. Prichard was educated by an uncle, and after serving articles in Portmadoc qualified in 1867 as M.R.C.S. Eng. and L.R.C.P. Edin. He settled in Conway in 1868, and soon acquired an extensive practice, while he also took a great interest in the affairs of the corporation, serving as mayor of the ancient borough of Conway on no less than six occasions. He was an ardent Freemason. In 1909 he was presented by the community with a handsome motor-car as a testimonial from Carnarvonshire, and especially from Conway, in recognition of his long and arduous public work, the extensive nature of his sympathies, and his sound judgment. He was 69 years of age at his death, and at the funeral, which took place on March 15th, all the places of business were closed during the afternoon.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Max Mandelstamm, of Kieff, who, but for his being a Jew, would have been an "ordinary" or full professor in a Russian university. Being thus disqualified, he had to content himself with a mere title as professor. He had, however, an immense practice, and was a leading spirit amongst his co-religionists of the Zionist party. He was born in the government of Kovno in 1838, and received his medical education in the Universities of Iurieff (Dorpat) and Kharkof, where he qualified in 1860. He practised for some years in Russia, but afterwards went to Germany, where he studied under von Graefe in Berlin and under Helmholtz in Heidelberg. He held an appointment as ophthalmic surgeon to a hospital in Wiesbaden, and returned to Russia in 1868, settling in the university town of Kieff, where he became head of the Ophthalmic Clinic, and was repeatedly elected to the chair, but his election was barred by his religious persuasion.—Dr. Ernst Löhlein, senior surgeon of the Lazarus Hospital, Berlin, from influenza, aged 55.—Dr. Wilhelm Doenitz, of the Berlin Institute of Infectious Diseases, aged 73. After graduating and holding various appointments in Berlin, he was appointed by the Japanese Government in 1872 to organise their newly established medical school and the sanitary department. After his return to Germany he applied himself specially to the investigation and treatment of infectious diseases under Robert Koch in Berlin. From thence he went to the institute for serum preparation at Steglitz. In 1899 he followed Brieger as chief of the infectious disease department of the institute in Berlin. Tropical hygiene has much to thank him for, as he was an accomplished entomologist. He also enriched the science of anthropology by many observations on Eastern Asiatic peoples while he was resident in Japan.—Dr. Paul Bourgeois, formerly deputy for La Vendée.—Dr. Fletcher Powell, formerly professor of pathological anatomy in the Washington University Medical School, Baltimore.

THE NATIONAL INSURANCE ACT.

THE ACTION OF THE UNIVERSITIES AND CORPORATIONS.

AT a fully attended meeting of representatives of the Medical Faculties of the English Universities, of the Royal College of Physicians of London, of the Royal College of Surgeons of England, and of the Society of Apothecaries of London, held at the Royal College of Physicians on March 21st, the following resolution was passed unanimously:—

That this conference, in which are represented the Medical Faculties of the Universities of England and Wales, the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries, recognises that there is a remarkable unanimity of opinion within the medical profession as to the attitude which its members should adopt towards the working of the National Insurance Act of 1911.

This conference desires to place on record its general approval of the principles which inspire that attitude, and while conscious that there is some difference of opinion with regard to details, expresses its willingness to support the demand that these principles should be recognised by those who are responsible for the administration of the Act before medical practitioners consent to work under it.

NATIONAL MEDICAL UNION.

The National Medical Union held a general meeting in Manchester on March 26th. The officers of the Union and a general committee were elected. The general committee subsequently elected an executive which has to report to the general committee once a month, and the general committee will report to the Union at least once in three months. The Union is the outcome of the mass meetings held in Manchester last November and December, and the policy then enunciated was unanimously reaffirmed at the meeting.

A resolution was passed to further support the members of the British Medical Association in their determination to secure the minimum demands of the profession, and approving of the action of the Representative meeting in so far as it carried out the policy of the Union; but the meeting expressed its regret that an advisory committee had been prematurely appointed and allowed to confer with the Commissioners. An instruction was given to the organising committee to influence as far as possible the elections throughout the country for the Representatives and Council of the British Medical Association by securing men who are in sympathy with the objects of the Union.

A committee of the Union is at present dealing with the subject of club and contract practice and preparing a scheme to meet this danger which will arise in the near future.

Dr. T. Arthur Helme has retired from active participation in the work of the Union on account of his health. The error that has appeared in certain quarters that he is the originator of the Union should now be corrected to prevent any misunderstanding.

Dr. Lionel J. Picton, of Holmes Chapel, read a paper on a suggested scheme of medical benefit under an Insurance

Act. The lecturer was cordially thanked for the trouble he had taken in propounding the scheme. At the close of the meeting Mr. William Coates, vice-chairman, asked all country members to become apostles of the Union.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in March the following candidates passed in the subjects indicated:—

Surgery.—W. G. Fraser (Sections I. and II.), McGill; J. Leach (Sections I. and II.), Manchester; and P. McGinnis (Sections I. and II.), Dublin.
Medicine.—H. Cox (Section I.), Birmingham; J. Leach (Sections I. and II.), Manchester, M. J. E. R. Le Dentu (Section II.), Bordeaux; G. Meyer (Section II.), Graz; and R. A. Robinson, Liverpool.
Forensic Medicine.—W. G. Fraser, McGill; and J. Leach, Manchester.
Midwifery.—W. G. Fraser, McGill; W. C. Himely, Paris; and J. Leach, Manchester.
The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: W. G. Fraser, J. Leach, M. J. E. R. Le Dentu, and G. Meyer.

UNIVERSITY OF LIVERPOOL.—At examinations held in March the following candidates were successful:—

DEGREES OF M.B. AND CH.B.

Second Examination.—Part A.: H. G. Bywater, B. J. Doyle, J. J. K. Pentony and R. Rimmer. Part B.: G. D. Harding and B. Williams.
Final Examination.—Part I.: Maud E. Bateman, F. A. Belam, R. W. Gemmell, A. V. Glendenning, E. B. Marsh, A. C. Mooney, and H. S. Pemberton. Part II.: D. H. Clarke and Kate M. Cowe. Part III.: Ethel M. Baker, R. C. Crooke, A. A. Dear, I C. Edwards, T. B. Evans, N. P. Laing, J. Loudon (Second-class Honours), G. W. Mooney, H. Pierce, H. G. Roberts, and J. A. Tobin.

DEGREE OF B.D.S.

Second Examination.—Part I.: D. C. Grundy, A. E. Meeson, and W. A. Williams.—Part II.: D. C. Grundy and W. A. Williams.
Final Examination.—F. C. Wilkinson (Second-class Honours).

DIPLOMA IN DENTAL SURGERY.

Second Examination.—H. O. Sumerling, W. H. Taylor, and B. Wren.
Third Examination.—E. T. Haworth.
Final Examination.—P. G. Capon, R. N. Lee, and W. Williams.

DIPLOMA IN VETERINARY HYGIENE.

T. Craig and G. G. Howard.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Dr. Walter Cappelle has been recognised as *privat-docent* of Surgery; Dr. Walter Friedboes as *privat-docent* of Dermatology; and Dr. Arthur Seitz as *privat-docent* of Hygiene.—*Breslau:* Dr. Paul Heinrichsdorff has been recognised as *privat-docent* of General Pathology and Pathological Anatomy.—*Clausenburg:* Dr. Desider Veszpremi, *privat-docent* of Pathological Anatomy, has been granted the title of Extraordinary Professor.—*Heidelberg:* Dr. Ludwig Arnsperger, of Carlsruhe, has been granted the title of Extraordinary Professor.—*Königsberg:* Dr. Alfred Nissle has been recognised as *privat-docent* of Bacteriology.—*Munich:* Dr. Hermann Dürck, chief of the Pathological Institute of the Isar Hospital, has been appointed by the Government of Brazil to go out and organise a Pathological Institute, and the Munich municipal authority has granted him leave of absence for that purpose. Dr. Hans Fischer has been recognised as *privat-docent* of Medicine.—*Pisa:* Dr. Giuseppe Mazza, of Modena, has been appointed to the chair of Dermatology.—*Prague (Bohemian University):* Dr. Ottokar Lescher has been recognised as *privat-docent* of Ophthalmology.—*Strasburg:* Dr. Paul Mulzer has been recognised as *privat-docent* of Dermatology; and Dr. Dold as *privat-docent* of Hygiene and Bacteriology.—*Turin:* Dr. Pietro Biardi, of Genoa, has been appointed to the chair of Ophthalmology.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on March 15th, Dr. F. de Havilland Hall being in the chair. The accounts presented showed that the business of the society was progressing favourably. The number of sickness claims received was, as usual at this time of the year, rather large, but as they are nearly all of very short duration the amount disbursed for them was not larger than is expected at this season. The committee examined the report for the year 1911. It is an excellent record and shows that the business of last year was exceptionally good, producing a considerable addition to the invested reserves. These now amount to over £250,000. Prospectuses and all further particulars may be obtained on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

THE University of Glasgow proposes to confer the honorary degree of Doctor of Laws upon, among others, Sir Hector C. Cameron, emeritus professor of clinical surgery in Glasgow University, and Dr. Donald J. Mackintosh, medical superintendent of Glasgow Western Infirmary.

LIVERPOOL EDUCATION COMMITTEE.—The Liverpool education committee recently adopted a recommendation to the city council in support of a school clinic scheme for specific diseases for a year, and referred to a subcommittee a motion to report on the suggested establishment, either at Fazakerley or Allerton, of an open-air school for consumptives.

WESTERN OPHTHALMIC HOSPITAL, MARYLEBONE, W.—Mr. Reginald Carter, in presiding over the annual meeting of the supporters of this hospital, announced that the financial position was most serious. During the past three years there had been deficits amounting to £1000, and the amount owing to the bankers was close upon £3000. The committee was, however, determined to leave no stone unturned to improve matters, and begged for the coöperation of the charitable public in carrying on a work of such supreme importance. Mr. H. A. Dunn, the secretary, had resigned after 14 years' service, and the committee had invited Mr. H. W. Burleigh, secretary of the Hospital for Epilepsy and Paralysis, &c., Maida Vale, to assist them in reorganising the administration of the Western Ophthalmic Hospital, and had appointed him honorary secretary of the hospital for this purpose.

LEEDS GENERAL INFIRMARY: ANNUAL MEETING.—The 144th annual meeting of the General Infirmary at Leeds was held on March 14th, under the chairmanship of Mr. Charles Lupton, who for many years has held the position of honorary treasurer and chairman of the weekly board. There was a good attendance of the subscribers and of the general public, and Mr. Lupton's account of the work of the institution during the 12 months dealt with in the annual report was full of interest, while his expressions of hope as to future developments were encouraging to all the members of the staff, who, while proud of the position of the infirmary among the charitable and teaching institutions of the country, are none the less fully aware of the urgent need for an increase in the accommodation and for greater facilities for conducting the work of some of the departments. It was pointed out that owing to the destructive fire which occurred towards the end of 1910, a fire which put no less than 94 beds out of action, there had been great difficulty in coping with the work. Many beds had been found room for in small rooms which the force of circumstances had converted into wards, but an inevitable diminution in the number of patients treated within the walls of the infirmary had to be noted. This decrease amounted to 370, the total number of admissions being 7124 as compared with 7494 for the previous year. The total number of in-patients amounted to 7524. Though the total number of out-patients showed a slight decrease the actual number of attendances was increased by about 13,000 and amounted to 217,034. Mr. Lupton commented on the increase of the work in the X ray department and on the development of the department of bacteriology and of clinical pathology. Turning to the financial side of the report, things were not so satisfactory. The total expenditure was £3000 in excess of the total income, and had it not been for some £12,000 received in legacies the deficiency would have been by so much greater. Legacies must of necessity be an irregular source of income and could not be relied on. The subscriptions to the King Edward memorial fund amounted to £110,000, and as the original sum mentioned had been £150,000 there was still a sum of £40,000 to be collected. Mr. Lupton again took occasion to impress on those at the meeting that the original sum mentioned was a minimum without which a comprehensive scheme of reconstruction and of extension could not be carried out. He pointed out that an essential part of the scheme was the purchase of land adjoining the infirmary to admit of the necessary buildings, and he was able to say that practically all the necessary land had been acquired. As regards the reconstruction of the infirmary, that was going on steadily; ward after ward was being completely overhauled,

the sanitary arrangements and the heating and lighting being made more efficient.

UNIVERSITY OF BRISTOL: COLSTON SOCIETY.—The subscriptions in connexion with the thirteenth annual dinner of this society held last January, when Sir Arthur Quiller-Couch was principal guest and Sir Isambard Owen president, amounted to £464 10*s*. In February, 1911, the committee of the society handed £900 to the University of Bristol for the furtherance of research, and it has been decided to contribute another £450 to the same object. The society has collected almost £7000 for the encouragement of university education since its foundation in 1900.

LEWES SCHOOL CHILDREN.—The importance and value of the medical inspection of children are gradually being realised by parents in those few places where objections have been raised to attend the inspections and to take any steps to remedy the defects. Lewes, the county town of Sussex, was one of those places where the percentage of objections was high, but the figure has now dropped to 10·9 per cent. No fewer than 800 children in the schools of the town are suffering from some degree of caries of the teeth, and as the magnitude of the work has surpassed the efforts of the existing voluntary agencies a school dentist is to be appointed.

UNIVERSITY OF LIVERPOOL: RETIREMENT OF PROFESSOR DONNAN.—Much regret has been expressed at the retirement from the staff of professors at the University of Professor Donnan, who is to be congratulated upon his appointment as professor of chemistry at University College, London. Professor Donnan has held the chair of physical chemistry in Liverpool since its foundation in the year 1903. In the intervening period he has published the results of researches which have made his name so well known in the field of science; he has received the Fellowship of the Royal Society, and is very popular with his colleagues and his students. The appointment of a successor will be a matter of great responsibility to the Council of the University. As the successor to Sir William Ramsay at University College, Professor Donnan succeeds to a great tradition which, it is felt in Liverpool, he will worthily uphold.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN (UNIVERSITY OF LONDON).—The council has received the sum of £1500 from an anonymous donor to clear off the debt upon the building. It has also received from Mr. H. M. Phipson the sum of £100 to endow a prize in pharmacology in memory, and to bear the name, of the late Dr. Edith Pechey Phipson. The Gilchrist studentship for women of £100 has been awarded by the University of London to Miss Cicely M. Peake, M.B., B.S. Lond., a former student of the school. The St. Dunstan's Medical Exhibition, value £60 per annum for three or five years, and the School Scholarship, value £30, will be awarded on the result of an examination to be held on May 28th and following days. Forms of entry must be sent to the secretary of the school, from whom all particulars can be obtained, before May 20th.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A special meeting of this society will be held, to consider the subject of Rheumatoid Arthritis, on Friday, April 12th, at 8 P.M., at the West London Hospital, W. The following is to be the programme of arrangements: From 8 to 9 P.M. there will be an exhibition of—1. Cases, illustrating (i.) causation, (ii.) joint lesions, (iii.) trophic lesions, (iv.) skin affections, (v.) eye affections, (vi.) diagnosis from—(*a*) tuberculous joints, (*b*) neuropathic joints, (*c*) osteo-arthritic conditions, (*d*) gonococcal arthritis, (*e*) syphilitic arthritis. 2. Skiagrams, illustrating (i.) changes in cartilage, (ii.) changes in bone, and (iii.) deformity. 3. Museum specimens, illustrating (i.) lesions of cartilage, (ii.) lesions of bone, and (iii.) lesions of soft tissue. 4. Bacteria, illustrating (i.) oral sepsis, (ii.) alimentary infection, and (iii.) genital infection. From 9 to 9.45 P.M. there will be short papers and demonstrations, and from 9.45 to 10.30 P.M. a general discussion. The following, among others, have promised to take part in the proceedings: The President (Mr. W. McAdam Eccles), Dr. F. J. Poynton, Dr. T. J. Horder, Dr. Reginald Morton, Mr. Lloyd Williams, Mr. W. J. Midelton, Dr. Bernstein, and Dr. F. S. Palmer. Members and visitors are invited to attend at 8 P.M., as the time for exhibition of cases, &c., is limited.

Parliamentary Intelligence.

Inebriates Bill.

THE terms of the Inebriates Bill recently introduced in the House of Commons by Mr. ELLIS GRIFFITH, supported by the Home Secretary, have been published. The object of the Bill is to consolidate and amend the law relating to inebriates. Part I. deals with provisions as to inebriates not guilty of offences, and includes clauses relating to voluntary submission to restrictions, compulsory orders of committal to retreats, and provisions as to retreats. Part II. is concerned with provisions as to inebriates guilty of offences. This covers the punishment of offences by inebriates and inebriate reformatories. Part III. is general.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 20TH.

Deaths from Uncertified Causes.

Mr. GEORGE GREENWOOD asked the President of the Local Government Board to state the number of deaths of which the causes were not certified in England and Wales in each of the five years 1907 to 1911, inclusive.—Mr. BURNS wrote in reply: The numbers of deaths from uncertified causes are as follows: 1907, 7596; 1908, 7477; 1909, 7021; 1910, 6658; 1911 (provisional), 6666. The term "uncertified cause" here signifies a cause of death not certified either by a registered medical practitioner or by a coroner after inquest.

Vaccination and Small-pox.

Mr. COURTHOPE asked the President of the Local Government Board whether he had received communications from boards of guardians with reference to the danger to the community of an outbreak of small-pox, owing to the increasing tendency of parents to procure exemption from vaccination for their children; and what steps he proposed to take in the matter.—Mr. BURNS furnished the following written reply: The guardians of the Wirral union passed a resolution expressing the view indicated in the question, and sent a copy of the resolution to the other boards of guardians in England and Wales. About 80 of the other boards, some 650 in number, have informed me that they have passed a similar resolution. I do not at present think it necessary to take any steps in the matter.

The Headquarters of London University.

Sir PHILIP MAGNUS asked the Prime Minister whether the Government had appointed a trustee or trustees in connexion with the proposal for providing a site in Bloomsbury for the headquarters of the University of London, and whether the Senate of the University had been informed of the proposal and had expressed any opinion thereon.—Mr. ASQUITH replied: The Government have not appointed a trustee or trustees for the purposes described. A body of trustees is, however, being constituted, one of whom is a member of the Government, to receive gifts offered in connexion with the recommendations of the fourth report of the Royal Commission on University Education in London. A generous gift has been made on condition that a particular site is acquired. The question of its suitability is one affecting the future organisation of the University, a matter on which the Senate has found itself unable to offer any evidence to the Royal Commission.

Sir PHILIP MAGNUS: May I ask the right honourable gentleman to answer the last part of my question?—Mr. ASQUITH: I said that the Senate has found itself unable to offer any evidence to the Royal Commission.

Sir PHILIP MAGNUS: May I take it that the Senate has not been consulted?—Mr. ASQUITH: The honourable gentleman must draw his own conclusions.

THURSDAY, MARCH 21ST.

Inspectors of Boarded-out Children in Ireland.

Mr. BIRRELL (Chief Secretary to the Lord Lieutenant for Ireland), in replying to a question put by Captain CRAIG respecting the religion of the inspectors of boarded-out children in Ireland, said that a lady inspector had been recently appointed an Insurance Commissioner. The Local Government Board for Ireland were anxious for many reasons that this vacancy should be filled by a fully qualified lady doctor, but neither of the Protestant lady doctors who were candidates considered that the salary offered was sufficient to induce them to accept the position.

Registration of Apothecaries' Assistants.

Captain CRAIG asked the Secretary of State for the Home Department whether, in view of the date of the National Insurance Act coming into force, he would state what steps had been taken in conjunction with the Pharmaceutical Society to frame by-laws under Clause 4 (b) of the Pharmacy Act, 1908, for the registration of Army compounders and apothecaries' assistants as chemists.—Mr. MACKENNA answered: I am informed that the Pharmaceutical Society is in communication with the War Office as regards qualified military dispensers and that the question of certified assistants to apothecaries is also receiving the Society's active consideration.

The Report of the Vivisection Commission.

Dr. CHAPPLE asked the Secretary of State for the Home Department whether he would give the cost of the Commission on Vivisection; and whether he would consider the advisability, in future reports, of abstracts of evidence giving the substance only instead of verbatim reports of question and answer being printed, and of the whole being done up in octavo size and book form.—Mr. MCKENNA replied: The expenditure has amounted to about £5674. I fear that mere abstracts of the evidence would not have satisfied the persons and societies who are keenly interested in the subject of vivisection. The question of printing reports is mainly one for the Stationery Office, but I may point out that the number of volumes would be greatly increased if the use of the existing double-columned foolscap page were discontinued.

The Adulteration of Flour.

Sir JOHN LONSDALE asked the President of the Local Government Board whether, having regard to the practice which prevailed of adulterating flour by the addition of various deleterious substances in the process of manufacture, he would direct the special attention of the responsible authorities to the provisions of Section 3 of the Sale of Food and Drugs Act, 1875, with a view to the prosecution of offenders.—Mr. BURNS said, in reply: The question of the adulteration of flour is now under consideration, and I am not at present in a position to state what steps will be taken. The publication of the answer which was recently given to the honourable Member will have drawn attention to the section referred to.

Sir JOHN LONSDALE: The right honourable gentleman has had the matter under consideration fully 12 months.—Mr. BURNS: No longer than is necessary.

Sir JOHN LONSDALE: How much longer will the right honourable gentleman require? I do not wish an evasive answer.

The SPEAKER: No doubt the right honourable gentleman has given the best answer he can.

MONDAY, MARCH 25TH.

Medical Treatment of School Children.

Mr. HAYES FISHER asked the President of the Board of Education whether the sum of £60,000, included in the estimates of the Board of Education under the head of grants towards the expenses of local authorities in respect of medical treatment of school children and services ancillary thereto, represented the full extent of the grant to be given in the year 1912-13 towards the expenses incurred by local authorities in England and Wales for medical inspection and treatment of school children; whether it was proposed to limit the assistance given by the imperial Exchequer to the optional service of medical treatment, leaving local authorities to bear the whole of the compulsory burden of medical inspection; whether he was now prepared to indicate the basis on which the new grant would be distributed; and whether, in allocating the grant, he would take into account the money already expended by a local authority.—Mr. PEASE replied: The answer to the first part of the question is in the affirmative, but the amount to be made ultimately available for the purposes referred to will be considerably in excess of the sum provided in the estimates for the year 1912-13. The answer to the second part of the question is also in the affirmative. In answer to the third part of the question, I hope to be able to issue in a few days' time the regulations under which the grant will be paid, and an explanatory circular. With regard to the last part of the question, in allocating the grant the expenditure of the local education authorities during the previous year will be taken into account.

Medical Benefits.

Mr. CASSEL asked the Secretary to the Treasury when a member of an approved society attained the age of 70 and ceased to pay contributions, would the society still be liable to make the same payments or any payments in respect of such member to the Insurance Committee to provide medical benefits; if not, from what source would the doctor and chemist be paid for medical benefit for such member.—Mr. MASTERMAN answered: The payments made by an approved society to an Insurance Committee for medical benefit will be made on account of all the members of a society and not of any particular member. They will be paid out of the funds of the society as built up by the contributions made in respect of all the members and the reserves accumulated in respect of them.

Preservatives in Cream.

Mr. STANIER asked the President of the Local Government Board whether he would consent to such modifications in the draft regulations for the restriction of the use of preservatives in cream as to provide that the labelling proposals in the regulations could be so modified as to be made commercially workable.—Mr. BURNS answered: The Local Government Board are prepared to receive and consider any representations concerning the proposals in the draft regulations.

Mr. STANIER further asked the right honourable gentleman whether he could see his way to delay the operation of the proposed draft regulations as to preservatives in cream for a month, in order that opportunity might be given to the interested persons to discuss such modifications of the regulations as would enable them to be carried into effect without detriment to the supply to the public of the articles referred to in the regulations.—Mr. BURNS said, in reply: Under the Rules Publication Act, 1893, the Board is required to consider any representations or suggestions which are made in writing by any public body interested before the order is finally settled. Notice of the intention to make regulations was published in the *London Gazette* of Feb. 20th, and the statutory period for the making of such representations or suggestions is 40 days from that date.

TUESDAY, MARCH 26TH.

The Sanitary Commissioner to the Government of India.

Mr. HOGGE asked the Under Secretary of State for India whether there was any intention to appoint a separate Sanitary Commissioner to the Government of India, or whether it was intended to continue the temporary arrangement whereby the Director-General of the Medical Service was at present doing the work in addition to his own.—Mr. MONTAGU answered: The reply to the first question is in the affirmative. Certain questions regarding the functions and position of the Sanitary Commissioner are under consideration. As soon as they are decided the appointment will be made.

The Definition of Vinegar.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether there was in his department any definition or standard of vinegar, based either upon the substances from which it was manufactured or upon the percentage of acetic acid which it contained; and whether, in the absence of a due percentage of the above acid, prosecutions of its vendors under the Food and Drugs Act were authorised by the Board.—Mr. BURNS replied: There is no statutory definition of vinegar for the purposes of the Sale of Food and Drugs Acts, but, in view of the numerous representations made to it on the subject, the Board stated its views as to the proper significance of the terms "vinegar," "malt vinegar," and "artificial vinegar" in a letter addressed to the secretary of the London and County Vinegar Brewers' Association on Dec. 15th last. The Board has no power to authorise prosecutions under the Sale of Food and Drugs Acts.

Workmen's Medical Funds.

Mr. RICHARDS asked the Secretary to the Treasury whether he had received an application from the workmen's medical funds of Monmouthshire that a representative acquainted with workmen's medical funds should be appointed upon the advisory board of the National Insurance Act Commissioners; and whether he proposed to grant such representation.—Mr. MASTERMAN wrote in reply: The answer to both parts of the question is in the affirmative.

WEDNESDAY, MARCH 27TH.

The Adulteration of Flour.

Sir JOHN LONSDALE asked the President of the Local Government Board whether, having regard to the fact that it had been established by departmental investigation that the adulteration of flour by the addition of various deleterious substances was largely practised by millers, and the matter had been under his consideration for more than a year, he could now state when he expected to be in a position to announce the steps to be taken to put a stop to this practice in the public interests.—Mr. BURNS said in reply: I have received a number of deputations on this subject since the reports were issued from my Foods Department last year, and the matter has been carefully considered by my expert advisers from all points of view. As a result, I have come to the conclusion that in some respects the matter can be adequately dealt with by the ordinary law against adulteration. I am, however, still considering whether it may not be possible to deal with some of the practices to which the honourable baronet refers by regulations under the Public Health (Regulations as to Food) Act, 1907.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PUBLIC HEALTH IN BASUTOLAND.

A REPORT from the Acting Resident Commissioner of Basutoland, South Africa, on the annual Blue Book for the territory for the year ending June 30th, 1911, has been received at the Colonial Office and presented to Parliament. It states, *inter alia*, that the population, as ascertained by a Census taken in April and May last, amounted to 402,434—183,241 males and 219,193 females. The general health of the territory has been good and no epidemics of any importance have occurred. Small-pox broke out in the Quthing district, but was confined to one village. The infection was traced to the Cape Province, and steps were immediately taken to secure vaccination of those leaving the country, certificates of vaccination being demanded of those requiring passes. The important subject of leprosy has been under consideration during the past year. Suggestions for the establishment of a leper settlement were laid before a meeting of the Basutoland council; they were most favourably received, and have been generally approved by the High Commissioner for South Africa (Viscount Gladstone). The selection of a suitable site will perhaps prove difficult, but it is hoped that the question will be satisfactorily settled before long. The number of patients treated during the year in the Government hospitals and dispensaries showed a considerable increase over the previous year. The in-patients numbered 1732 and the out-patients 43,961. Of the latter 9500 attended at the dispensaries more than once. During the year the principal medical officer made a tour of inspection of the hospitals and dispensaries throughout the territory, and reported very favourably on the work done, both as regards quantity and efficiency. A small hospital has been opened at Quthing and has been much appreciated in the district.

GIVING WAY.

MR. Hamilton Spratt, who describes himself on his card as a "surgical chiropodist," has been good enough to ask our advice in a delicate professional matter occurring in his practice. He says: "I have a patient who has a split thumb-nail which won't give way to every treatment I have tried. Could someone in your medical staff advise me what to do? I enclose my card." Perhaps the nail would give way if the surgical chiropodist gave way to a medical manicurist.

DEATH FROM SEA-SICKNESS.

AN inquest was held at Newhaven on March 25th on the body of M. Constant Lecamp, a director of the Crédit Industriel de Paris, who died on a cross-Channel boat between Dieppe and Newhaven. He was accompanying his daughter to Brighton, but experiencing a very rough passage suffered severely from sea-sickness. This brought on cardiac failure, death occurring before harbour was reached. There was no medical man aboard the vessel at the time. M. Lecamp, it was stated in evidence, had been attended at home for heart affection.

THE WOMEN'S IMPERIAL HEALTH ASSOCIATION.

THE second annual report of this association for 1911 lies before us. Information concerning the association was given in our columns of March 9th, p. 701. The present report clearly indicates the excellent progress made during the past year. The Florence Nightingale and Aurora Caravans "trekked through the villages, the lecturer giving talks, cinematograph shows, and distributing leaflets, while at intervals of about a fortnight a lecturer came from London to speak in the larger towns included in the tour." A caravan was present at the Festival of Empire, and one also made a tour of the London parks, visiting each of them several times. The association has taken a house in the Kennington-road on lease for its school for mothers. A fête was held in the Royal Botanic Gardens, Regent's Park, on July 5th, under the immediate patronage of the Duke and Duchess of Argyll, Prince Alexander of Teck, and other distinguished persons. The association is agitating for free lavatory accommodation for women. The report contains also much useful hygienic information and household hints. The address of the association is 7, Hanover-square, London, W.

THE LITTLE MOTHER'S SCHOOL.

THE Little Mother's School is an institution established by the Chicago Department of Health. In 31 schools, situated in different parts of the city, a class is held once a week for young girls, where all subjects pertaining to the care and rearing of children are taught. These pupils learn of ventilation and nursery hygiene—how babies should be bathed, dressed, and fed, and how they should be cared for in their sleep. The teaching is given in the simplest terms possible, and the pupils, who already number more than 1000, have certain

opportunities of putting what they have learnt into actual practice. Two nurses are present at each class—one to speak, the other to demonstrate—and pupils are encouraged to bring materials so as to make babies' clothes at the class. The work is all under the direction of the supervising nurses of the Board of Health, School Hygiene Division. The teachers have to attend twice a week at the department headquarters so that they may themselves be taught. Already an examination has been held and the pupils have been called upon to write papers describing the instruction they have received. The following is claimed to be not an exceptional but a fair sample of the papers written by the "Little Mothers." The author is a girl, 14 years old, and she writes:—

> "Health is the condition free from pain, and normal condition of the body. No one can be healthy who does not keep himself clean. Hygiene is the science of health, and to have healthy people we must begin with the baby. Before we bath the baby we should have all the things ready. Then see if the water is not too warm. We try it by putting our elbow in; if we can stand it, it's all right for baby. Then we put towels so the baby's body does not touch the bottom of the bath tub. First of all, we wash its head and hands, then its eyes with a different piece of cotton for each eye, then its feet and body. After we have washed it well, then we take the baby out, and put him on the blankets. We dry it by patting gently, not rubbing roughly."

Apparently the lessons given consist of a counsel of perfection. Very few babies are bathed in this country with such minute care and luxurious provision of blankets and linen. Many British mothers would be more than surprised if called upon to use a fresh and separate piece of wool to wipe each of the baby's eyes. Nevertheless, having undertaken the task of teaching young girls what will be their duties as mothers, it is wise to advise the best methods. This, in any case, leaves a wider margin for those compromises that inevitably take place in the hurry of daily life between the ideal and what is conveniently practical. A somewhat meticulous course of instruction includes the teaching of how to sing a lullaby.

A NOISE-SILENCER.

Sir Ronald Ross has directed our attention to an invention called an earclip, which he made more than 20 years ago for a patient who was very susceptible to slight noises. He has now put the invention on the market with the object of helping medical men in the treatment of patients susceptible to noise. It consists of a horseshoe spring, at the ends of which are wooden studs, which press against the tragus or other part of the ears so as to close them and prevent or partly prevent noises reaching the tympanum. The springiness of the metal horseshoe allows the pressure being made greater or less as desired. The device can be worn when lying down, and it is pointed out that by its use the noises going on in hospitals, factories, offices, railway trains, and steamers, the streets of a city, or from insects in tropical climates, can be wholly or largely excluded from the auditory nerves, and the wearer can obtain comparative or complete silence, and thus be enabled to get sleep or quiet or to concentrate his thoughts on work in hand without distraction. Messrs. C. Baker, 244, High Holborn, are the manufacturers. The price of the silencer is 2*s.* 6*d.*

"*Dumpling*," a medical man, would be glad if any of our readers could, through the columns of THE LANCET, give him information concerning the pay and prospects of a lady dispenser. He wishes to know if this work provides a good opening for a girl, or whether the supply already exceeds the demand.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March and April:—

March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
April 1st and 2nd (Milan).—Italian National Convention upon the Sexual Question.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
" 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 8th–13th (Rome).—Seventh International Congress of Dermatology and Syphilology.
" 8th–15th (Johannesburg).—Thirteenth South African Medical Congress.
" 9th–11th (Paris).—Congress of Physiotherapy for French-speaking Physicians.
April 9th (Berlin).—Eleventh Congress of the German Society for Orthopædic Surgery.
" 9th–13th (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
" 10th–13th (Berlin).—Forty-first Congress of the German Surgical Society.
" 12th–30th (London, Olympia).—Ideal Homes Exhibition.
" 14th (Berlin).—Eighth Congress of the German Röntgen Society.
" 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
" 15th–18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
" 21st–24th (Munich).—Twenty-sixth Meeting of the Anatomical Society.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.
PATHOLOGICAL SECTION (Hon. Secretaries—J. C. G. Ledingham, A. E. Boycott): at 8.30 P.M.
Laboratory Meeting at the Cancer Laboratory, Middlesex Hospital, W.

RÖNTGEN SOCIETY, Institution of Electrical Engineers, Victoria Embankment, W.C.

TUESDAY.—8.15 P.M., Dr. Saubermann: The Physiological Principles of Internal Radium Therapy.—Mr. C. A. Clarke will demonstrate a Device for Viewing Wet Negatives.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Dr. G. N. Meachen: The Relationship between Some of the Commoner Skin Diseases and Systemic Disorders.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. T. C. Fox: Clinique (Skin). 5.15 P.M., Lecture:—Mr. M. Collier: Other Disorders of Impeded Respiration.
TUESDAY.—4 P.M., Dr. J. J. Perkins: Clinique (Medical). 5.15 P.M., Lecture:—Dr. N. Pitt: Adherent Pericardium.
WEDNESDAY.—4 P.M., Mr. G. E. Waugh: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. Taylor: Some Common Nervous Diseases (lantern demonstration).
THURSDAY.—4 P.M., Mr. H. A. T. Fairbank: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. V. Bonney: The Treatment of Displacement of the Uterus and Vagina.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham): Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).
TUESDAY.—Clinic: 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld.); Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).
WEDNESDAY.—Clinics:—2.30 P.M., Demonstration on Fevers (Dr. F. Thomson, at the North-Eastern Fever Hospital, St. Ann's-road, N.); Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Demonstration on Fevers (Dr. F. Thomson; at the North-Eastern Fever Hospital, St. Ann's-road, N.); Gynæcological Operations (Dr. A. H. Giles): Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. H. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

LISTER INSTITUTE OF PREVENTIVE MEDICINE, Lecture Theatre of the Lister Institute, Chelsea Bridge-road, S.W.

TUESDAY.—5 P.M., Dr. W. Nicoll: Modern Aspects of Helminthology—General Morphology and Biology of the Nematodes. (Lecture V.)

SALFORD ROYAL HOSPITAL.

THURSDAY.—4.30 P.M., Mr. J. B. Macalpine: Modern Methods of Diagnosis in Urinary Surgery. (Post-Graduate Course.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.). Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (3rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (4th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (6th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

The following journals, magazines, &c., have been received:—British Journal of Dermatology, Transactions of the Ophthalmological Society of the United Kingdom, Revue de Psychiatrie, Journal d'Urologie, Revue d'Hygiène et de Police Sanitaire, Journal of Nervous and Mental Disease, Kala-azar Bulletin, Annales de l'Institut Pasteur, Philippine Journal of Science, Transactions of the Society of Tropical Medicine and Hygiene, Archives Internationales de Neurologie, Canadian Practitioner, Interstate Medical Journal, Annales de Gynécologie et d'Obstétrique, American Journal of Orthopedic Surgery, Detroit Medical Journal, Archives of Internal Medicine.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Dr. R. Ackerley, Helouan; Dr. T. Cuming Askin, Alderton; Dr. Edwin Ash, Lond.; Dr. H. R. Andrews, Lond.

B.—Brighton, Hove, and Preston Dispensary, Secretary of; Bristol General Hospital, Secretary of; Mr. W. G. Burcombe, Lincoln; Messrs. C. Barker and Co., Lond.; Mr. C. Birchall, Liverpool; British Oxygen Co., Lond., Secretary of; Dr. John Biernacki, Lond.; Buckingham, Medical Officer of Health of; Bolingbroke Hospital, Lond., Secretary of; Mr. E. Baker, Birmingham; Bayer Co., Lond.; Dr. Hugh Barker, Derby; Mr. A. Bishop, Lond.; Surgeon F. G. H. R. Black, R.N., Portsmouth; Dr. E. Farquhar Buzzard, Lond.; Dr. Andrew Balfour, Khartoum; Mr. C. A. Bucklin, Glasgow; Mr. Ernest Bell, Lond.; Mr. J. F. Briscoe, Alton; Sir George T. Beatson, K.C.B., Glasgow; Dr. W. Blair Bell, Liverpool; Bristol Medico-Chirurgical Society, Hon. Secretary of; Messrs. P. Beiersdorf and Co., Lond.

C.—Messrs. Cassell and Co., Lond.; Mr. C. Clarke, Haywards Heath; Coventry and Warwickshire Hospital, Secretary of; Messrs. R. Carruthers and Sons, Inverness; Cheltenham General Hospital, Secretary of; Central London Throat and Ear Hospital, Secretary of; Mr. F. T. Crooke, Pershore; Messrs. J. and A. Churchill, Lond.; C. T. D.; Messrs. Cadbury Bros., Bournville; Croydon Mental Hospital, Warlingham, Clerk to the; Cardiff Port Sanitary Authority, Medical Officer of Health of; Mr. H. Clifford, Manchester; Mr. H. S. Clogg, Lond.; Dr. Cunliffe, Manchester; Messrs. Carfax, Lond.; Sir T. Chavasse, Barnt Green.

D.—Dorland Agency, Lond.; Mr. E. Darke, Kingston-on-Thames; Dr. J. F. Halls Dally, Lond.; Professor Sheridan Delépine, Manchester; "Dumpling"; Dr. Henry K. Dawson, Ashtead; Dr. John Shaw Dunn, Glasgow; Messrs. W. Dawson and Sons, Lond.; Dunelm.

E.—Mr. W. McAdam Eccles, Lond.; Professor W. Einthoven, Lond.

F.—Mr. W. R. Forbes, Lond.; Mr. George P. Forrester, Darmstadt; Dr. Ninian M. Falkiner, Dublin; Mr. T. R. Freeman, Monkton Combe; Dr. R. W. Fell, Buntingford.

G.—Mr. M. Gray, Lond.; Messrs. C. Griffin and Co., Lond.; Guest Hospital, Dudley, Secretary of; Mr. Griffiths, Newport, Monmouthshire; Lieutenant H. Gall, R.A.M.C., Ambala; Mr. Ernest Gunton, Lond.; Dr. Alfred Greenwood, Blackburn; Mr. Haden Guest, Lond.; Mr. F. W. Gamble, Lond.; Dr. Gibson, Oxford; Messrs. W. Grisewood and Son, Liverpool.

H.—Messrs. Hyam and Co., Lond.; "Had some"; Dr. F. W. Hayes, Leeds; Mr. C. A. Hoefftcke, Lond.; Humphreys, Ltd., Lond.; Messrs. A. Hommel and Co., Lond.; Miss Hamilton, Lond.; Professor W. D. Halliburton, Lond.; Dr. E. C. Hort, Lond.; Dr. Bernard Hart, Epsom; Dr. Thomson Henderson, Nottingham; Dr. C. F. Harford, Lond.; Dr. A. Herbert Hart, Lond.; Dr. A. Bostock Hill, Birmingham; Dr. F. Hernaman-Johnson, Bishop Auckland; Mr. Irvine Harle, Lond.; Dr. A. E. Horn, Lond.; Dr. H. W. Hart, Hyères.

I.—The Infant's Hospital, Lond.; Secretary of; Messrs. Iliffe and Sons, Coventry.

J.—Mr. E. T. Jones, Eastmeon; Dr. T. S. Jones, Baton Rouge, U.S.A.

K.—Messrs. R. A. Knight and Co., Lond.; Captain Kenji, Ide, I.J.N., Lond.; Messrs. Kutnow and Co., Lond.

L.—Leeds Corporation, Clerk to the; Loughborough and District General Hospital, Secretary of; Leeds Public Dispensary, Secretary of; Dr. Thomas Lewis, Lond.; London Press Exchange, Lond.; *The Leather World*, Lond., Editor of; London (Royal Free Hospital) School of Medicine for Women, Secretary of; Mr. David Ligat, St. Leonards-on-Sea; Local Government Board, Lond., Medical Officer to the; Dr. R. Leonard Ley, Great Yarmouth; Dr. E. J. Leterle, New York; Local Government Board, Lond., Secretary of; Leicester Infirmary, House Governor and Secretary of; Liverpool Stanley Hospital, Hon. Secretary of.

M.—Messrs. Macmillan and Co., Lond.; Macclesfield General Infirmary, Secretary of; Mullingar District Lunatic Asylum, Clerk to the; "Microscopical"; Medico-Chirurgical Society of Glasgow, Editorial Secretary of; Mr. S. MacIlwaine, Clevedon; The Maxiphone, Ltd., Lond.; Dr. A. Morison, Lond.; Mr. R. Mosse, Berlin; Dr. A. F. McCallum, Cairo; Mr. J. G. O. Moses, Edinburgh; Medical Sickness and Accident Society, Lond., Assistant Secretary of; Dr. R. G. Moon, Lond.; M.D. Cantab.; Dr. Charles Miller, Lond.

N.—Newport and Monmouthshire Hospital, Secretary of; Mr. M. J. Nolan, Downpatrick.

O.—Mr. E. T. Oliver, Torquay; Mr. C. A. P. Osburne, Norwich; Dr. L. R. Oswald, Glasgow.

P.—Prince of Wales's General Hospital, Lond., Secretary of; Plasmon Tea Co., Lond.; Dr. Edward Penny, Marlborough; Dr. C. Yelverton Pearson, Cork; Dr. P. N. Panton, Lond.; "Pater Familias"; *Philippine Journal of Science*, Manila, Business Manager of.

R.—Messrs. Robertson and Scott, Edinburgh; Dr. W. W. Rorke, Lond.; Royal College of Physicians of London, Registrar of; Royal College of Surgeons, Lond., Secretary of; Röntgen Society, Lond., Secretary of; Mr. John Ritchie, jun., Boston; Mr. N. Reader, Wakefield; Dr. R. R. Rentoul, Liverpool; Dr. John Robertson, Birmingham; Dr. W. Ritchie, Glasgow; Royal Microscopical Society, Lond., Secretary of.

S.—Scholastic, Clerical, and Medical Association, Lond.; Seamen's Hospital Society, Lond., Secretary of; Scout Motors, Ltd., Salisbury; Dr. F. W. Saunders, Assouan; Messrs. W. H. Smith and Son, Birmingham; Messrs. Schweppes, Lond.; Messrs. Sharland and Co., Lond.; Smith's Advertising Agency, Lond.; S. F. B.; Sheffield Royal Hospital, Secretary of; Dr. T. C. Somerville, Manchester; Dr. T. H. Suffern, Onitcha; *Shrewsbury Chronicle*, Manager of; Dr. A. Sayba, Cairo; Messrs. Schimmel and Co., Lond.; Messrs. W. H. Smith and Son, Lond.; Dr. A. Wood-Smith, North Berwick; Stockport Infirmary, Secretary of; Lieutenant-Colonel Henry Smith, I.M.S., Amritsur; Mr. R. Scruby, Lond.; Mr. D. H. Shuttleworth-Brown; S. G.; Dr. J. W. Stenhouse, Manchester; Dr. Edgar Schuster, Oxford; S. H. T.

T.—Taunton and Somerset Hospital, Secretary of; Mr. G. Lestock Thornton, Exmouth; Mr. Georg Thieme, Leipzig; Mr. E. L. Tattersall, Clayton-le-Moors; Mr. H. M. Tod, Lond.

U.—Under-Secretary of State for Foreign Affairs, Lond.

V.—Messrs. Gerth Van Wyk and Co., Lond.; Dr. Frederic Vicars, Madrid; Dr. B. Valverde, St. Paul.

W.—Messrs. J. Williams and Son, Bradford; Woodhall Spa Co., Woodhall Spa, Secretary of; Dr. L. Waldstein, Hastings; Messrs. F. Williams and Co., Lond.; West London Post-Graduate College, Secretary of; Dr. Walter G. Walford, Lond.; Women's Imperial Health Association, Lond.; Messrs. J. Wright and Sons, Bristol; Dr. A. M. Webber, Nottingham; Women's Industrial Council, Lond., Secretary of; Dr. Wanostrocht, Kingston; Mr. L. E. G. de Woolfson, Swansea; West London Medico-Chirurgical Society, Secretary of; Dr. A. D. Waller, Lond.; Mr. W. Wale, Lond.; Dr. S. Russell Wells, Lond.; Dr. F. M. Williams, Plymouth.

Y.—Yost Typewriter Co., Lond.

Z.—Messrs. Charles Zimmermann and Co., Lond.; Dr. Y. Zaki, Cairo.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. G. H. Adam, West Malling; Mr. E. Arnold, Lond.; Ardath Tobacco Co., Lond.; Ashwood House, Kingswinford; Professor H. B. Allen, Melbourne.

B.—Dr. H. N. Burroughes, Lond.; Barrett Manufacturing Co., Manager of; Burton-on-Trent Infirmary, Secretary of; Dr. W. S. Byrne, West Croydon; Dr. R. A. Bennett, Torquay; *Barrow News and Mail*, Manager of; British Drug Houses, Lond.; Messrs. Burgoyne, Burbidges, and Co., Lond.

C.—Dr. R. C. Crooke, Aigburth; Miss Challands, Newmarket; Mr. L. E. Creasy, Lond.; Messrs. D. Cooper and Co., Huntingdon; Mr. R. S. Collier, Ripon; C. H. W.

D.—Dr. W. T. Dougal, Pittenweem; Doncaster Royal Infirmary, Secretary of; Dr. J. W. Duffus, Port Elizabeth; Dr. Mary C. De Garis, Tibooburra; Mr. M. Doubble, Luton; Mr. H. M. Davies, Lond.

F.—Major H. C. French, R.A.M.C., Imtarfa; F. H.

G.—Messrs. W. Goldsmith and Co., Lond.; Dr. S. Gill, Formby; Miss H. E. Grinling, Woolwich; Mr. W. N. Gibb, Lond.

H.—Mr. J. Heywood, Manchester; Messrs. Hirschfeld Bros., Lond.; Dr. G. H. Hume, Newcastle-on-Tyne; Captain W. L. Harnett, I.M.S., Gauhati; Dr. J. H. Head, Cloughjordan; Dr. G. M. Harston, Hong-Kong; The J. F. Hartz Co., Toronto; Major Hopkins, R.A.M.C., Temple Ewell; Dr. W. Hunter, Lond.; Dr. J. Holland, Swindon; Mr. F. E. Caulfeild Houghton, Dorrington.
